As we postulate two independent events in the pathway of lectin-dependent T-cell triggering, and as the whole activation process is dependent on Ia-positive accessory cells[2–4], we investigated whether or not both steps show similar cellular requirements. Normal spleen cells were passed over Ig–anti-Ig columns[13] with or without previous treatment with monoclonal mouse anti-I-A antibodies[14]. Effluent cells from the columns were then either simply cultured with Con A (to assess the effectiveness of accessory cell depletion) or tested for their ability to acquire responsiveness to growth factors after a short exposure to Con A. As we reported previously[4] and as shown in Table 1, although depletion of B cells has no influence on the T-cell response to Con A, concomitant depletion of I-A-bearing cells results in the abolition of the responses. Such responses are, however, largely restored when preformed growth factors are added to the cultures. As already pointed out, the factors are not mitogenic in the absence of Con A (expts. 1, 2). These results indicate that Con A responses are dependent on the presence of accessory cells, because these Ia-positive cells are necessary for the generation of growth factors.

The experiment presented in Fig. 2 shows that the first step in

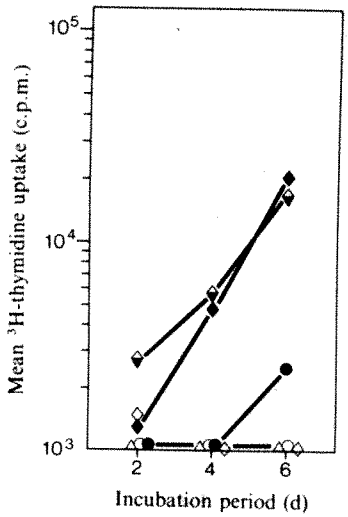

Fig. 2 Direct induction of responsiveness to growth factors in purified T cells by a short pulse of Con A. C_3H/HeJ spleen cells were treated with anti-I-A antibodies and passed through an anti-Ig column as described in Table 1, then cultured (2×10^5 ml^{-1}) in normal medium (○) or in medium containing 5 μg ml^{-1} Con A (●), a 50% final concentration of CM (◇) or both Con A and CM (◆). The same cells were also exposed to 5 μg ml^{-1} Con A for 4 h, washed five times in medium containing 20 mg ml^{-1} α-MM and cultured in medium (△) or in CM (◆).

triggering is independent of accessory cells. Purified T lymphocytes, depleted of Ia-positive cells, which do not respond to growth factors, acquire responsiveness to such growth factors during a 4 h treatment with Con A. After this short pulse, Con A is no longer required, but cell growth depends entirely on the presence of growth factors. We conclude that a direct interaction of the mitogenic lectin with the responding T cells is initially necessary for induction. Furthermore, this interaction is independent of the requirement for lectin and accessory cells in the generation of growth factors.

As we have shown before, responsiveness to growth factors is the result of the expression on the surface membrane of an acceptor site for those molecules[6]. We investigated whether or not cells pulsed with Con A for 4 h (which no longer required

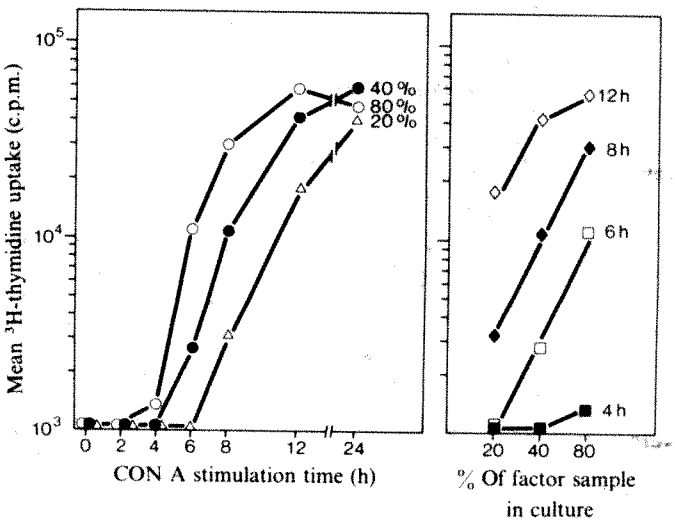

Fig. 3 Induction of T-cell growth factors in spleen cell cultures stimulated by Con A. C_3H/HeJ spleen cells (5×10^6 ml^{-1}) were cultured as described in Fig. 1 legend, in the presence of 5 μg ml^{-1} Con A. At the indicated times, CM from these cultures were collected, supplemented with 20 mg ml^{-1} α-MM and tested for growth-promoting activity in T-cell blasts which had been grown in standard CM for over 2 weeks. The test cultures contained 10^4 blasts in 0.2 ml and were supplemented by 80%(○), 40%(●) or 20%(△) concentrations of each supernatant. The results shown are the mean ^{3}H-thymidine uptake in triplicate cultures 3 days later. In the right hand panel, the same results are plotted to show the titration of the growth-factor activity in CM recovered after the various incubation periods. ◇, 12 h; ◆, 8 h; □, 6 h; ■, 4 h.

Con A for responding to growth factors) already bear such acceptor sites on the surface membrane. Acceptor sites were assayed by their ability to absorb out T-cell-specific growth-promoting activity from supernatants. Con A-pulsed cells were compared with normal spleen cells and with T-cell blasts. As shown in Table 1 (expts 3, 4), spleen cells exposed to Con A for 4 h have more acceptor sites for growth factors than normal spleen cells, but not as many as do full blast cells, which are, of course, much larger.

The present results demonstrate that direct interaction of a mitogenic lectin with purified T-cell populations does not trigger them into proliferation, but it induces, in a relatively short time, surface membrane expression of functional receptors for growth factors. In addition, the mitogenic lectin induces the production of growth factors in a process which depends on accessory, Ia-positive cells.

Assuming that T-cell triggering, in both allogenic and restricted responses, is not fundamentally different from the lectin-dependent responses studied here, we may speculate on the physiological significance of the two independent events which seem to be strictly necessary for induction. Thus, the bifunctional role of mitogenic lectins may be equivalent to the role of antigen and major histocompatibility complex products on accessory cells in the process of specific T-cell induction.

Mouse anti-I-A antibodies were provided by Dr H. Lemke.

Expression of V-region-like determinants on Ig-negative precursors in murine fetal liver and bone marrow

IDIOTYPES, as defined by Oudin[1], are antigenic markers associated with antibodies produced by a single individual. The demonstration of 'individual antigenic determinants' on human myeloma proteins[2] introduced the concept of idiotype as a clonal marker of Igs. However, as the operational definition of an idiotype is based on the specificity of anti-idiotype antisera, the extent of cross-reactivity of a particular idiotype, and therefore the definition of idiotype, depends on the criteria set for the preparation of reagents. In fact, a number of 'public' or 'cross-reactive' idiotypes are currently described which are produced by all individuals of a strain or species or even by different species[3]. Yet, idiotypes are exclusively considered as markers of

0028-0836/79/290241—03$01.00

© Macmillan Journals Ltd 1979

V-gene products defining groups of related Ig molecules. The basic concept of Jerne's network theory[4], however, postulates that the universes of idiotypes and of antigens are identical. As a consequence, the finding of idiotype-cross-reactive determinants on non-Ig molecules should be the rule. We have observed[5] that a class of polyclonally distributed mitogen receptors on splenic B cells bear determinants cross-reactive with the public idiotype of the J558 myeloma protein of BALB/c origin. We have investigated the possibility that this finding might be related to the mechanism of generation and regulation of the antibody repertoire. Having no indications on the growth regulation of B-cell precursors, we started to investigate the antigenic relationship between Ig idiotypes and mitogen receptors on those cells. We report here the cross-reactivity between several germ-line idiotypes and non-Ig surface structures expressed on cells present in haematopoietic tissues. We hypothesise that growth receptors on precursor B cells have determinants cross-reactive with germ-line V-gene products, and that precursor cells are driven and selected by interactions between these receptors and molecules with anti-idiotype specificity also belonging to an incipient network transmitted in the germline.

Fetal livers were collected from BALB/c or (DBA/2× C57BL/6) F_1 embryos from day 13 to 15 of timed pregnancies. Fetal liver at that age does not contain detectable numbers of B cells as defined by surface Ig expression or reactivity to lipopolysaccharide (LPS)[6,7]. Adult bone marrow and spleen were obtained from BALB/c and C57BL/6 mice. We have used indirect immunofluorescence to detect the membrane expression of IgM and IgD, LPS-receptors[8] and determinants cross-reactive with a number of idiotypes of likely germline origin[9], namely the idiotypes on the following BALB/c myeloma proteins: J558 ($\alpha\lambda_1$, anti-α-1,3 dextran), W3129 ($\alpha\kappa$, anti-α-1,16 dextran) TEPC15 ($\alpha\kappa$, anti-phosphorylcholine), MOPC460 ($\alpha\kappa$, anti-dinitrophenyl) and MOPC104E ($\mu\lambda_1$, anti-α-1,3 dextran). Antisera to the first three proteins were raised in mice[5,10] while anti-MOPC104E was made in guinea pigs tolerant to mouse Ig. Three different anti-MOPC460 idiotypes were compared; conventional BALB/c, and rabbit antisera, and a monoclonal antibody[12]. Although all antisera reacted only with the immunising and with idiotypically cross-reactive proteins, they were additionally absorbed on Sepharose-coupled IgM, IgA, IgG, κ and λ myeloma proteins and pooled mouse Igs. Anti-J558 and anti-MOPC460 idiotypes were antibodies purified by affinity chromatography. As controls, an IgG1 fraction of a BALB/c anti-SRBC antiserum, the monoclonal antibody Sp-2 (IgG2b anti-SRBC)[13] and normal serum IgG from A/J mice were used. All reagents were labelled with trinitrophenyl[14] or arsonate[15] and used in indirect immunofluorescence[5,16].

Table 1 shows results of staining fetal liver, adult bone marrow and spleen cells with these reagents. All anti-idiotypes, but not normal IgG or anti-SRBC antibodies, stained a sizeable proportion of IgM-positive spleen lymphocytes (11–16% of all B cells). Nearly all cells stained by anti-idiotype were $\mu^+\delta^-$, while the majority of cells expressing LPS-receptors were $\mu^+\delta^+$ suggesting that the former are less differentiated than the latter. A relatively small proportion of fetal liver cells (0.6–1.2%) were also stained by the anti-idiotype reagents, while no cells expressed either Igs or LPS-receptors, or nonspecifically bound normal IgG. In bone marrow, anti-idiotypes stained ~4% of the total

Table 1 Presence of idiotype-cross-reacting structures on mouse fetal liver, adult bone marrow and adult spleen cells

Reagent	% Positive cells: Fetal liver (day 13–15)		Adult bone marrow: Total	Adult bone marrow: μ^+	Adult spleen	
Anti-Igs	<0.04					
Anti-μ	<0.04		3.4		44.3	
Anti-J558	0.73		4.0	1.0	6.9	
Anti-MOPC460*	0.82		3.6	1.2	6.6	
Anti-W3129	0.89	all μ^-	4.1	0.8	4.9	all μ^+
Anti-TEPC15	1.2		4.1	1.2	4.9	90% δ^-
Anti-MOPC104E	0.60		ND		5.5	
BALB/c IgG1 aSRBC	<0.05		ND		ND	
Sp-2 (IgG2b aSRBC)	<0.05		ND		<0.05	
Normal A/J IgG	<0.05		ND		<0.1	
Anti-LPS-R	<0.04		0.8	0.7	7.5	all μ^+ 80% δ^+

Anti-Igs and anti-μ antibodies were labelled with tetramethylrhodamine isothiocyanate. All anti-idiotypic antisera and anti-LPS-R antiserum[7] were labelled with trinitrophenylsulphonic acid and their binding to cells detected by exposure to fluorescein-conjugated anti-dinitrophenyl antibodies. Binding of guinea pig anti-MOPC104E was also detected with fluorescent rabbit anti-guinea pig Ig antibodies. The two methods of indirect immunofluorescence gave comparable results. Anti-δ antiserum was labelled with arsonate and detected with rhodamine-labelled rabbit anti-arsonate antibodies. Living cells in suspension in medium containing 10% fetal calf serum and 20 mM NaN_3 were exposed to one of the anti-idiotypic reagents for 30 min in ice, washed and exposed to the detecting reagent (see refs. 5, 12 for details). All cell samples strained with anti-idiotype or anti-LPS-R were counterstained with anti-μ. Spleen cell samples were also counterstained with anti-δ. The stained samples were observed under a fluorescence microscope (Zeiss Photomikroscop II or Leitz Orthoplan), equipped with vertical illuminators and combinations of filters and dichroic mirrors specific for fluorescein and rhodamine. Total cells in each field were counted in phase contrast. At least 2,500 cells in fetal liver samples, and 1,000 cells in bone marrow and spleen samples were counted in each experiment and for each reagent. The figures reported here are average values of six experiments with fetal liver cells, three experiments with bone marrow, and seven experiments with spleen cells from different strains, as we did not observe differences in frequency of positive cells among all the strains tested.

* The three different anti-MPOC460 idiotype antisera gave comparable results.
ND, Not determined.

Anti-W3129 was labelled with arsonate and detected with rhodamine-labelled rabbit anti-arsonate antibodies. Anti-MOPC104E was used unlabelled and detected with rhodamine-labelled rabbit anti-guinea pig antibodies. Anti-J558, anti-TEPC15 and anti-MOPC460 were labelled with trinitrophenylsulphonic acid and detected with fluorescein-labelled anti-dinitrophenyl. The cell suspensions were exposed to a pair of anti-idiotypic antibodies for 30 min in the cold, washed and exposed to a mixture of the fluorescent detecting reagents. Positive cells out of the total cell population were counted as indicated in Table 1 legend. For the evaluation of 'double' versus 'pure' cells, each field was observed under specific illumination for fluorescein and for rhodamine. At least 100, in most cases 200, positive cells were scored in each combination.

cells, the majority of which were μ^-. None of the cells binding anti-idiotypes contained intracytoplasmic IgM, as demonstrated in experiments (not shown) where cells were stained on the membrane with anti-idiotypes, and in the cytoplasm, after fixation with anti-μ antibodies. It seems, therefore, that these cells are not those described in bone marrow and fetal liver by Raff *et al.*[17].

Confidence on the specificity of the anti-idiotype staining of Ig-negative fetal liver and bone marrow cells was provided by the lack of binding in the same staining conditions of other reagents such as mouse anti-sheep red blood cell (SRBC) or rabbit anti-LPS-receptor (LPS-R) antibodies. It is also clear that the molecules detected by anti-idiotypes on fetal liver are not idiotypes of passively acquired material IgG, as no cells were detectable in the same samples with anti-mouse Ig+L antibodies.

Further evidence for specificity of anti-idiotype binding to target cells was provided by double-staining experiments shown in Table 2. Note that, although we consistently observed the presence of two such idiotype-cross-reactive structures on the same cells both in spleen and fetal liver, a proportion of the positive cells was stained in all cases by only one reagent in the pair.

Table 3 shows results of experiments designed to characterise the membrane structures detected by some anti-idiotypes. The binding of anti-J558 and anti-MOPC104E idiotypes, but not that of anti-MOPC460 idiotype, was specifically inhibited by α-1,3-containing dextran. These results suggest that the staining of fetal liver cells, as well as that of spleen cells[5], by anti-J558 and anti-MOPC104E idiotypes is a specific reaction between anti-idiotypes and a membrane structure which is (or is associated with) a dextran binding site.

Having stressed the specificity of binding of purified anti-idiotype antibodies to Ig-negative cells in fetal liver and bone marrow, we must discuss the specificity of these anti-idiotype reagents. The antisera or purified antibodies used in these experiments are indeed anti-idiotypic when studied serologically for reactions with Ig molecules. On the other hand, the same reagents used to stain intracytoplasmic Igs of mature plasma cells in spleen, revealed frequencies of positive cells around 1–3%. These figures, although one order of magnitude lower than those observed by membrane staining of the same samples, were definitely higher than expected for 'individual specificities' and more compatible with V-region isotype specificities[9]. In fact, all the myeloma proteins used in these experiments carry 'public' idiotypes. It is likely therefore that the molecules we detect on the cell surface with these anti-idiotypes, do not cross-react with idiotypes in Oudin's *sensu stricto*, but rather with V-region determinants shared by related antibody molecules. Such V-region-like determinants are certainly not immunoglobulin in nature, or at least they are not associated with constant regions of known Ig isotypes (μ and L). In addition, the cross-reactivity observed here does not imply that we are dealing with products of Ig V-genes.

Functional studies in progress indicate that the cells described here are in fact B-cell precursors. Furthermore, the addition of anti-idiotypes to fetal liver and bone marrow cultures can be shown to influence B-cell development, suggesting that such idiotype-cross-reactive structures function as growth receptors. More than one specificity of idiotype-cross-reactive structure can be found on the same cells, both in fetal liver and spleen, and this parallels previous findings of multiple mitogen receptor specificities on the same B cell[18]. This is in contrast with the strict monospecificity of Ig molecules of a single cell, where all membrane Igs, both IgM and IgD, bear the same idiotype[19,20].

It is perhaps not fortuitous that such public idiotype-cross-reactive structures are present on fetal liver and adult bone marrow Ig-negative B-cell precursors. If the repertoire of antibodies is a closed network[4], and the germ-line specificities represent the main features of the system and are therefore anti-idiotypic, these 'idiotypes' on growth receptors of precursor cells would provide the internal conditions for inducing their proliferation, as well as a mechanism for selecting the desired idiotype specificities. These are minimal requirements for somatic generation and regulation of antibody diversity, and they assume that the repertoire selection is guided by idiotypes and not by combining site specificities. This proposal assumes that physiological mitogens which drive precursor B-cell development are anti-idiotypes and not the ligands to which the idiotype-bearing antibodies can bind. Only when the ligand can inhibit the reaction of anti-idiotypes with the triggering structures could we expect it to be mitogenic for precursors, as is the case for dextran[18,21]. Speculations on the selective pressures which result in antibacterial specificity of growth receptors on B cells, as well as of most myeloma proteins with antibody activity, will be developed elsewhere.

We thank Dr G. Koehler for monoclonal antibody Sp-2, Dr S. Cammisuli for anti-arsonate antibodies, and Dr J. Haimovich for anti-dinitrophenyl antibodies. We are indebted to Dr Bonnie Blomberg for anti-J558 reagents and for helpful discussions.

Table 3 Inhibition of the staining of fetal liver cells by anti-idiotypic antisera

Reagent	Inhibitor	% Positive cells	% Inhibition
Anti-J558	None	0.37	—
	Dextran B1355	0.04	89.2
	Dextran B512	0.36	2.8
Anti-MOPC104E	None	0.50	—
	Dextran B1355	0.18	64.0
	Dextran B512	0.37	26.0
Anti-MOPC460	None	0.46	—
	Dextran B1355	0.39	15.3
	Dextran B512	0.41	10.9

The staining was performed in the presence of dextran B1355 (containing α-1, 3 and α-1, 6 linkages) or dextran B512 (containing primarily α-1, 6 linkages) at a concentration of 250 μg ml^{-1}.

Tumour promoter TPA enhances transformation of human leukocytes by Epstein–Barr virus

TUMOUR-promoting phorbol esters have contributed to the concept of multiple-step carcinogenesis[1], as illustrated in the two-stage mouse skin carcinogenesis model[2]. Promoters are not significantly carcinogenic when tested alone, but decrease the threshold dose of carcinogens (initiators) and reduce the latency period for tumour appearance. 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA) and several other diterpene esters represent potent tumour promoters[3–5]. Recently, it has been shown that these promoters efficiently induce persisting genomes of oncogenic herpesviruses, particularly of Epstein–Barr virus (EBV)[6–8], resulting in high percentages of viral antigen and particle-positive cells. Other observations showed that TPA enhances *in vitro* transformation of fibroblasts previously exposed to polycyclic aromatic hydrocarbons, UV light or adenoviruses[9–12]. These studies prompted us to analyse the effect of TPA not only on virus induction in EBV genome-harbouring cells, but also on EBV-induced transformation of human cord blood lymphocytes. Our data show that low concentrations of TPA significantly enhance transformation of lymphocytes by EBV.

Initial experiments were designed to investigate the effect of various concentrations of TPA on colony formation of human cord blood leukocytes after infection by transforming EBV derived from the B95-8 line[13]. As previously described[14–16], typical 'rod-shaped' EBV-transformed colonies appeared after about 2 weeks of incubation. Figure 1 shows that cultures treated with quite a wide range of TPA concentrations showed a marked increase in the number of colonies when compared with the untreated controls. The optimal concentration of TPA was 0.31 ng ml^{-1}. In these conditions six times more colonies were counted than in cultures without TPA; transformed colonies appeared earlier and were larger in cultures kept in the presence of TPA, although the morphology of TPA-treated and untreated cultures was similar.

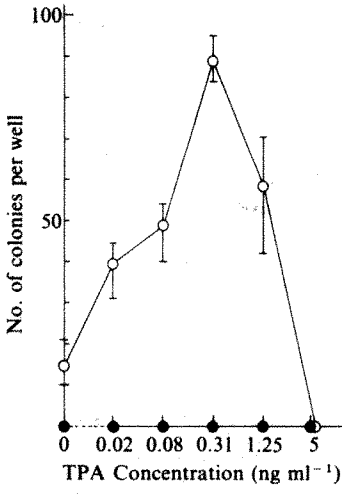

Fig. 1 Effect of TPA on colony formation of human cord blood lymphocytes after infection with EBV. Umbilical cord blood lymphocytes were prepared by a conventional Ficoll–Hypaque procedure[20], and infected with EBV derived from B95-8 cells. The virus concentration procedure has been described previously[14]. Colony formation by EBV-transformed cells in soft agar was determined as reported elsewhere[15]. The number of transformed cell colonies growing in agarose was quantitated under a low power microscope 2 weeks after infection and expressed as the mean value of four wells. The bars reveal the observed deviations. TPA was used in fourfold dilutions starting with 5 ng ml^{-1}. ●, Preparations without EBV; ○, preparations infected with EBV.

TPA has been reported to stimulate T lymphocytes specifically[17]. However, no transformed lymphoblastoid colonies were observed in cultures treated exclusively with TPA, although some differentiated cell colonies were detected. As the colonies in TPA-treated cells were also EB nuclear antigen-positive, these results show that they were indeed transformed by EBV. Similar experiments were carried out using peripheral leukocytes of an EBV-seroreactive healthy adult. The results also confirmed that at an optimal concentration of 0.31 ng ml^{-1} transformation efficiency was enhanced approximately fivefold (data not shown). Therefore, 0.31 ng ml^{-1} was used in further experiments by modifying the concentration of the virus used for transformation tests. As shown in Fig. 2, the maximal number of colonies was obtained at a virus dilution of 1:4 in all preparations tested. At this virus concentration fivefold higher counts of colonies were noted in TPA-treated cultures. The number of colonies decreased proportionally to the virus dilution, starting at a dilution of 1:4 in both types of culture. The virus–dose response was similar to that observed in previous studies[14]. At higher virus concentrations the decrease in the number of transformed colonies may be attributed to cell killing activity of the concentrated preparations[14].

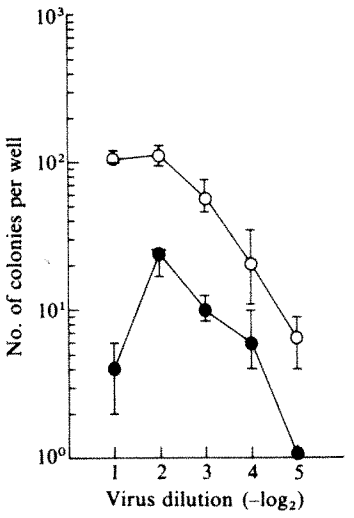

Fig. 2 Colony formation of human cord blood lymphocytes after infection with serial dilutions of EBV in the presence or absence of TPA. The procedures are the same as those outlined in Fig. 1. Cells are infected by serial dilutions of EBV and mixed with the agarose medium with (○) or without (●) 0.31 ng ml^{-1} TPA.

We then determined whether TPA also stimulates colony formation of established lymphoblastoid lines in agarose even without the addition of exogenous EBV and whether this effect is specific for EBV genome-harbouring cells. For this we used one EBV genome-negative line, BJAB, and four EBV-positive lines, P3HR-1, two Raji clones[18] and a newly established human cord leukocyte line, CBL-1 (about 2 months after establishment). The data show that except for CBL-1, TPA did not enhance colony formation of these cells. There was even a reduction in the number of colonies (15–40% less than in the control) which were also more dispersed in the presence of TPA. However, TPA caused an approximately threefold increase in colony formation in CBL-1 cells (Fig. 3).

We also investigated the effect of TPA on transformation by end-point dilution. Again, TPA increased the transformation efficiency in liquid culture systems. In the presence of 0.31 ng ml^{-1} TPA, two independent experiments yielded about fivefold higher TD_{50} per ml (7.9×10^{-5} and 2.5×10^{-5}) than in the untreated controls (1.6×10^{-5} and 5.0×10^{-4}).

© Macmillan Journals Ltd 1979

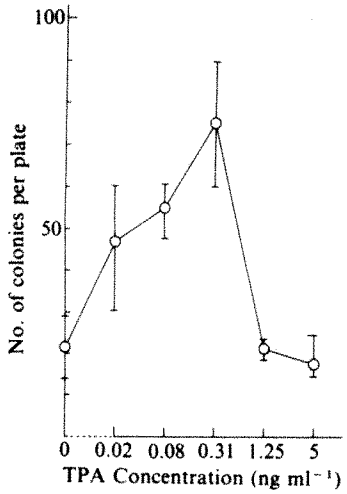

Fig. 3 Effect of TPA on cells of a newly established B95-8 EBV transformed cord blood lymphocyte line, CBL-1. The procedure for analysing the colony formation of cells from established lines was basically identical to that of the previous experiments[18]. 5,000 cells were seeded into each plate. The number of colonies was counted 7–9 days after inoculation. All values are the mean of three plates. Bars represent the deviations of these plates.

Our results indicate: (1) TPA at low molarity caused a three- to seven-fold enhancement of transformation of human leukocytes by EBV. (2) TPA does not increase the plating efficiency of three 'old' established cell lines in agarose regardless of their EBV genome state. (3) TPA enhances the plating efficiency of a newly established line in agarose. These results suggest that TPA acts on transformation steps rather than inducing nonspecific colony-stimulating factors that are known to promote cell growth in agarose[19].

Oxidant damage mediates variant red cell resistance to malaria

IT is thought that the deleterious properties of thalassaemia (thal) and glucose-6-phosphate dehydrogenase deficiency ($G6PD^-$) are balanced in the population by a conferred protection against malaria, and that some characteristic of the variant red cell acts directly to inhibit the invasion or intracellular development of the malaria parasite. Indeed, such is the case for sickle cell disorders[1,2]. Recently, Pasvol *et al.*[3], having shown that fetal haemoglobin (HbF) (in both fetal and adult cells) inhibits malaria parasite development, have suggested that the slight persistance of HbF in children with thal trait is responsible for the selective advantage of the thal gene. They have reported no difference in parasite development in the red cells of adult carriers of thal. Evidence is presented here that both α- and β-thal trait red cells from adults are refractory to parasite development because of oxidant sensitivity, and, furthermore, that fetal red cells and $G6PD^-$ cells are refractory for the same reason.

Decreased protection against oxidant damage has frequently been suggested as a mechanism by which $G6PD^-$ cells could inhibit the optimal multiplication of the malaria parasite. Etkin and Eaton have demonstrated the production of H_2O_2 by a rodent malaria parasite[4], and the insufficient protective capacity of the $G6PD^-$ cell is well known[5]. The possibility that thalassaemic cells also inhibit parasite growth by their sensitivity to oxidant stress[6] has not previously been suggested. To study the role of oxidant sensitivity in resistance to malaria, *Plasmodium*

Table 1 Sensitivity to increased oxygen of *Plasmodium falciparum* in $G6PD^-$ and α- and β-thal red cells

RBC	Expt	Parasites per 100 red cells 30% O_2	17% O_2	Relative multiplication 30%/17%

Suspensions of variant and normal red cells (5% v/v) were inoculated with less than 1/30 cell volume of cells infected with *P. falciparum* (FMG/FCR-3). Cultures were maintained by the method of Trager and Jensen[7] as described previously[1]. After 2 d growth at 17% O_2, single cultures were split and incubated in either 17% or 30% O_2 for 2 additional days. Normal parasites per 100 red cells were counted on day 4 and the relative multiplication at 30% O_2 was calculated. Differences in the counts on day 4 between experiments result from different initial infections. Parasites with abnormal morphology at 30% O_2 were of a sufficient number to indicate that intracellular development was inhibited rather than invasion blocked. $G6PD^-$ red cells were obtained by screening[8] samples collected from male Negro blood donors. β-Thal red cells were from the parents of children attending a thalassaemia clinic (mostly mothers). α-thal red cells were verified by globin chain synthesis (H. Chang, New York Hospital). $G6PD^-$ experiments 3 and 4 were on the same sample. All others are from different individuals.

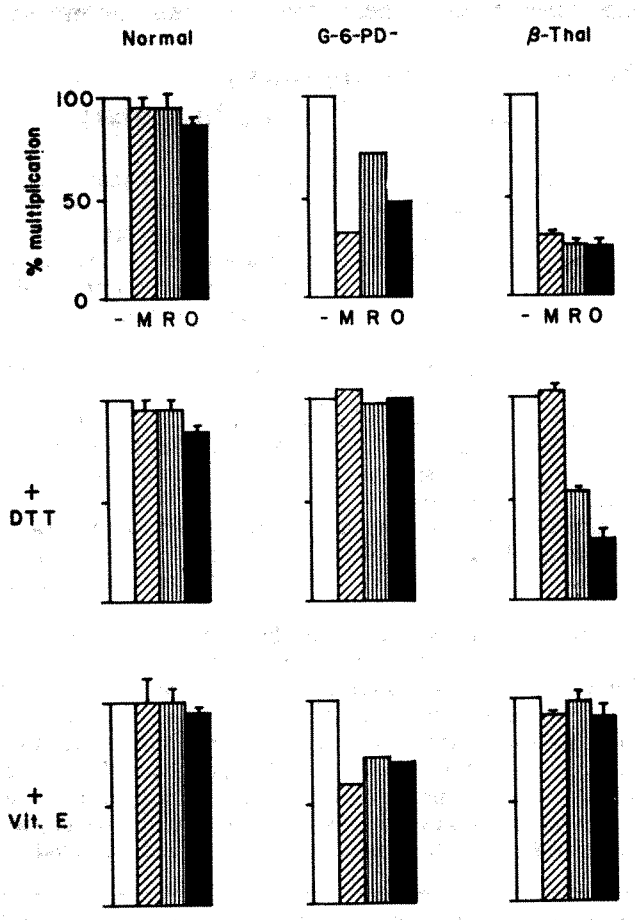

Fig. 1 Multiplication of *P. falciparum* in G6PD⁻ and β-thal red cells when oxidant damage is enhanced or inhibited. An experiment identical to that in Table 1 was carried out in the following conditions during the second 2 d: 17% O_2 (−), +2.5 μM menadione (M), +2.0 μM riboflavin (R), 25% 0_2 (O). DTT (50 μM) and vitamin E (0.2 mg ml^{-1}) were added as indicated. Height of the bars represents multiplication relative to that at 17% O_2. Error bars for normal and thal cells show one s.e.m. from three experiments (different donors). G6PD⁻ values are the means from two experiments. Neither DTT nor vitamin E had significant effects on growth in normal cells at 17% O_2.

falciparum, the human malaria parasite, was cultured in G6PD⁻, α- and β-thal trait, and HbF-containing erythrocytes in conditions which either enhanced or inhibited oxidant damage.

Cultures of G6PD⁻ and both α- and β-thal trait red cells in RPMI-1640 medium in an atmosphere of 17% O_2/3% CO_2 were inoculated with less than 1/30 volume of infected red cells. All variants supported normal multiplication of the parasite for 4 d in these conditions. The erythrocytic cycle of the parasite is 48 h and an eight- to tenfold multiplication was seen at this time. Thus, after 2 d, virtually all parasites had invaded variant cells. If cultures were then transferred to an atmosphere of 30% O_2/3% CO_2, an inhibition of multiplication occurred that was greater in G6PD⁻ and thal cells than in normal cells (Table 1) ($P<0.01$). The response of these host–parasite systems to oxidative stress was further characterised by parallel incubation in either 25% O_2, 2 μM riboflavin, or 2.5 μM menadione (Fig. 1). Riboflavin was more inhibitory to parasites in β-thal trait cells than to those in G6PD⁻ cells, while menadione and high O_2 were inhibitory to both. Thus, riboflavin and menadione have different effects on parasitised G6PD⁻ cells. Both of these agents can participate in single electron redox reactions to generate free radicals[9,10], but menadione alone can catalyse H_2O_2 production when reduced by flavin dehydrogenases[10]. Indeed, the ability of the malaria parasite to oxidise external NADPH[11] suggests that a parasite dehydrogenase may be exposed to the red cell cytoplasm and

Table 2 Multiplication in medium without gluthathione

RBC	Multiplication relative to complete medium (mean ± s.d.) RPMI-1640 −glutathione	High K^+ RPMI-1640 −glutathione
Normal	0.84 ± 0.03 ($n=4$)	0.70 ± 0.01 ($n=2$)
β-thal	0.48 ± 0.14 ($n=7$)	0.82 ± 0.02 ($n=2$)
G6PD⁻	0.32 ± 0.04 ($n=2$)	
Fetal (HbF)	0.33 ± 0.18 ($n=3$)	

Parasites were cultured for 2 d at 17% O_2 in complete RPMI-1640 and then for 2 d in either medium with or without glutathione. In two experiments, growth was also tested in medium without glutathione, but containing high potassium[22]. All experiments were on samples from different donors.

that menadione contributes to the peroxide load in the red cell by interacting with this enzyme. This interpretation is consistent with the sensitivity of G6PD⁻ cells to H_2O_2 referred to earlier. The sensitivity of thal cells to riboflavin may then be explained by a sensitivity of these cells to free radical mediated oxidation. Vitamin E (α-tocopherol), which prevents the lipid peroxidation catalysed by free radicals[12], was found to completely reverse the sensitivity of thal cells.

Parasitised G6PD⁻ cells were only partially protected by vitamin E, but dithiothreitol (DTT) was more effective. This thiol-reducing agent is expected to reduce gluthathione, providing substrate for gluthathione peroxidase, and may, like NADPH[13], protect red cell catalase. Both of these activities would result in lower H_2O_2 levels in the cell and decrease the risk to the G6PD⁻ cell from peroxide production and NADPH utilisation by the parasite. Note that DTT also protected the thal cell from menadione induced damage, presumably by counteracting the H_2O_2 produced by this agent. Mechanisms of oxidant stress and damage are notoriously difficult to identify and prove. The explanation discussed here and shown in Fig. 2 is not meant to be accurate or complete but is offered for discussion and testing.

The situation *in vivo* is not completely comparable to that *in vitro*. Oxygen concentrations of 30% and 25% are not normal physiological conditions. However, riboflavin is found in the circulation and soluble quinones are found in some foods. The observations that these substances potentiate the resistance of variant red cells to malaria infection implicate nutritional interactions in *in vivo* protection. Indeed, such ideas may explain the variable levels of resistance to malaria measured in field studies[15,16]. In addition, the culture medium RPMI-1640 contains reduced glutathione (GSH). When GSH was left out of the medium, approximating the *in vivo* situation, parasite growth was inhibited in variant cells at 17% O_2 (Table 2) ($P<0.01$). Growth in HbF-containing fetal cells was also inhibited. HbF

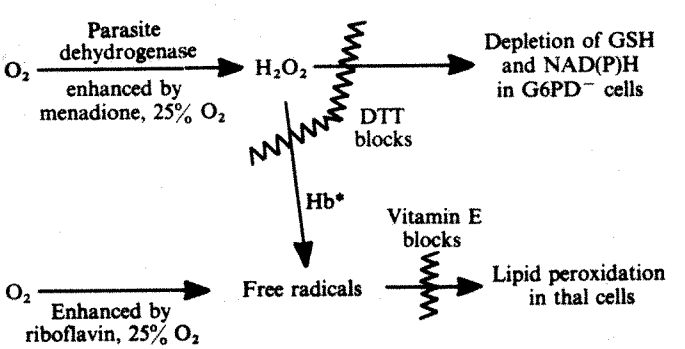

Fig. 2 Hypothetical model for the generation of oxidant damage during malaria infection of variant cells.* The interaction of H_2O_2 and HbF results in free radical production[14]. This may be enhanced in thalassaemia or HbF-containing cells.

was initially found to inhibit parasite growth in cultures in medium 199 (0.05 mg per litre GSH)[3], but this was not found here in complete RPMI-1640, which contains more glutathione (1 mg l^{-1}). Parasites in HbF cells were only inhibited in the absence of GSH. The sensitivity of fetal cells to lipid peroxidation[6] is consistent with this observation.

We have now seen that oxidant stress and oxidative damage act to limit malaria parasite multiplication in some red cell variants in conditions similar to those *in vivo*. In G6PD$^-$ cells, the production of peroxide by the parasite seems to overload the reducing capacity of the red cell. When catalase (50 μg ml^{-1}) was added to the medium to decrease H_2O_2 levels, parasites in G6PD$^-$ cells were protected, whereas those in thal cells were not (data not shown). Although some damage in the G6PD$^-$ host is prevented by vitamin E, there are other consequences of H_2O_2 exposure such as the depletion of GSH[17] and NADPH, metabolic requirements of the parasite[18,11]. *In vivo*, decreased GSH could lead to cross-linking of red cell membrane proteins[19] or Heinz body formation which may result in splenic sequestration and the selective removal from circulation of infected cells. This would explain the paucity of parasitised G6PD$^-$ cells seen in the blood of an infected heterozygous mozaic female patient[20].

As vitamin E was completely protective in thal red cells, free radical production was thought to lead to lipid peroxidation and membrane damage. To test this hypothesis, parasites in thal trait cells were cultured in a glutathione-free medium containing high (105 mM) K^+. One of the consequences of oxidative damage to the red cell membrane would have been increased cation permeability[21]. The high K^+ medium prevents red cell K^+ loss and maintains intracellular levels even when the membrane leaks. This protected the parasites from inhibition (Table 2). Thus, the primary lesion in the infected thal cell must be to the membrane. The parasite's requirement for a high potassium environment has previously been shown in the sickled HbAS cell which also leaks potassium and inhibits parasite metabolism[22].

Although HbF is clearly inhibitory in its own right, the adult thal trait is also resistant. Both the fetal red cell (data not shown) and the thal red cell are sensitive to riboflavin-induced oxidant damage. The basis for this sensitivity is being investigated. Their sensitivity is qualitatively different from that of G6PD$^-$ cells; the protection against malaria conferred by these traits may also differ. Nevertheless, the model of oxidant sensitivity presented here provides experimentally verified mechanisms for the resistance of these variants to malaria and for the subsequent enhanced survival of the carriers of these genetic traits.

I thank Drs M. Bestak and H. Chang for thalassaemia trait and fetal cord red cells and the New York Blood Center for samples from blood donors. This work was presented in part at the 1978 meeting of the American Society of Hematology[23].

Nucleotide sequences of the attachment sites of bacteriophage Mu DNA

THE temperate bacteriophage Mu has the remarkable ability to insert its DNA in apparently random sites of the *Escherichia coli* chromosome (1–3). All Mu prophages have the same gene order[4], and the finding that the prophage and the phage maps are identical suggests that specific sites (attachment sites) at the ends of the Mu genome are used for the integration of Mu[5]. Phage particles do not contain the excised, free form of the Mu DNA; instead, the Mu genome is flanked by what seems to be heterogeneous bacterial DNA[6,7]. The variable DNA at both ends of Mu is thought to be generated when Mu DNA is transposed to many new chromosomal sites during replication and is subsequently packaged into phage particles together with adjacent host DNA. The nucleotide sequence analysis of the ends of Mu DNA reported here substantiates this hypothesis and identifies the attachment sites of Mu. Structural features of the attachment sites are presented.

The material for sequencing was derived in the following way. DNA fragments containing the Mu ends (Mu plus host DNA) were purified from mature phage DNA and inserted into plasmids. The cloning of the *Hin*dIII fragment, which contains the c-terminal or left end of Mu, has been described elsewhere[8]. Right-end fragments generated by a mixture of *Eco*RI and *Sal*I or *Eco*RI and *Bam*HI were inserted into plasmid pBR322 which had been cleaved with the appropriate restriction nucleases. The structures of these recombinant plasmids are outlined in Fig. 1; plasmids containing the left or right end of Mu are called pLM and pRM, respectively. The sequencing strategy (Fig. 2) involved end-labelling of small juncture fragments with [γ-^{32}P]ATP and polynucleotide kinase, separation of the two labelled ends by recleavage with restriction nucleases and deduction of the sequence by the chemical modification procedure of Maxam and Gilbert[9].

The sequence information we have obtained from three plasmids containing the left or right end of Mu demonstrates the validity of the concept that Mu DNA is covalently linked to variable host DNA sequences. For example, sequencing gels of two different left-end juncture fragments from pLM44 and pLM54, both read from the same 5′-labelled *Hpa*II site in Mu DNA into host DNA (Fig. 2), show sequences which match perfectly up to a certain nucleotide but which differ beyond this. In Fig. 3 we have aligned the juncture sequences of pLM and pRM plasmids. For comparison we have included both juncture sequences from a Mu prophage inserted in *lac*Z; details and implications of this latter experiment will be described elsewhere. All pLM plasmids contain a common sequence located next to a variable region different in each plasmid. The same is true for all pRM plasmids. We regard the common sequences as Mu and the variable sequences as host DNA, such that the end points of the Mu genome coincide with the first nucleotides of the common sequence. Although the host DNA sequences are largely different from one another, they show similarities in sequences directly adjacent to the Mu ends. At the left end in two out of four plasmids, the Mu sequences are preceded by

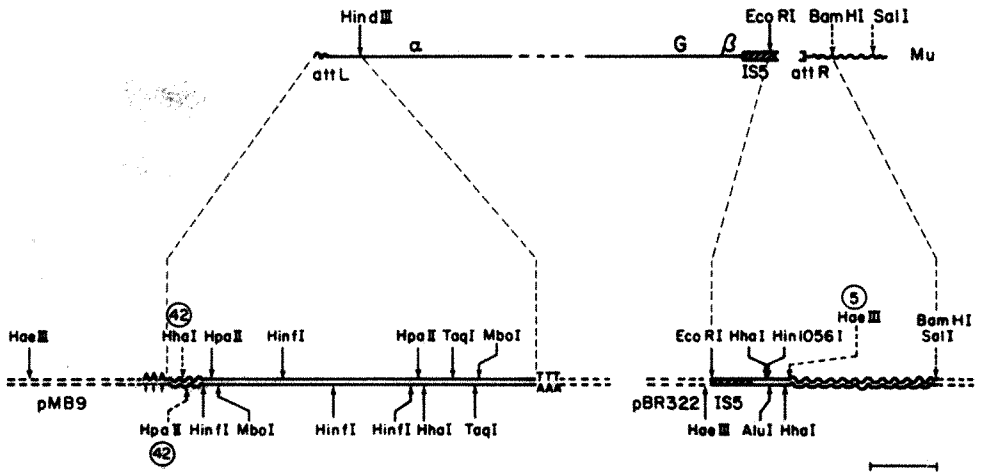

Fig. 1 Cloning of end fragments of the Mu genome and restriction enzyme cleavage map. attL: the leftmost 1,000-base pair long *Hin*dIII fragment of Mu DNA was isolated and inserted into the *Eco*RI cleavage site of pMB9 after tailing with terminal transferase[8]. A preliminary cleavage map of this fragment has been published previously[19], and we include here only cleavage sites that have been used for the identification of juncture fragments and the sequence analysis. pLM44, pLM54 and pLM42 were used here. attR: Mu 445-8 phage DNA[20] carried an additional *Eco*RI cleavage site (R.K. and D.K., unpublished) which is located in the region shown to be IS*5* (ref. 21). The rightmost *Eco*RI fragment of Mu 445-8 DNA was isolated, recleaved with either *Sal*I or *Bam*HI at statistically occurring sites in the heterogeneous host DNA and inserted into pBR322 (ref. 22), which had been cleaved with *Eco*RI + *Sal*I or *Eco*RI + *Bam*HI, respectively. The ligation conditions used were as described by Murray and Murray[23]. Three plasmids were analysed, pRM5, containing an *Eco*RI–*Sal*I insert 800 base pairs long, pRM8, containing an *Eco*RI-*Sal*I insert of 2,500 base pairs, and pRM1, containing an *Eco*RI-*Bam*HI insert of 400 base pairs. The heterogeneous *Eco*RI fragment overlapping attR of Mu 445–8 was also cleaved with various restriction enzymes to detect cleavage sites in the constant Mu part, which could then be used to determine the presence of Mu DNA in the pRM chimaeric plasmids. No cleavage sites were detected for *Hpa*II, *Hae*III and *Mbo*II, whereas *Alu*I, *Hha*I and *Hin*1056I cleaved at least once. Solid lines represent Mu DNA, wavy lines indicate host DNA, specific in each plasmid but different from one plasmid to another, and broken lines represent vector DNA. Cleavage sites are indicated by solid line arrows, broken line arrows labelled with numbers indicate that the cleavage site is only present in the plasmid indicated.

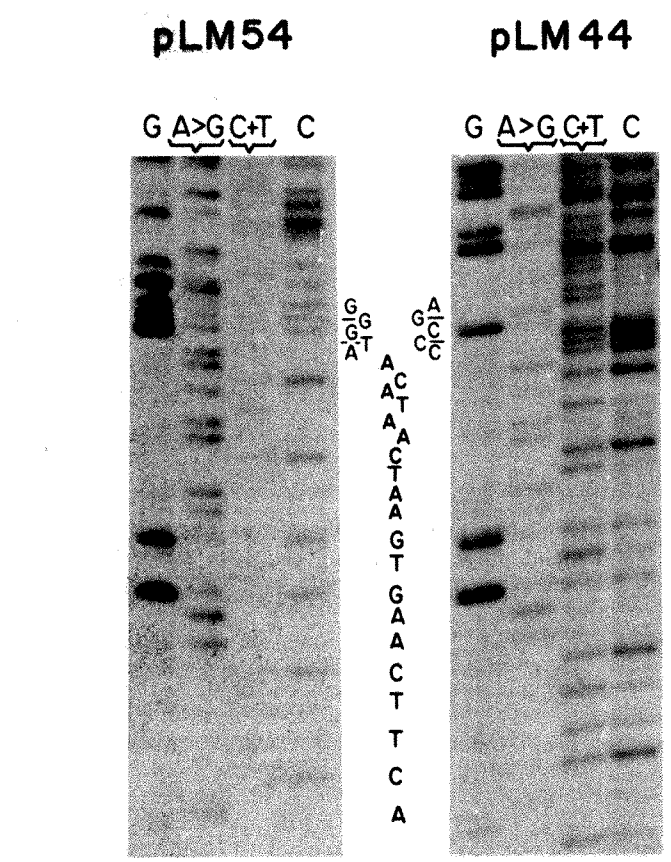

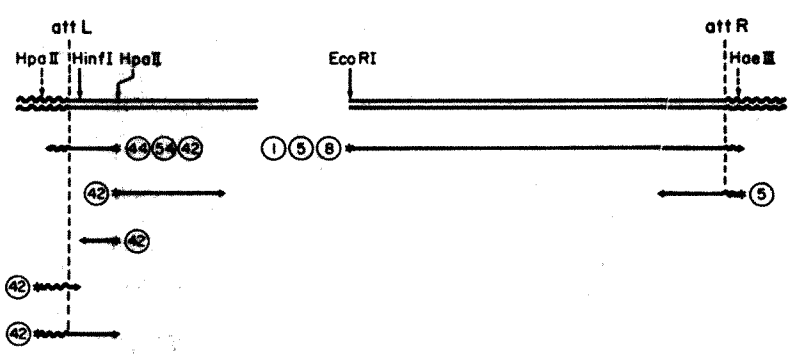

Fig. 2 Sequence analysis. Autoradiographs of sequencing gels showing the attL host DNA–Mu DNA junctures in pLM44 and pLM54. The autoradiographs show parts of the sequences (starting at nucleotide 19 of attL in Fig. 3) read from a labelled 5′ *Hpa*II end within Mu DNA through the juncture into the host DNA. Electrophoresis of the DNA fragments generated in the reactions described by Maxam and Gilbert[9] was on 20% polyacrylamide gels containing 7 M urea. For sequencing the attL juncture fragments of pLM44 and pLM54, the plasmids were digested with *Hpa*II, labelled with [γ-^{32}P]ATP and polynucleotide kinase[9], and recut with *Hae*III. The juncture fragments, now labelled only at the *Hpa*II site in the Mu part, were isolated from 2% agarose gels and sequenced. pLM42 contains a *Hpa*II as well as a *Hha*I site in the host DNA. The *Hha*I fragment overlapping the pLM42 attL junction was isolated after separation on 3.5% polyacrylamide gels; it was then recut with *Hpa*II and end-labelled. The two labelled internal *Hpa*II fragments were isolated from a 5% acrylamide gel, recleaved with *Hin*fI and the products separated on 8% polyacrylamide. All four labelled fragments were sequenced. In addition, the strands of the *Hpa*II juncture fragment of pLM42 were separated as described by Maxam and Gilbert[9] and sequenced. pRM plasmid DNAs were linearised with *Eco*RI, end-labelled and recleaved with *Hae*III to separate the two labelled ends. The juncture fragments were then purified on 2% agarose gels, re-isolated and sequenced. pRM5 contains an *Hae*III cleavage site in the bacterial DNA very close to the juncture. This site was labelled and the sequence was read over the juncture into Mu DNA. Solid lines indicate Mu, broken lines vector, and wavy lines host DNA, respectively. Asterisks mark the ^{32}P-labelled ends of a fragment. The arrow indicates the direction and length of the sequence that was read. We consider those sequences which were read from only one strand as preliminary. Numbers in circles refer to plasmid numbers and indicate that fragments from the corresponding plasmid were sequenced.

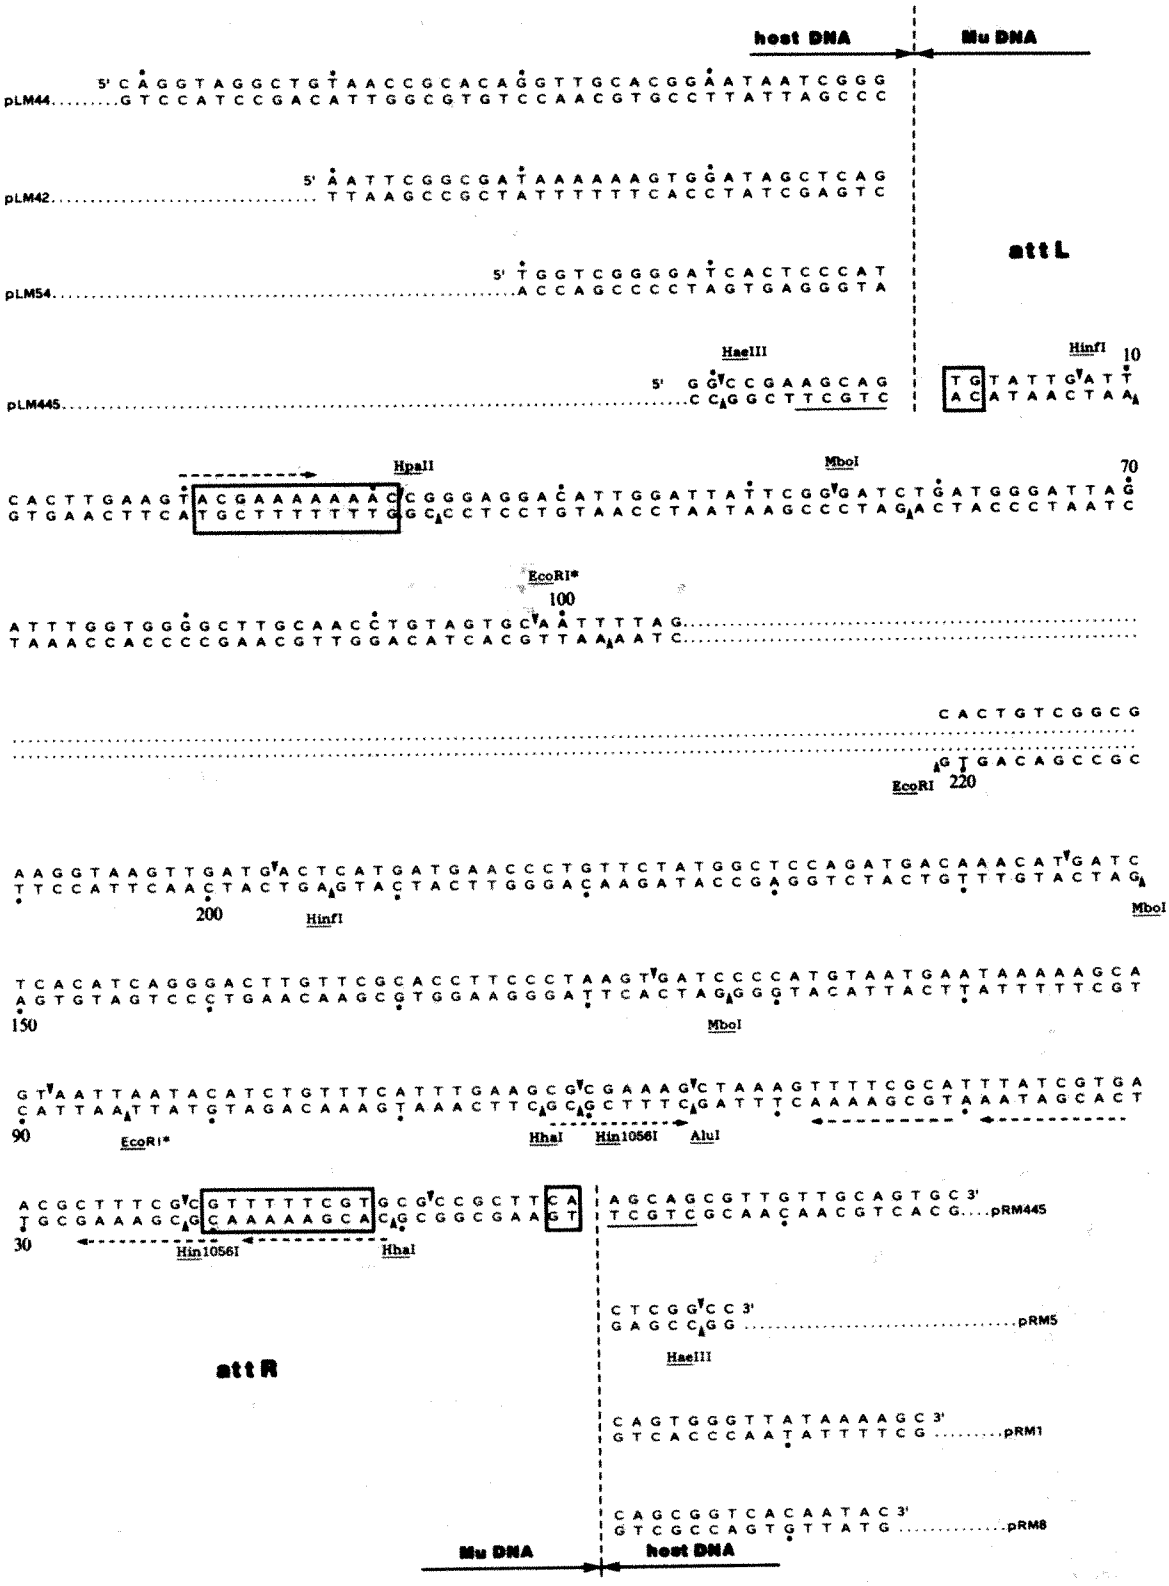

Fig. 3 Nucleotide sequence of the ends of bacteriophage Mu DNA. The central part of the sequence shows the common region of four pLM and four pRM plasmids. The unique sequences for the individual plasmids are shown to the left and right of the common sequence. The juncture sequences of pLM445 and pRM445 are included for comparison and will be described in detail elsewhere (manuscript in preparation); they show the juncture sequences of a Mu prophage inserted into the *lacZ* gene. Sequences found in inverted order at both ends are in solid line boxes. Broken line arrows indicate the sequence PyPuCGAAAA. The 5-base pair duplication of adjacent host sequences in pLM445 and pRM445 is underlined. The *Mbo*I and *Hin*fI cleavage sites in attR and all *Eco*RI* cleavage sites were inferred from the sequence; the presence of all other restriction enzyme cleavage sites have been demonstrated by mapping. Numbers indicate distances from the junctures in base pairs. Note that the attR sequence is derived from Mu 445–8 DNA; Chow *et al.*[20] have shown that in Mu 445–8 only ~150 base pairs next to the juncture are Mu DNA.

5'CAG and in one case by 5'CAT. At the right end in two of the four junctures the Mu sequence is followed by 5'CAG. We consider this to indicate some specificity of Mu insertion. In fact, it is possible that the specificity in host DNA sequences is more extensive and covers the first nucleotide(s) of the common sequence so that the definition of the exact end points of the Mu genome becomes somewhat arbitrary. Our positioning of these points, however, has been corroborated by the sequence analysis of two prophage junctures where the host DNA sequence is known (manuscript in preparation).

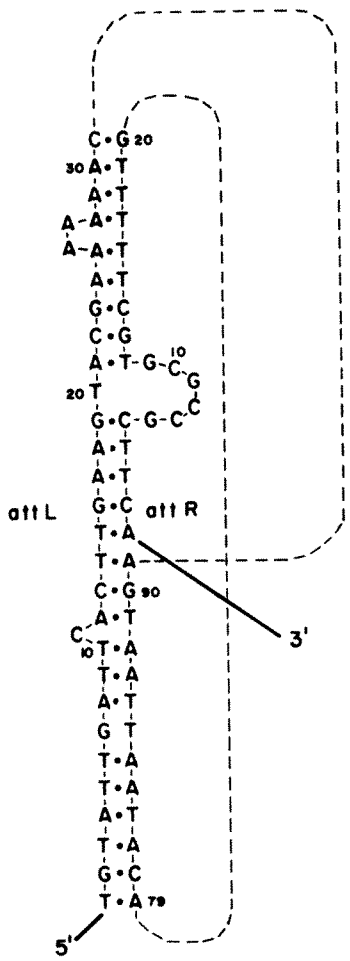

Fig. 4 Similar sequences at Mu attL and Mu attR. To illustrate the arrangement of similar sequences at the two Mu attachments sites, the DNA is presented in a single-strand stem-loop structure. Numbers indicate distances from the Mu–host DNA junctures. Nucleotides 1–20 of attR are paired with nucleotides 15–31 of attL and nucleotides 1–14 of attL are paired with nucleotides 79–91 of attR. Correct base pairing is indicated by dots.

The presence of defined juncture points between Mu and host DNA at both ends of the Mu genome suggests that specific Mu DNA sequences (hereafter referred to as Mu attL and Mu attR for left and right end attachment sites, respectively) at or near the junctures represent recognition sites for enzymes involved in Mu integration. In this respect, it should be noted that only one Mu-specific function, the protein coded for by gene *A*, is implicated in the integration process[10]. Assuming that both attachment sites are recognised by this protein we expect to find structural similarities between attL and attR. A first inspection shows that sequence similarities of the two attachment sites are confined to two base pairs at the very end and to a stretch of nine nucleotides (containing one mismatch) located between positions 21 and 31 in attL and between positions 12 and 20 in attR. Moreover, the sequence 5'PyPuCGAAAA which is part of the 9-base pair sequence common to both attachment sites is repeated with minor modifications five times within the first 62 nucleotides in attR but not in attL. This sequence might play a major part in the interaction of protein(s) with the attachment sites. Closer examination reveals that the first 31 nucleotides in attL are almost completely present in attR, but are arranged differently: the first 14 base pairs of attL are found 79 base pairs away from the juncture in attR, whereas nucleotides 15–31 in attL seem to correspond to the first 20 nucleotides of attR (Fig. 4). Whether this sequence arrangement has functional significance or is the result of evolutionary development remains to be determined.

In these structural aspects the Mu attachment sites differ markedly from IS sequences and other transposable elements, where the ends have been shown to contain more or less identical sequences arranged in inverted orientation[11–13]. The sequence differences encountered between Mu attL and Mu attR could reflect functional differences of the two attachment sites during integration and in the DNA replication and packaging processes. The insertion mechanisms of Mu and other transposable elements, however, may be closely related, as is indicated by the finding that Mu insertion, like the insertion of IS*1* (refs 12, 14), IS*2* (ref. 13) and Tn*3* (ref. 15) results in a duplication of host DNA at the host target site (Fig. 3)[16,17].

The sequences of the ends of Mu DNA shown here and those determined independently by Allet[18] differ substantially. The interpretation of Allet's sequencing data, particularly the location of the Mu ends and the finding of a 5-base pair inverted repeat sequence at the ends, is not consistent with our data. In addition, the sequences beyond the *Alu*I cleavage site at the attR end in Allet's sequence are completely different from the sequence we have determined for that region.

Degradation of DL-leucine with longitudinally polarised electrons

MOLECULAR asymmetry represents a striking characteristic of living organisms and their products. The precise mechanism(s) involved in the origin of this asymmetry in nature is not known, although Vester[1] and Ulbricht[2] proposed that it may have originated through preferential destruction of one enantiomer of a racemic mixture by spin-polarised electrons arising from β-decay, or circularly polarised bremsstrahlung produced during their deceleration. However, tests of this hypothesis have yielded results which were either negative or, at best, of borderline significance[3]. Recently, however, Bonner *et al.*[4,5] reported the asymmetric degradation of the amino acid DL-leucine on irradiation with a beam of longitudinally polarised 120-keV electrons (degree of polarisation 10–27%). Electrons polarised

† The error is $\sigma/\sqrt{n}$ where σ is the standard deviation from the average %D for the n P or AP samples.

with their spins antiparallel (AP) to their momenta were reported to cause preferential destruction of the D-enantiomer. Moreover, the L-enantiomer of leucine was reported to be preferentially destroyed by electrons polarised with their spins parallel (P) to their momenta. These results were of special interest as electrons emitted in β-decay have AP spins and also it is the L-isomer of leucine which occurs in nature. The precise physical processes responsible for such an asymmetric degradation remain unclear. We report here that using an electron source[6] which provides a much higher degree of polarisation (typically 43%), we have reinvestigated the effect of irradiation of DL-leucine with longitudinally polarised electrons. In particular, the increased spin polarisation was expected to result in a more pronounced asymmetric degradation. However, no asymmetric decomposition was observed.

The polarised electron source used has been described elsewhere[6]. Briefly, spin-orientated helium (2^3S) metastable atoms are produced by optical pumping in a flowing helium afterglow. Electrons generated in chemi-ionisation reactions involving those metastable atoms and a reactant gas are polarised due to spin conservation[7]. The direction of the electron spin polarisation is easily reversed, without changing the beam trajectory, by reversing the sense of the circularly polarised optical pumping light. The electrons are extracted from the afterglow and formed into a collimated beam by a series of electrostatic lenses. The polarisation of the output beam is determined by measuring the Mott scattering asymmetry when the beam is scattered from a thin gold foil biased at 120 kV (for review see ref. 8). The electrons extracted from the afterglow are polarised transversely as this is convenient for Mott polarisation analysis. A Wein filter[9] located in the beam line is used to rotate the electron spins to obtain the beam of longitudinally polarised electrons required for sample bombardment.

Solid DL-leucine samples (0.6–2.5 mg) were mounted for irradiation on a thin sheet of aluminium foil backed by a layer of scintillation plastic and biased at 120 kV. Samples were held in place either by an extremely thin collodion film (1–16) or, as used by Bonner *et al.*[4,5], in a collodion matrix (17–27). Samples were irradiated with the beam polarised with electron spins parallel and antiparallel to their momentum vectors for target thickness ranging from 8.5 to 40 mg cm^{-2}. Combinations of electron beam current and irradiation times were varied to obtain sample decomposition (as measured by the enantiomeric marker technique[10]) of 35–80%. Although the electron source

used can produce microampere beam currents, we kept currents low to prevent heating of the sample. Despite the wide range of current densities (24–1,110 nA cm^{-2}) no significant variation was observed in the decomposition rate (0.016 mg nA^{-1} h^{-1}), which compared favourably with that of Bonner *et al.*[4,5] (0.015 mg nA^{-1} h^{-1}).

After irradiation, samples were dissolved in 3 M HCl in 2-propanol (2 ml) and maintained at 100° C for 3 h. After solvent evaporation, the resulting 2-propyl esters were treated overnight at room temperature with a 1:1 mixture of trifluoroacetic anhydride and methylene chloride (2 ml). The enantiomeric composition of the resulting *N*-trifluoroacetyl 2-propyl esters was determined by gas-liquid chromatography (GLC)[11] on a column (2.4 m × 2 mm) of SP-300 (5% *N*-lauroyl-L-valyl-*tert*-butylamide on Supelcoport; 100–120 mesh) using a Hewlett-Packard model 402 unit coupled to a Hewlett-Packard model 3370B digital electronic integrator. The precision and sensitivity of the method were confirmed using leucine of known enantiomeric composition processed in a manner identical to the irradiated samples. With 49.5% D-enantiomer our technique measured 49.56 ± 0.1% (5 analyses); with 50.5% D-enantiomer it measured 50.54 ± 0.08 (7 analyses).

Each irradiated sample of DL-leucine provided sufficient material for several determinations of enantiomeric composition. Before each determination either a sample irradiated with unpolarised electrons or a non-irradiated sample was analysed as a control to identify instrumental difficulties. To preclude bias GLC was carried out with the sense of polarisation of the bombarding electrons concealed.

As Table 1 shows, in spite of the wide range of experimental parameters investigated and attempts (samples 23–27) to duplicate as closely as possible the conditions reported by Bonner *et al.*[4], we observed no asymmetric decomposition of DL-leucine by longitudinally polarised electrons. Indeed we observed no single case of preferential decomposition of one of the enantiomers of DL-leucine on irradiation with polarised electrons.

We thank A. R. Harrison for technical assistance. This investigation was supported in part by the NIH (HL-15376), the Department of Energy (Office of Basic Energy Sciences) and the Robert A. Welch Foundation (C-583 and C-704).

REPLY—We are indebted to Drs Walters and Hodge for making available to us an earlier version of the above manuscript in which only the first 22 experiments were reported. At our suggestion that these experiments were not comparable to ours due to the much higher current densities used, they undertook experiments 23–27, where the experimental parameters were apparently much closer to those we used. It is therefore particularly puzzling to us that these last five experiments also failed to show any asymmetric degradation.

In our linear accelerator irradiations we also occasionally (in about one-third of our experiments) observed no asymmetric degradation whatsoever. When an asymmetric effect was observed, however, it was consistently in one direction for AP electrons (three experiments; 43 GLC analyses) and in the opposite direction for P electron (three experiments; 66 GLC analyses), with statistical significance (*t* test) at the 99.9+% confidence level. Clearly, there are unknown operational parameters over which we, at least, had incomplete control in our experiments.

Since the initial publication of our positive results we have reported[1,2] the discovery of the racemisation of amino acids by ionising radiation. It seems likely that such radioracemisation must also compete with asymmetric degradation[2] in irradiation experiments such as ours and those of Hodge *et al.*, whether because of the electrons themselves or their bremsstrahlung. Could it be that unknown experimental parameters might tip the balance between a slight asymmetric bias in such irradiations, or (with overriding radioracemisation) none at all? Future experiments may shed light on this or other possible reasons for the unexplained discrepancies in our results and those of Hodge *et al.*

Errata

In the letter 'Calcium conductance of acetylcholine-induced endplate channels' by P. D. Bregestovski, R. Miledi and I. Parker, *Nature* **279**, 638–639, the greek letter tau (τ) was omitted from six places in the text. These are: para 2 line 13; para 6 lines 1, 4, and 6 (twice); para 9 line 4. These errors are corrected in reprints of the article.

In the article 'Morphology and intracortical projections of functionally characterised neurones in the cat visual cortex' by C. D. Gilbert and T. N. Wiesel, *Nature* **280**, 120–125, in para 4 line 8, for diaminobutyric acid read 3,3'-diaminobenzidine.

Corrigendum

Since publication of the letter 'A Morarian age for the "younger Moines" of central and western Scotland' by M. A. J. Piasecki and O. van Breemen, *Nature* **278**, 734–736, the term 'Grampian group' has been changed to 'Grampian Division'. This follows discussions with an IGS working party and others. The term 'Division' is as used by Johnstone *et al. Mem. Am. Ass. Petrol. Geol.* **12**, 159–180 (1969).

matters arising

Mechanisms for radiation-induced shrinkage of voids

EVANS[1] has recently reported on the radiation-induced shrinkage of voids in molybdenum and its alloy TZM (Mo, 0.5% Ti, 0.1% Zr). Electron microscope measurements made on 3-mm disks irradiated in a fast reactor at 450±25 °C reveal that initially produced swelling of 0.57 and 0.34% at a total neutron dose of 3.5×10^{26} m^{-2} equivalent to 17.5 displacements per atom (d.p.a.) reduced on re-irradiation to 0.20 and 0.01% at a neutron dose of 8×10^{26} m^{-2} or 40 d.p.a. in molybdenum and TZM respectively. A related though opposite behaviour is found in the vacancy type loop structure, typically 5 nm in diameter, whose concentration increased to 6×10^{22} m^{-3} and 1.3×10^{23} m^{-3} at the highest dose level in molybdenum and TZM respectively.

Three mechanisms can give rise to negative swelling rates. First, solute atom segregation at the void surface considered by Marwick[2] which makes the voids biased against vacancies, a possibility discussed by Evans. Second, shrinkage due to thermal emission from voids having a radius less than a critical value[3-6], a mechanism which requires high temperatures and is unlikely to be important in the present context. The third mechanism[5,6], which is applicable at relatively low temperatures of 450 °C and in conditions where vacancy loops are produced, seems to be pertinent for the observations reported for molybdenum and TZM. The trapping of a fraction ε of the radiation-produced vacancies as vacancy loops or as impurities would require that a certain minimum dislocation density ρ_{crit} should develop so that the bias Z_i would allow a sufficient number of vacancies to go to neutral sinks like voids. An expression for ρ_{crit} involving the recombination parameter α, dose rate K and vacancy and interstitial diffusion constants D_V and D_I respectively can be obtained within the framework of the BEK model[7]. The voids will therefore shrink if the total dislocation density due to network and loop dislocation is less than[5,6]

$$\rho_{crit} = (\alpha K/D_V D_I)^{1/2}\varepsilon/(Z_i - 1)$$

The high vacancy migration energy of about[8] 2.0 eV for molybdenum will make D_V small and ρ_{crit} large at low temperatures. Though accurate values of the parameters are not known an estimate using $\alpha/D_I = 10^{20}$ m^{-2}, $K = 10^{-6}$ d.p.a. s^{-1} and $\varepsilon \sim (Z_i - 1) \simeq 0.05$ would give ρ_{crit} in the range 10^{15}–10^{16} m^{-2}. This compares very favourably with the observed vacancy loop densities of 9×10^{14} m^{-2} and 2×10^{15} m^{-2} for molybdenum and TZM respectively calculated from the loop size and concentration values reported. The mechanism therefore seems to be relevant for explaining the radiation-induced shrinkage of voids observed by Evans. The reason that the voids should initially grow at these temperatures and dislocation density values needs careful examination and explanation.

EVANS REPLIES—Krishan and Nandedkar correctly point out that negative swelling rates can arise in a situation where a fraction of the radiation-produced vacancies are effectively removed from the system in the form of vacancy loops. Their expression showing the importance of dislocation density is for the mutual recombination dominant regime. For situations where recombination can be ignored but where thermal emission of vacancies from the loops is still negligible it is easy to show that the condition for void shrinkage is given by $\varepsilon > (Z_i - 1).(Z_i + y)^{-1}$, where Z_i is the bias and y is the ratio of void sink strength to dislocation sink strength. This expression may be more appropriate to the molybdenum case if a vacancy migration energy of 1.3 eV (ref. 1) is accepted.

To apply the mechanism suggested by Krishan and Nandedkar to my void shrinkage results[2] one must, as they point out, explain the growth of voids in the earlier stages of irradiation. In theory this is not too difficult: if one considers the expression above, an initial high dislocation density (and low y) could allow growth of voids. If the dislocation density remains constant the associated increase in y actually leads to a novel saturation condition for swelling but a subsequent drop in dislocation density would lead to the required void shrinkage. However, this picture is too inconsistent with experimental observations to be seriously considered for the molybdenum situation. One example from the void shrinkage results is the simultaneous large increase in dislocation density contrary to the requirements above, but more generally there is the problem of void growth in molybdenum at temperatures down to 330 °C (ref. 3) ($\sim 0.21 T_m$) even when the void sink strength is dominant ($y \sim 10$), and where the Krishan and Nandedkar assumption $\varepsilon(Z_i - 1)^{-1} \sim 1$ would imply negative swelling rates. The only easy way out of this dilemma is to accept that in molybdenum $\varepsilon(Z_i - 1)^{-1} \ll 0.1$, and in contrast to materials such as 316 stainless steel[4,5], assume that the vacancy loops play a negligible part in swelling processes below the $0.3T_m$ threshold. The differences between cascade collapse behaviour in molybdenum and f.c.c. metals during ion bombardment[6] apparently support this viewpoint.

The suggestions of Krishan and Nandedkar may have applications elsewhere, for example, in a thermal cycling situation ((A. J. E. Foreman, personal communication) but cannot easily explain the molybdenum and TZM results. I still feel that the explanation already provided[3,7]—where the segregation of a transmutation impurity (probably technetium) to void surfaces imposes an effective bias on the voids simply by having a low exchange probability for a vacancy—fits the experimental facts reasonably well. Note that this explanation does not depend on the reverse Kirkendall flux that Marwick[8] has suggested for concentrated alloys. However, it does closely fit the surface energy barrier model recently suggested by Fikus and Johnson[9].

Possible Sun–weather correlation

AS I have recently published[1] a re-examination of some of Xanthakis' work[2], in which he claimed remarkably high correlations between solar activity and an index of zonal precipitation (for example, $r = +0.77$ in the zone 70°–80° N and $r = -0.71$ for 60°–70° N), I feel I should comment on the recent exchange between Xanthakis and Gerety[3,4].

My re-examination was prompted by the unusually high correlations claimed, the questionable discussion by Xanthakis of 'X-wise distributions'[5] and, more particularly, by the arbitrariness of the derivation of zonal mean $R - R_0$ values. Xanthakis defined $R - R_0$ for each year and station as the actual total precipitation, R, at that station in that year minus the lowest annual precipitation, R_0, reported for that same station over all the years considered. In the calculation of the zonal means Xanthakis averages together stations having very different mean $R - R_0$ values, with no attempt at normalisation (apart from assigning almost arbitrary R_0 values). Furthermore the stations come in or drop out in random fashion according to whether records are available. Thus, even if a perfect correlation between $R - R_0$ values and solar activity existed at each station (which is certainly not the case), the averaging process would be expected to inject discontinuities whenever a station record began or ended. In this respect Xanthakis' method should lead to poor correlations. This makes the claimed high correlations even more remarkable, and indeed puzzling.

The data for 70°–80° N were re-evaluated because that zone contains the least data, Xanthakis published a full tabulation of his data for that zone[2], and his result for that zone was an apparently highly significant correlation ($r = +0.77$) which did not change sign. Like Gerety *et al.*[6] I found that Xanthakis had used only part of the available data, and my analysis using additional data does not support the claimed highly significant correlation. I obtain a correlation of +0.38 which, considering that the data have been smoothed, is barely significant at the 95% confidence level. Xanthakis rightly points out that a different data sample will lead to a different result. However, the great reduction in the observed correlation using the larger sample certainly throws into question the significance of Xanthakis' result.

More importantly, unlike Gerety *et al.*, I chose only to use data as described by Xanthakis, who stated (or certainly implied) that he used all the available data published in *World Weather Records*[7] except that "only stations with more or less extensive series of precipitation data have been considered"[2]. An examination of his Table 2*a* shows that he used stations with as little as 6 years (Ingoy) or 8 years (Myggbukta) of data.

Examination of *World Weather Records* reveals a complete set of data for Isfjord Radio, Spitsbergen for 1912–24, which Xanthakis omitted even though this meant that for 1912–21 his 'zonal mean' was based on only one station. For the interval 1951–60 there are data for five additional stations—Isachsen (10 yr), Sachs Harbour (5 yr), Clyde (9 yr), Barter Island (10 yr), Chokurdakli (2 yr), and Vize Island (8 yr). All but Chokurdakli lie between the meridians 156° W through 0° to 80° E as stipulated by Xanthakis.

The issue is thus not whether different samples of stations were used, but rather why Xanthakis used the particular stations (which give such remarkable results) and did not use others which detract from the significance of the results. Furthermore, why was no mention made and no reason given for omission from the zonal mean of apparently good data (available from the same data source) from long-record stations such as Isfjord Radio, Isachsen and Barter Island, when shorter records were used from Ingoy and Myggbukta? Why does the choice of stations for inclusion in the zonal means consistently lead to higher correlations than those found using larger data samples?

In an attempt to answer these questions I have tested for the possibility that the correlation coefficients found by Xanthakis using his samples of stations and those found by using the larger available data samples are drawn from the same population by a random or chance selection of stations. According to Snedecor[8] this is done by applying a Z transform to the correlation coefficients and a Student t test to the difference between the Z values.

Table 1 summarises the results for three latitude belts which have been independently assessed by Pittock[1] and Gerety *et al.*[6], following the procedures outlined by Xanthakis[2]. Assuming N independent data pairs as indicated for each latitude belt, the probability P that each pair of samples of stations is drawn at random from the same population is shown. N has been reduced to allow for the computed autocorrelations in the data (including smoothing) according to the standard formula given by Quenouille[9]. Taken separately, the result for each of the three latitude zones suggests that Xanthakis' selection of stations (a selection which gives apparently significant correlations) was probably not by chance. Combining the results, it seems that the joint probability that Xanthakis' favourable selection was by chance is less than 1 in 30,000.

I am grateful to Dr E. J. Gerety for supplying the results of his computations.

XANTHAKIS REPLIES—Pittock claims that the X-wise distribution of the reported correlations between $R - R_0$ and I_a (ref. 1) is questionable. The same dispute was put forward previously by Roberts[2]. However, in the light of recent analysis by Gerety *et al.*[3] it seems that in the zone 50°–60° N their correlation between $R - R_0$ and I_a has changed sign from negative (1885–1913) to positive (1914–60)[5]. This change of sign of the correlation, which is

Table 1 Correlation coefficients, r, between smoothed $\overline{R - R_0}$ and Xanthakis' solar activity index Ia, for three latitude zones over the years indicated, as obtained by Xanthakis[2] with his selection of stations, and those obtained by Pittock[1] (for 70°–80° N) and Gerety *et al.*[6] (for 60°–70° N and 50°–60° N) using larger available data samples

Zone	Years	r		N	P
		Xanthakis	Larger samples		
70°–80° N	1912–60	+0.77	+0.38	19	~0.07
60°–70° N	1882–1960	−0.71	−0.35	31	~0.05
50°–60° N	1914–65	+0.79	+0.20	21	~0.009

P is the probability that the data samples in each latitude zone are drawn at random from the same population, where N independent data pairs are assumed to exist. N has been reduced to allow for the computed autocorrelations in the data (including smoothing) according to the standard formula given by Quenouille[9].

0028-0836/79/290254—02$01.00
© Macmillan Journals Ltd 1979

also observed at other latitude zones as well[4], is what we have originally called X-wise distribution[1].

The values of R_0, at individual stations, were not assigned "almost arbitrarily" but, as Pittock also mentioned, they refer to the lowest annual precipitation reported for the same station over all the years considered.

Pittock re-examined the results for the latitude belt 70°–80° N which, as he agrees, contain the least data. But this zone was only examined[1] to get a general idea of the behaviour of the quantity $R - R_0$ over the polar regions.

As regards the stations Barter Island (70°08′ N) and Clyde (70°27′ N), which are located at the boundary of the latitude belts 70°–80° N and 60°–70° N, these were grouped with the data of the 60°–70° N belt (see Table 3 of ref. 1) and not in the 70°–80° N, because their $R - R_0$ values are negatively correlated with I_a index, that is, as is the case for the corresponding data of the stations in the belt 60°–70° N. It is obvious that if in the very few stations (1–6) of the zone 70°–80° N, two more stations are added, negatively correlated with I_a, the correlation coefficient will be reduced significantly. Also, as King points out, "Analyses combining data from zones exhibiting opposite solar-cycle effects will inevitably lead to the erroneous conclusion that no solar-cycle effect exists, as will an analysis of rainfall data from regions situated between zones in which the sunspot effect is opposite"[6].

The omission of the stations Isachsen (10 yr), Sachs Harbour (5 yr) and Vize Island (8 yr) during the interval 1951–1960 was considered necessary for homogeneity purposes of the record to avoid an abrupt increase of the number of stations in that period.

With regard to the results of Table 1 in Pittock's analysis, I should note that no selection of stations was made for the zone 50°–60° N, for which all stations published in *World Weather Records* were included in the calculations.

Only in the belt 60°–70° N, 20 Siberian stations (long 65°–170° E) were studied separately, because of the different behaviour of their $R - R_0$ values with respect to the corresponding values of the remaining 20 stations in that zone, as can also be seen in Fig. 5 of ref. 1. This separation in my opinion was necessary.

Finally these research studies have been extended to include all the northern and southern latitude zones more comprehensively[4,7,8].

PITTOCK ADDS—Xanthakis' X-wise distribution is questionable because it involves a post-hoc decision for each data point as to whether a positive or negative correlation is appropriate. This adds an extra degree for each data point and enables any random scatter of data to be turned into an impressive apparent correlation. Results obtained by such a process have no statistical significance.

Xanthakis defined R_0 as the lowest annual precipitation reported at that station over all the years considered, but in fact he rounded off R_0 values to the nearest 100 mm below the lowest annual preciptation for most of the stations, but sometimes to the nearest 100 mm above (for example, Myggbukta and Vardo) and in one case to 300 mm at Jan Mayen where the lowest annual preciptiation was 197 mm in 1926. "Almost arbitrary" seems to be a fair description of this process.

Xanthakis now admits that the stations included in his zonal means were selected on a post-hoc basis according to the signs of their individual correlations of R–R_0 with I_a. This clearly invalidates Xanthakis's claimed levels of statistical significance. As indicated in my discussion of X-wise distributions, any set of random data can be classified into sub-groups on a post-hoc basis so as to give apparently significant correlations within sub-groups.

Xanthakis has still not explained why he omitted from his calculations for the zone 70–80° N the data for Isfjord Radio, Spitsbergen for 1912–24 even though he used data from the same station for 1925–60.

When someone comes up with an *a priori* basis on theoretical grounds for grouping stations or data by area, zone or era, and then shows statistically significant correlations within such previously defined sub-groups, we may get somewhere. Selection of data on an arbitrary post-hoc basis proves nothing.

Use of the solar limb effect to test photon decay and cosmological redshift theories

CRAWFORD[1] suggested photon decay as the result of a gradual energy loss of photons due to their interaction with a curved space-time caused by tidal stresses on the finite spread of the photons. He attempts to explain with his theory the Hubble redshift, the solar limb effect, and the photon decay observed from the Pioneer-6 spacecraft when close to the Sun. The main support for his theory comes from the apparent excellent agreement of the prediction of his theory and the observed solar limb effect. The solar limb effect the systematic shift of the wavelengths solar Fraunhofer lines towards red wh going from the centre to the limb of t Sun after solar rotation effects have be removed. The solar limb effect has be used in many other more or less exo theories involving photon deca cosmological redshifts and so on[2–12]. It therefore of interest to summarise t properties of the limb effect and t compare them, in this instance, with t Crawford theory.

Any theory put forward to explain t limb effect should explain the followin properties. (1) After removal of t Einstein gravitational redshift co responding to 636 m s^{-1}, solar spectr lines show a wavelength shift of Δ to t blue at the disk centre. (2) The magnitud of Δ depends strongly on the strength c the line used[13,14] on the position in the lin at which the shift is measured[15] and on th excitation and ionisation potential of th line[16,17]. For weak lines Δ corresponds t ~400 m s^{-1}; for strong lines to ~0 m s (3) When going from centre to limb th wavelength stays nearly constant until on approaches the limb closely. At 0.2 sola radius from the limb the wavelength start shifting towards the red. The absolut shift reaches 0 m s^{-1} at ~0.02 solar radiu from the limb and shows a slight redshif (~0.1Δ) closer to the limb[11], which prob ably disappears at the limb itself. Thi redshift has been called 'super gravitational redshift'. (4) In sunspots th limb effect is absent ($\Delta = 0$)[18].

It was recently shown[19] that all these properties can be explained qualitatively in terms of so-called convective blue shifts resulting from the bright upward-moving convective elements in the solar atmosphere (granules) contributing more to the average radiation than the dark downward-moving elements. Quantitatively, the calculated convective shifts fall short by a factor 2–3 of the observed ones, but that discrepancy may be caused by an inadequate granulation model based on only partially resolved observations of the solar granulation.

Crawford's theory predicts a redshifting of lines when going from the centre of the Sun to the solar limb corresponding to 911 m s^{-1}, which is independent of line strength and position in the line. The same shift should be present in sunspots. Crawford tests his theory using data obtained for relatively weak lines by Plaskett[20], Adam[21] and Higgs[22] after correction of the observed wavelengths for a postulated average radial flow of matter into the Sun of 360 m s^{-1}. He obtains good agreement between the variation of wavelengths between centre and limb predicted by his theory and the 'corrected' data. Had he used the limb effect in strong lines or in sunspots the agreement would have vanished. Had he not postulated the 360 m s^{-1} inflow, a procedure which in our view has no justification, the agreement

0028–0836/79/290255—02$01.00
© Macmillan Journals Ltd 1979

would also have disappeared. Crawford also predicts a redshift of the solar lines at the solar limb of 911 m s^{-1} in addition to the 636 m s^{-1} Einstein gravitational redshift (1.547 km s^{-1} in total). But observations at the solar limb give a value close (within ~50 m s^{-1}) to the gravitational redshift leaving an order of magnitude disagreement with the Crawford theory.

There is in our view no justification of Crawford's theory in terms of the observations of the solar limb effect. A major part, and possibly all, of the solar limb effect can be explained by simple physical processes in the solar atmosphere involving convective, wave and pressure shifts without taking recourse to any of the many exotic theories proposed. Observational and theoretical studies of the solar limb effect, from the point of view of solar atmospheric dynamics are obviously most important in setting limits to the magnitude of the effect predicted by theories of photon decay.

The problem of thrown string

OUR attention has been drawn to the problem of the thrown string[1,2] by Bass and Bracken[3], who related the probability density of the distance between the ends of the string when in space to the volume of the ellipsoid in which the string must be contained. We[4] have already suggested a modification to this theory in an attempt to explain the experimental results of Synge[2]. However, we have recently reconsidered the problem.

We felt that in order to test the validity of the different possible models, an experimental distribution was required

Table 1 Frequency distributions for $\lambda = D/L$

Interval	Frequency 'springy' string	Frequency flexible string
0.0–0.1	344	379
0.1–0.2	641	763
0.2–0.3	739	884
0.3–0.4	662	654
0.4–0.5	485	428
0.5–0.6	481	284
0.6–0.7	391	199
0.7–0.8	427	131
0.8–0.9	450	119
0.9–1.0	400	49
Total	5,020	3,890

based on a large set of observations. The problem of generating the necessary data was solved by posing the problem of the thrown string to our first year engineering students as an exercise in data collection, descriptive statistics and fitting models to data. Each student had to obtain observations for at least a hundred throws of the string. The students were divided into two groups, one used a rather 'springy' red plastic, waxed, string, the other a flexible white cotton string of the same physical dimensions. All the strings were 54 cm long. The pooled data for each group is given separately in Table 1 and the corresponding histograms are shown in Fig. 1.

The density function proposed by Bass and Bracken is shown in Fig. 1. This shows that the model does not give a realistic description of the physical situation.

Observing the thrown string lying on the table it seemed that the steady motion of a point moving along the string from one end towards the other would be some sort of continuous two-dimensional random walk. The problem is then not unlike that studied by Broadbent and Kendall[5] concerning the wanderings of

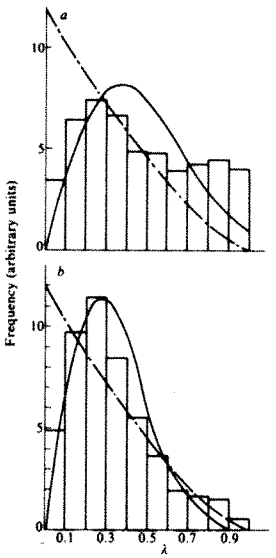

Fig. 1 Histogram and density functions for the 'springy' string (*a*); and for the flexible string (*b*). Bass and Bracken model (dashed line); Random walk model (solid line).

the larvae of the helminth *Trichostrongylus retortaeformis*. They assumed that the orthogonal X and Y components of position were independent random functions of time with zero mean and equal variance. X and Y were then assumed to be Wiener processes. This was not reasonable because it implies that the velocities in the x and y directions would be white noise. Perhaps it would have been more reasonable to have assumed that X and Y were the outputs of identical third order lagging systems excited by separate independent white noises. However, provided the systems were linear, this would not affect the result that after a given time X and Y would have independent normal distributions with zero mean and equal variance.

By analogy, our new hypothesis for the thrown string is that the distance D between the two ends will have probability density

$$f(D) = \frac{D}{\omega L^2} \exp\left(-\frac{D^2}{2\omega L^2}\right)$$

where L is the length of the string and ω is a constant dependent on the nature of the string and the experimental conditions. A similar result was reported by Kingman[6] using a slightly different model.

This density function is compared with the experimental results in Fig. 1 which shows that the proposed model reflects the general nature of the results reasonably well. The discrepancies between the theory and the experiment seem to be due to the lack of ability of the model to describe the upper tail of the distribution. We feel that the large frequencies at the upper tail are primarily a consequence of the impact of the string with the table resulting in a straightening out of the string; the effect is most noticeable in the 'springy' string.

We conclude first that the Bass and Bracken[3] and our previous[4] theories are false in that they are not borne out by experimental results. Second, a good approximation to the distribution is apparently given by the random walk model described above provided the string is not springy. The degree of flexibility of the string may be allowed for by suitable choice of the one parameter in this distribution. More experiments with different non-springy flexible strings are required to verify this second conclusion.

We thank the staff and students who helped with the experiment.

ICE AGES

M

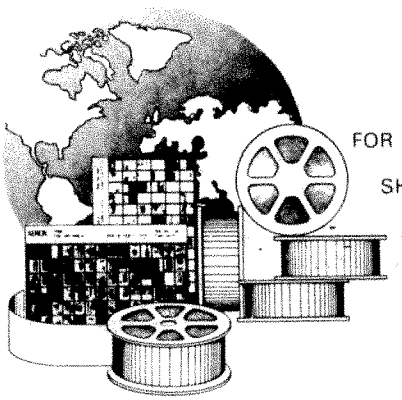
: Solving the Mystery

Professor John Imbrie and Katherine Palmer Imbrie

May 1979 £6.95 224pp 0 333 26767 2 illustrated

Knowledge that the world once endured an ice age has been widespread for more than a century. Indeed, the concept is now so familiar that nearly every winter storm prompts dramatic headlines: Is a new ice age upon us?

This book tackles that burning question and attempts to unfold, for the interested general reader and those with a more academic interest, the entire saga of the Ice Age 'mystery' – why ice ages occurred, what they were like, and when the next one is due.



It is written by one of the principal scientists on the multi-million dollar CLIMAP project which set out to study changes in the climate of the earth over the past 700,000 years. Out of the group's analytical work came an exciting by-product: confirmation of the correctness of one of the several theories of what causes ice ages to occur. The theory that was confirmed, and is now explained along with many others in ICE AGES, is the Milankovitch, or astronomical theory which sees periodical glaciation as the result of three regular movements the earth makes as it travels around the sun: changing ellipticity of the earth's orbit, "wobble" of the earth's axis, and the changing tilt of the earth's axis.

"ICE AGES is fascinating in its scientific interest and also as a detective story. I recommend it to all." Dr. William F. Libby, Nobel Laureate.

Transplantation Antigens — A Study in Serological Data Analysis

by **N.H. Selwood,** *National Tissue Typing Reference Laboratory, Bristol*
and **A.J. Hedges,** *Dept. of Bacteriology, University of Bristol.*

There can be little doubt that the urgent need which arose to resolve the antigen systems of the white blood cell has stimulated an intensity of activity and the generation of data on a scale previously unknown. This book attempts to simplify description of the many new and established methods which have been employed to extract information from basic serological data by dividing them into two main approaches, the statistical and the numerical. The text is directed generally at serologists and, although it inevitably contains some mathematics, these have been kept to a minimum and may be safely overlooked by those whose interest lies in the principles rather than the details. These principles do not relate only to the specialist field of HLA serology but are fundamental to all serological work. It has been the aim of the authors, wherever possible, to refer to basic concepts in order that the questions of applicability should be capable of the widest possible interpretation.

Management of Energy/Environment Systems: Methods and Case Studies

edited by **W.K. Foell,** *Energy Research Center, University of Wisconsin-Madison.*

A book which concentrates on the solution of global energy problems through energy system management at regional and subnational levels. It arises from a joint study by authorities from the east and the west of three regional energy/environment systems with very different political, economic and social frameworks; these are the German Democratic Republic, the Rhône-Alpes region of France and Wisconsin in the USA. This is, therefore, a significant contribution to the management of the energy problems facing most industrialised societies. *(Wiley IIASA International Series on Applied Systems Analysis)*

Biological Indicators of Water Quality

edited by **A. James** and **Lilian Evison,** *Division of Public Health Engineering, Civil Engineering Department, University of Newcastle-upon-Tyne.*

A book on the role of biological indicators in the assessment of water quality. It surveys the quality requirements for the various uses of water, such as supply, fishing, recreation etc. and discusses the various ways in which biological systems of classification have been developed. It covers the whole range from physiological tests to diversity indices and the spectrum of organisms from bacteria to fish. The practical value of the biological methods is stressed and their relation to chemical or physical alternatives. It covers a wide variety of experience from Europe, the United Kingdom and North America.
The book is based on papers given at a conference on the Biological Indicators of Water Quality held in Newcastle.

Progress in Drug Metabolism Vol. 3

edited by **J.W. Bridges,** *Director, Institute of Environmental Health and Safety, University of Surrey,*
and **L.F. Chasseaud,** *Head of Metabolism and Pharmacokinetics, Huntingdon Research Centre.*

This is a review series intended to provide comprehensive, authoritative, readable, up-to-date and critical accounts by experts on the biological fate of a drug or xenobiotic in terms of absorption, distribution, transformation and excretion. The reviews are concerned with newer developments or progress in established areas, or they may retrieve and review the widely disseminated literature on a particular subject with the aim of keeping the reader more easily informed on the many and varied developments in drug metabolism studies.
Further volumes in this series are planned.

Environmental Impact Assessment: Principles and Procedures SCOPE 5 2nd Ed.

by **R.E. Munn,** *Institute for Environmental Studies, University of Toronto.*

As the term is used in this book, environmental impact assessment is an activity designed to identify and predict the impact on the biogeophysical environment and on the health and well-being of humans of legislative proposals, policies, programme, projects, and operational procedures, and to interpret and communicate information about the impacts. Although the institutional procedures to be followed in the assessment process have been formalised in a number of countries, the scientific basis for these assessments is still rather uncertain. The published literature on the subject is scattered through many journals, and has not been evaluated critically in ways that are useful to managers and scientists. The first edition of this book appeared in early 1975. Since then, the number of jurisdictions requiring impact assessment has increased, as well as the literature on assessment methods. For these and other reasons, SCOPE convened a meeting in Toronto in October 1977 to prepare a second edition. A feature of the second edition is an Appendix which gives a selection of engineering references that may be of help when designing to meet environmental standards. *(SCOPE Series)*

July 1979 — 208 pages

Introduction to Marine Pollution Control

by **J. Williams,** *US Naval Academy.*

A holistic approach to marine pollution control drawing on research and developments in physics, chemistry, biology, law, and sociology. It emphasizes frequently encountered problems and situations, describes ocean characteristics that influence the spread of pollution, and offers insights into the nature of pollution, the origin of marine pollutants, and both chronic and acute effects. *(Ocean Engineering Series)*

A physicist who enjoys it

Rudolph Peierls

What Little I Remember. By Otto R. Frisch. Pp.219. (Cambridge University Press: Cambridge, 1979.) £9.50

MOST of nuclear physics has today become "big science", requiring large and expensive accelerators, with complex detection equipment and computers, used by large teams of research workers. Its senior practitioners have to spend much of their time and their energy on administration and organisation. This image of the new scientist does not fit Otto Robert Frisch at all. His very readable reminiscences are those of an individualist, at his best when working and thinking on this own, or with perhaps one close collaborator.

This characteristic comes out very clearly, together with the basic happiness of a man who enjoys what he is doing. Scientists tend to be driven by a variety of motives including, to varying degrees, ambition, a sense of duty to the community, curiosity about nature and its laws, and enjoyment in the design and execution of experiments. All these no doubt have some reality for Frisch, but the pleasure of doing what he does is clearly dominant. Ambition is the least of his concerns.

All this goes for his many other interests. Besides being an outstanding experimenter, with a flair for the simple and decisive experiment, he has many other interests and talents. This breadth probably owes much to his background. He grew up in Vienna, in a family belonging to the cultural tradition of early twentieth-century Vienna. His aunt, the famous nuclear physicist Lise Meitner, was his mentor in much besides physics. Next to physics his strongest line is music. He is a pianist of near-professional standard, and his hearing has absolute pitch. But here again he is less concerned with demonstrating his brilliance at the piano than in the pleasure of making music, and he can enjoy playing with others who may be much below his level in skill, as long as they share his love for music and his pleasure in making it.

He also likes drawing, and after every meeting the papers in front of him are covered with portraits or caricatures. Some of these are reproduced in the book. They are all recognisable likeness, and some bring out the personality of the subject excellently. His drawing is not of the standard of his music or his physics, but his enjoyment in the activity is again evident.

Presumably the drawings reproduced in the book are the most successful ones of many. The written characterisations of people, which, in his preface, he compares with the pencil sketches, also vary very much in depth. Niels Bohr and Lise Meitner come very much alive, as does George Placzek, with whom Frisch worked much in Copenhagen. But very little emerges of Chadwick, with whom he was closely associated in Liverpool and later in Los Alamos, beyond an account of their first encounter; and of some other colourful personalities there are only pale shadows.

George Placzek (1905-1955)

Sketch by O. R. Frisch

As a physicist, Frisch studied in the University of Vienna, where he received his PhD (he does not mention the subject of his thesis). After a year in a small firm making scientific instruments he was offered a position in the Physikalisch-Technische Reichsanstalt in Berlin, and after three years moved to Hamburg to work under Otto Stern, the authority on atomic beam research. That much migration was normal at a time when modern physicists formed a close-knit but widely-spread family.

But in 1933, when Hitler came to power, he had to be dismissed from his post as a "non-Aryan", and there followed the typical odyssey of a displaced academic of the time. A year at Birkbeck College in London under Blackett gave him the first acquaintance with life in England. This was the time when artificial radioactivity was discovered, and Frisch made his first venture into nuclear physics: he invented a clever device to observe very short-lived activities, and was able to discover new species of radioactive nuclei. He stayed in London only a year, and was then invited to Bohr's Institute in Copenhagen, where he remained until 1939.

This was a period of great excitement in nuclear physics. Fermi had started using the newly discovered neutron as a probe for studying nuclei, and neutron physics became one of the major subjects in many laboratories, including Copenhagen. Frisch became involved in this work, originally because he had a well-running counter suitable for detecting the activities produced by neutron bombardment. He describes the way the work was done, including the preparation of neutron sources by mixing radium and beryllium. A

particularly exciting moment was Niels Bohr's first pronouncement of the idea of the compound nucleus, as a comment after a seminar talk which highlighted the difficulties of the then conventional view in accounting for neutron resonances.

Then, in 1938, came the discovery by Hahn and Strassmann that radioactive barium was one of the products of the bombardment of uranium with neutrons. Frisch was visiting Lise Meitner in Sweden when she received the news of Hahn's result, and there is a fascinating account of the discussion which finally led them to realise that the uranium nucleus was undergoing "fission" (a term chosen by Frisch to describe the phenomenon). Before long he was back in Copenhagen and was doing an experiment which verified the suggested explanation.

By this time War was imminent, and Denmark was not a very safe place for a refugee from Hitler, so Frisch moved to Birmingham. He started some experiments relating to the fission problem which was still one of his main interest, but in a department not well equipped for nuclear physics, and with most of its members working on radar, progress was slow. He continued thinking about the implications and possibilities, including nuclear energy. Bohr had shown that a violent explosion was not possible with natural uranium, but Frisch started to question whether the possibility of separating the uranium isotopes in substantial quantities was really ruled out. He and Peierls concluded that a nuclear weapon did not seem to be impossible, and wrote a memorandum which led to an atomic weapons project being started in Britain. From then on most of his effort was devoted to this project. It was an odd situation that he and several others working on one of the most secret military projects were technically enemy aliens, and he tells of a number of ludicrous consequences of this. It soon emerged that he could work more usefully in Liverpool, where Chadwick's laboratory had a small cyclotron and was not preoccupied with other War research. He worked there, through the period of heavy air raids, until 1943, when it was decided to discontinue the British project during War time and send to the United States all those who could be useful to the American atom bomb work. So Frisch went to Los Alamos, and he gives a vivid description of life and work in this odd secret town. Very sensibly he was not attached to one of the large research groups there, but had a roving commission, helping with experimental troubles wherever appropriate.

One of his other accomplishments at Los Alamos was to learn driving, and he tells the story of his first accident, which brought him a broken rib and other minor injuries. He does not seem to remember another accident which became legendary at Los Alamos. Pulling aside to clear another car on a narrow lane without footpath, he knocked over an Army girl. The girl spent a few days in hospital and complained that Frisch had never visited her or shown interest. This was reported to him, and he promptly appeared in hospital, apologising and explaining that he had been concerned. "I enquired of the doctor about about your health and was glad to hear that there was nothing seriously wrong with you, mainly the effect of the fright".

After the War he became head of the Nuclear Physics Division of AERE, Harwell, the new atomic energy laboratory. According to his account of this period, he left the running of the division to his deputy, who enjoyed administration, and continued his individual research. Perhaps his diffident description exaggerates his lack of application to the work of running the division, but it is in character that he was not at his best in this kind of responsibility.

He had been in Harwell less than two years when he was offered the Jacksonian Professorship in Cambridge. The book is exceedingly brief about the 25 years he spent in Cambridge before retiring. He explains in the preface that his memory, like that of many others, is more complete about earlier events than about the more recent ones, and that it is embarrassing to write about people with whom one is still in touch. So the whole period, which includes his marriage and the growth of his two children, gets only a few pages. The story ends with a description of another ingenious device, a machine for measuring and evaluating bubble-chamber tracks, which he designed; he is now a partner in the firm manufacturing this commercially.

Three chapters of the book, Atoms, Nuclei and Research Resumed, contain expositions of parts of modern physics by way of background to the accounts of his own involvement with it. Being a physicist myself, I am not qualified to judge the appropriateness of these pieces. They are written with the clarity and simplicity to be expected from the author of *Meet the Atoms*, yet I wonder whether the reader who does not know the background can

Frisch with Lise Meitner

Avian Orientation and Navigation

Klaus Schmidt-Koenig

July 1979, x + 180pp., £12.50/$26.00 0.12.626550.X

During recent years there has been an explosion of ideas and research in the field of bird orientation and navigation, producing a vast amount of published material which makes a comprehensive account beyond the capacity of a single volume. The present book is more of a summary and review of the literature on all aspects of the subject over the last three decades or so, presenting the current state of knowledge and offering some speculations on future developments. Following a brief introduction to migratory achievements by birds, the main part of the book is devoted to the methodology and results of the experimental attempts to elucidate the mechanisms of orientation involved in bird navigation. In the final section, the hypotheses, theories and concepts that have been advanced to explain the phenomena of migration and navigation are discussed and evaluated on the basis of experimental evidence. The book is unique in its wide and objective coverage of the subject, and will be welcomed both as a reference source and as an introduction to the subject by researchers and students in zoology and animal behaviour, as well as by ornithologists and conservationists.

Climate and Weather in the Tropics

Herbert Riehl

July 1979, xiv + 612pp., £14.80/$31.50 0.12.588180.0

As tropical countries begin to play an important part in world affairs, the effect of tropical climates on agriculture, economic development and even global political relationships is increasingly felt. Therefore it is important that we understand the mechanisms of tropical weather systems and climates. New techniques with satellite and radar are available to help in gaining greater knowledge and international meteorological research has not been slow to exploit the advances made. The publication of these findings has made available much new information. With the current tendency to over-specialize within the broad meteorological spectrum has come a sudden burgeoning of related knowledge. With all this in mind the need arises for an up-to-date overview of tropical climate and weather. This book aims to present clearly and comprehensively the factual bases of the latest advances in tropical meteorology and their interpretation. Satellite and radar information is used extensively in the analysis of convective processes. Ferdinand Baer has contributed an extremely thorough chapter on numerical hurricane prediction; his discussion of the important advances made in the use of computers is applicable outside his particular field.

Society for General Microbiology No. 3

Microbial Polysaccharides and Polysaccharases

edited by R. C. W. Berkeley, G. W. Gooday and D. C. Ellwood

July/August 1979, xvi + 480pp., £16.00/$34.00 0.12.091450.6

Recognition by the Society for General Microbiology of the need to provide a compilation of what is known and what has been achieved, academically and industrially, in the science and applications of microbial polysaccharides was the factor that gave rise to the book. In a sense, it is a combined volume. It brings together papers from two symposia, that of the Society for General Microbiology entitled 'The Microbial Degradation of Polysaccharides' and that of one of its specialist groups, the Microbial Cell Surfaces and Membranes Group, on 'Microbial Extracellular Polysaccharides'. In this way it aims to consolidate discussion of topics from two related areas that have been separately treated in the past, microbial polysaccharides and polysaccharases. It aims, too, to assess current research in these fields and to suggest directions that further research might take in the short and medium term future. Many of the papers presented here are set solidly in a commercial context, emphasising the need to interpret theoretical research in an industrial light. The mixture of contributors is such as to reinforce this approach, comprising chemists, physicists and microbiologists from both academic and industrial backgrounds.

Applications of Graph Theory

edited by R. J. Wilson and L. W. Beineke

July/August 1979, xii + c.424pp., £18.50/$39.00 0.12.757840.4

One of the consequences of the recent rapid expansion of graph theory is that it has become increasingly difficult to determine what is currently known about any particular topic in the field. When it comes to the application of graph theory to the Sciences or Social Sciences this difficulty is compounded by the problem of understanding the language and literature of the area in question. In view of this the editors have collected together a series of expository surveys written by a distinguished group of authors, in the hope that such a collection might prove useful both to professional graph theorists interested in the applications of their subject and to those who may want to learn about the uses of graph theory. Unlike other books on this subject, this volume is written for graph theorists by people actively working in the various fields of its applications such as chemistry, geography, engineering and social sciences.

Integration of Analogue Electronic Circuits

J. Davidse

July/August 1979, x + 276pp., £18.60/$39.50 0.12.204450.9

In present day electronics monolithic technology constitutes a prominent vehicle for circuit implementation. In the context of digital circuitry its proliferation has been widespread. With analogue circuitry the pace of that proliferation has been somewhat slower: understandably so, however, when one considers the range of functions, the spectrum of applications and the variety of specifications characteristic of analogue electronics. The evolution of electronic techniques in this area has reached a point now where knowledge of the principles of monolithic analogue circuit design is indispensable for designers of analogue electronic circuits. That knowledge must also be at least desirable for designers of electronic systems and subsystems in which analogue circuits have applications. With this in mind, the Delft University of Technology has for some years been training students in analogue integrated circuitry. The purpose of the course, and of the book which resulted from it, was to present a comprehensive survey of this area of electronics and its development over the last decade or so.

Secretory Tissues in Plants

A. Fahn

July 1979, x + 302pp., £20.00/$42.00 0.12.247650.6

Secreted substances play an important role in the life of many plants, particularly in the interactions between plants and animals. They have also proved to be of great value to man throughout the ages. The tissues which produce these substances are themselves useful in research as they provide convenient systems for a variety of studies such as biosynthetic processes and short distance transport. Knowledge of their morphology, anatomy and ultrastructure is essential in order to understand how they function and the electron microscope has done much in recent years to further the investigations of the mechanisms of secretion and the relationships between structure and function. This book presents an overall picture of the structure and development of these tissues as determined by both electron and light microscopy studies. It has many illustrations and references. This comprehensive coverage of the subject will interest not only plant anatomists and physiologists but cell biologists, biochemists, endocrinologists and those studying the coevolution of plants and animals.

Advances in Insect Physiology Volume 14

edited by J. E. Treherne, M. J. Berridge and V. B. Wigglesworth

July/August 1979, viii + 442pp., £27.00/$57.00 0.12.024214.1

This highly acclaimed series aims to give a comprehensive survey of selected topics in insect physiology and to relate them to other areas of biological science. The reviews serve as a guide to recently acquired knowledge and also as a stimulus for further advances in the subject. **Contents: John Machin:** Atmospheric water absorption in arthropods. **Franz Englemann:** Insect vitellogen: identification, biosynthesis and role in vitellogenesis. **Arthur M. Jungreis:** Physiology of moulting in insects. **Tom Piek and K. Djie Njio:** Morphology and electrochemistry of insect muscle fibre membrane. **John Palka:** Theories of pattern formation in insect neural development. **Brian W. Staddon:** The scent glands of Heteropters. Subject index. Cumulative list of authors. Cumulative list of chapter titles.

Biomedical Research Applications of Scanning Electron Microscopy Volume 1

edited by G. M. Hodges and R. C. Hallowes

July 1979, x + 364pp., £29.50/$62.00 0.12.351001.5

Although scanning electron microscopy is becoming a routine method in biomedicine, until now there has been no publication dedicated to a discussion of its applications. The purpose of this open-ended series is, then, to review and evaluate these applications integrating current knowledge of structure, composition and function into a comprehensive framework. Each chapter includes a discussion of suitable preparative procedures and co-operative applications of other analytical techniques where appropriate. The scope of the series is such that it should serve as a comprehensive and stimulating guide to people entering the field of scanning electron microscopy as applied to biomedicine and prove an essential reference source for research workers including cell biologists, embryologists, developmental biologists, anatomists, pathologists and immunologists.

Biology of the Reptilia

edited by C. Gans, R. G. Northcutt and P. Ulinski

This widely acclaimed series provides an up-to-date and comprehensive review of the class Reptilia. Volumes 9 and 10 begin a new section in the series, providing the first treatment of the neurobiology of reptiles, a subject that logically ties together reptilian morphology with their physiology and behaviour.

Volume 9 Neurology A

September/October 1979, xvi + 462pp., £30.00/$63.00 0.12.274609.0

Contents: D. Starck: Cranio-cerebral relations in Recent reptiles. **James A. Hopson:** Paleoneurology. **Roland Platel:** Brain weight-body weight relationships. **David G. Senn:** Embryonic development of the central nervous system. **W. B. Quay:** The parietal eye-pineal complex. **Monika von During and Malcolm R. Miller:** Sensory nerve endings of the skin and deeper structures. Author index. Subject index.

Volume 10 Neurology B

October/November 1979, xiv + 376pp., £22.00/$45.00 (approx) 0.12.274610.4

Contents: P. J. Berger and G. Burnstock: Autonomic nervous system. **A. Kusuma, H. J. ten Donkelaar, and R. Nieuwenhuys:** Intrinsic organization of the spinal cord. **William L. R. Cruce:** Spinal cord in lizards. **H. J. ten Donkelaar and R. Nieuwenhuys:** The brain stem. **Martin Ernst Schwab:** Variation in the rhombencephalon. **Andre Parent:** Monaminergic systems of the brain. **M. G. Belekhova:** Neurophysiology of the forebrain. Author index. Subject index.

Food Science and Technology: A Series of Monographs

Brewing Science Volume 1

edited by J. R. A. Pollock

July/August 1979, xiv + 580pp., £30.00/$63.50 0.12.561001.7

It is intended that this volume and the subsequent volumes now in preparation should provide a comprehensive account of the present position of brewing science and its development.

Contents include: M. Moll: Analysis and Composition of Barley and Malt. **A. Mcleod:** The Physiology of Malting. **M. Verzele:** The Chemistry of Hops. **M. Moll:** Water in Malting and Brewing.

The Systematics Association Special Volume No. 12

The Origin of Major Invertebrate Groups

edited by M. R. House

July 1979, x + 516pp., £32.50/$68.50 0.12.357450.1

Two papers give a background setting to the early radiation of the Invertebrata; two more present a review of protozoan and metazoan radiation. Other contributors provide an analysis of the early evolution in invertebrate groups which include the Coelenterata, Bryozoa, Brachiopoda, Echinodermata, Graptolithina and possible early Chordata. In some cases several authors contribute to different aspects of radiation, for example that of Arthropoda. For the Mollusca there are four contributions from zoologists and paleontologists. A final chapter combines points taken from a recording of the meetings with written contributions to reflect the informed and lively exchanges that took place.

Organometallic Chemistry: A series of Monographs

Transition Metal Complexes of Cyclic Polyolefins

G. Deganello

August 1979, viii + 480pp., £34.50/$72.50 0.12.207950.7

The book is divided into five chapters dealing with metal complexes of cycloheptatriene, cyclotatetraene, cyclooctatriene, bicyclo [6.n.0] trienes and other polyolefins but each chapter also describes metal complexes of polyolefins related to these. Each metal or metal group is treated in order of increasing atomic number. The main topics discussed in detail are preparation, spectroscopic characterisation, structure, reactivity, and catalytic activity. Metal complexes of other organic moieties originated by rearrangement of the above polyolefins are also included. Particular emphasis is placed on NMR investigations and an appendix is added on the mechanistic aspects of the fluxional behaviour manifested in solution by several dimetal hexacarbonyl polyolefin complexes, studied by ^{13}C NMR spectroscopy.

Hormones in Blood 3rd Edition

edited by C. H. Gray and V. H. T. James

The three volumes provide a unique and definitive reference work which will be invaluable not only to the general scientific and medical reader needing to up-date his knowledge, but also to the specialist interested in the biochemical, physiological and clinical aspects of endocrinology.

Volume 1

July 1979, xx + 704pp. £37.50/$79.00 0.12.296201.X

Contents: D. R. Bangham: Foreword: standards for hormones. **A. Arimura and A. V. Schally:** Hypothalamic releasing and inhibiting hormones and factors. **U. A. Parman:** Insulin. **P. J. Lefebvre and A. S. Luyckx:** Glucagon. **P. H. Sonksen and T. E. T. West:** Growth hormone. **K. Hall and L. Fryklund:** Somatomedins. **S. Franks:** Prolactin. **T. Chard:** Human placental lactogen. **K. D. Bagshawe, F. Searle and M. Wass:** Human chorionic gonadotrophin. **W. R. Butt:** Gonadotrophins. **P. Mary Cotes and D. E. Gueret Wardle:** Erythropoietin. **P. G. Condliffe and B. D. Weintraub:** Pituitary thyroid-stimulating hormone and other thyroid-stimulating substances. **J. Robbins and J. E. Rall:** The iodine-containing hormones.

Volume 2

July/August 1979, c. 600pp., £27.50/$58.50 0.12.296202.8

Contents: D. R. Bangham: Foreword: standards for hormones. **G. N. Hendy, S. E. Papapoulos, I. G. Lewin and J. L. H. O'Riordan:** Parathyroid hormone. **S. E. Papapoulos, I. G. Lewin, T. L. Clemens, G. N. Hendy and J. L. H. O'Riordan:** Vitamin D. **L. J. Deftos:** Calcitonin. **B. A. Callingham and M. A. Barrand:** The catecholamines: adrenaline, noradrenaline and dopamine. **G. A. Smythe:** Serotonin. **J. A. Salmon and R. J. Flower:** Prostaglandins and related compounds. **S. R. Bloom:** Gastro-intestinal hormones I: pancreatic polypeptide, motilin, gastric inhibitory peptide, neurotensin, enteroglucagon and others. **G. J. Dockray:** Gastro-intestinal hormones II: gastrin, cholecystokinin and secretin. **C. R. W. Edwards:** Oxytocin. **C. R. W. Edwards:** Vasopressin.

Volume 3

August/September 1979, c. 700pp., £35.00/$78.00 (approx) 0.12.296203.6

Contents: D. R. Bangham: Foreword: standards for hormones. **J. Landon:** Non-isotopic immunoassay. **C. K. Lim:** High performance liquid chromatography. **K. Setchell:** Gas-liquid mass spectrometry. **Lesley H. Rees, P. J. Lowry and I. Hughes:** Adrenocorticotrophin and melanotrophin. **Diana Riad-Fahmy and G. Read:** The cortico-steroids. **M. J. Reed and M. A. F. Murray:** The oestrogens. **A. Vermeulen:** The androgens. **H. J. van de Molen:** Progesterone I. Metabolic aspects. **K. Fotherby:** Progesterone II. Clinical aspects. **J. P. Coghlan, B. Scoggins and M. Wintour:** Aldosterone. **Brenda J. Leckie, J. A. Miller, J. J. Morton and P. F. Semple:** The renin angiotensin system. **R. Greene:** Endocrinology in clinical medicine.

Now available ON SUBSCRIPTION

BULLETIN OF THE BRITISH MUSEUM (NATURAL HISTORY)

Published in five Series, ZOOLOGY, ENTOMOLOGY, BOTANY, GEOLOGY and HISTORICAL the Bulletin differs from most serials in that each part is virtually a monograph and complete in itself, the occasional very short papers being collected together into a batch under 'Miscellanea' rather than being bound in with longer works. Papers in the BULLETIN are primarily the results of research carried out by the scientific staff of the Museum, and by specialists from elsewhere, on the unique collections of the Museum, which are constantly increasing. Many of the papers are important works of reference and will remain so for many years to come.

ALL FIVE SERIES ARE NOW AVAILABLE ON SUBSCRIPTION. Each volume consists of some 300 to 400 pages and is priced according to its contents, the parts appearing at irregular intervals as they become ready. As each volume nears completion subscribers are appraised of the contents and price of the next volume and invited to renew their subscriptions. Completion of a volume is not timed to coincide with any calendar period. Subscriptions may be placed for one or more Series.

The subscription system has many advantages. Librarians can now ensure that they receive every issue, sent by accelerated surface mail, soon after its publication and will know well in advance the cost of the next volume and so can budget ahead. Subscriptions placed directly with the Museum earn a discount of 10 per cent.

Separate parts of the Bulletin are available, priced individually and a complete catalogue may be had free of charge.

Orders and enquiries for the Bulletin and other Museum publications should be addressed to:

REGULATION OF FERTILITY

INSERM Vol. 83 – 432 pages / 60 Francs

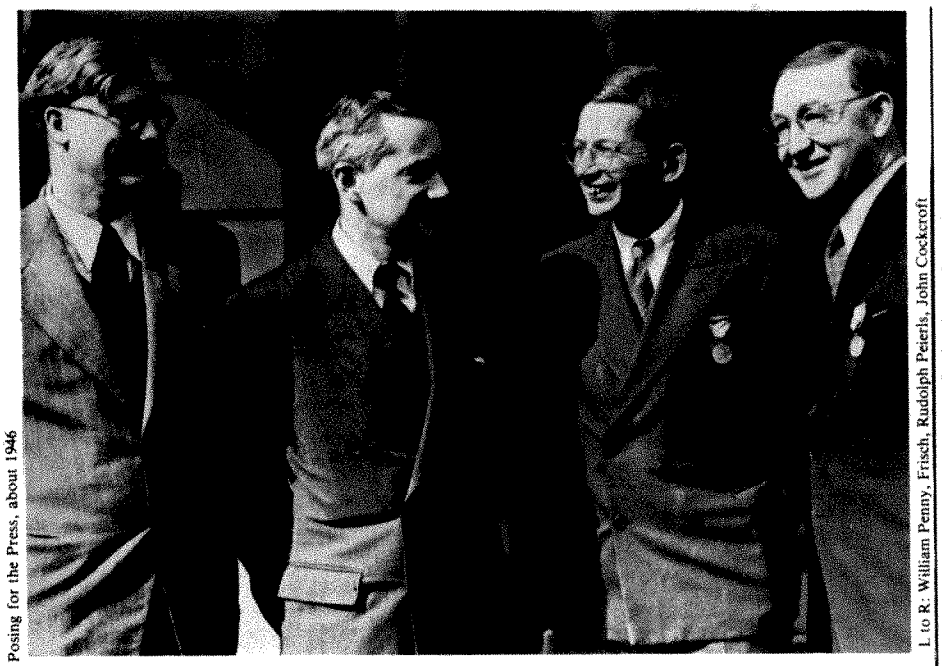
Proceedings of the international symposium organised in March 1979 by the Conseil Supérieur de l'Information sexuelle, de la Régulation des Naissances et de l'Education familiale, sponsored by the INSERM and the INED.

25 papers: 15 in French with English summaries, 10 in English, which cover a wide variety of topics:

1° The present state of knowledge on the medical effects of contraception (contraception and vascular risks, contraception and tumors, contraception and subsequent fertility) leading to a more precise definition of the indications and contra-indications of contraceptive prescription;

2° The demographic and psychological consequences of using a contraceptive method;

3° Future prospects provided by fundamental research.



Orders and remittance should be sent to

Posing for the Press, about 1946

L to R: William Penny, Frisch, Rudolph Peierls, John Cockcroft

really assimilate enough information to help him with the biographical chapters which are the real meat of the book, and which seem quite intelligible on their own.

This is a happy book, from which the author's personality and his enjoyment of physics, of music, of life, emerges clearly. It is also a portrait of the pre-War world of physics, of the days of small numbers and small apparatus, of times when a physicist could think of an ingenious experiment today and set it up tomorrow. □

Sir Rudolf Peierls was Professor of Theoretical Physics at the University of Oxford until his retirement in 1974, and was previously Professor of Mathematical Physics at the University of Birmingham from 1937-63.

Gelada baboons

Ecological and Sociological Studies of Gelada Baboons. Edited by M. Kawai. Pp. 344. (S. Karger: Basel, Munchen, Paris and London, 1978). DM148; $74.

In a variety of ways, gelada baboons are one of the most unprimate-like primates: they are almost exclusively terrestrial; they feed extensively on grass; and they aggregate in large herds of unstable membership. Consequently, they are a species which might be expected to shed extensive light on relationships between ecological variables and behaviour and on the functional significance of behavioural differences between primates and ungulates.

The volume recently edited by Kawai provides a broad description of the ranging behaviour, social organisation and feeding ecology of the species in the Gich area of the Simien National Park in Ethiopia, but does little to provide satisfactory explanations of the geladas' many surprising characteristics. Four observers habituated several herds and learnt to recognise all individuals in one of them. As a result, they were able to examine both detailed social relationships among individual members of the harem-groups which aggregate to form herds, and relationships between neighbouring herds.

Twelve chapters, by combinations of the four authors, cover herd dynamics, inter-harem relationships, social behaviour within harems, the development of social behaviour and group structure, reproductive behaviour, communication, ranging behaviour and feeding ecology. Particularly in areas where it concentrates on answering questions rather than broad, quantitative description, the book reveals fascinating insights into the behaviour of the species: its description of herd stability, of grooming relationships within harems and of food intake in relation to abundance, provide novel coverage of important topics.

Sadly, the reader's interest is titillated more often than it is satisfied. Why do females periodically discipline their harem males by chasing them up cliffs? Why do harem masters tolerate the presence of extra males in their harems which, even if they are temporarily inhibited from breeding, are likely to contest their hegemony in future? And why do male geladas not control their females in as chauvinistic a fashion as male hamadryas baboons — which share a similar environment and social system? Attention to specific questions of this kind would have provided the book with a stronger connecting theme and reduced the extent to which it overlaps the previous volume on geladas in the same series.

Food, Energy and Society

David Pimentel and Marcia Pimentel

Resource and Environmental Sciences series

This book examines the relationship between food, energy and society. The authors analyse and compare the ways in which different societies, both 'developed' and 'undeveloped', use different kinds of energy in producing their food. They also investigate the effects of substituting other resources (such as labour or land) for some of this energy, and assess the nutritional quality of a variety of diets.

The aim of this book is to explore the interdependencies of food, energy and their impacts on society. These analyses, it is hoped, will be a basis for planning and implementing policies of individuals and nations as they face the inevitable dilemma of how everyone can be fed, given the limited resources of the earth.

Trace elements in metabolism

Trace Elements and Iron in Human Metabolism. By A.S. Prasad. Pp. 380. (Plenum: New York, 1979). Available in UK, Middle East and Africa from Wiley (Chichester, UK) at £17.50; $35.

IF a monograph is defined as a systematic and exhaustive examination of a particular subject, then this book, contrary to the statement in the Foreward, cannot be so described. It contains information about not only the well-established (chromium, copper, fluorine, iodine, manganese and selenium) and newer (nickel, vanadium, silicon and tin) trace elements, but also magnesium, iron and certain toxic metals. This last section is highly selective in its choice of metals (cadmium, lead and mercury) and seems quite out of place in the present volume; the brief chapters are superficial and contain statements that are either incorrect, or likely to mislead. Thus, for example: "hypertensive subjects have abnormally high concentrations of renal cadmium" (p354); "A similar protective effect of excess zinc against lead toxicity was noted in young horses" (p365); and, "The physiocochemical classification of mercury does not correlate well with its toxic properties" (p371).

Even the review of the field of essential metals is an enormous task for a single author, and although Dr Prasad has produced an informative summary, inevitably many of the recent developments have been omitted. The chapter on chromium (confined essentially to the glucose-tolerance factor), selenium (devoted largely to glutathione peroxidase) and the newer trace elements, for example, contain only 2,2 and 1 reference(s), respectively, to work published later than 1975, whilst in the chapter on iron (a detailed, 60-page, review) 94% of the 428 references are to publications before 1971. Also the references to published work are perhaps inevitably for such a large subject, rather selective. Nevertheless, the book provides a clear account, not by any means exhaustive, of certain aspects of the action of trace elements aiming to link molecular biology, biological and animal experimentation with human nutrition and clinical experience. This is a highly commendable aim and the book can be recommended to provide such a broad view which, if depth is required, will require supplementation with further reading. The individual chapters on copper, iron and zinc, in particular, are extremely thorough and informative.

The very readable text is, in some cases, rather repetitious largely due to the subdivisions in each chapter, such that the experimental work in animals is often separated from observations in man. Furthermore, the considerations of the functions and mechanism of action of the trace elements are somehow diluted by sections on toxicity and therapeutic measures. The book is well produced, but for such a wide general coverage of the subject, a more detailed index might have been an advantage.

With the provisos mentioned above, this book can be recommended for those who wish to quickly obtain a general view of the biology of trace elements with particular reference to man. Contrary to the title, the volume is not restricted to human metabolism, but at least in certain sections also deals extensively with studies in experimental and domestic animals. Thus, it covers much but not all, of the ground already surveyed by Underwood in the fourth edition (1977) of his book *Trace Elements in Human and Animal Nutrition* (Academic; New York, San Francisco and London).

- *Rutherford and Physics at the Turn of the Century*, edited by M. Bunge and W.R. Shea (for review, see *Nature*, **279**, 741; 1979), was published by Neale Watson Academic (New York) and Dawson (Folkestone, UK), and not as stated.

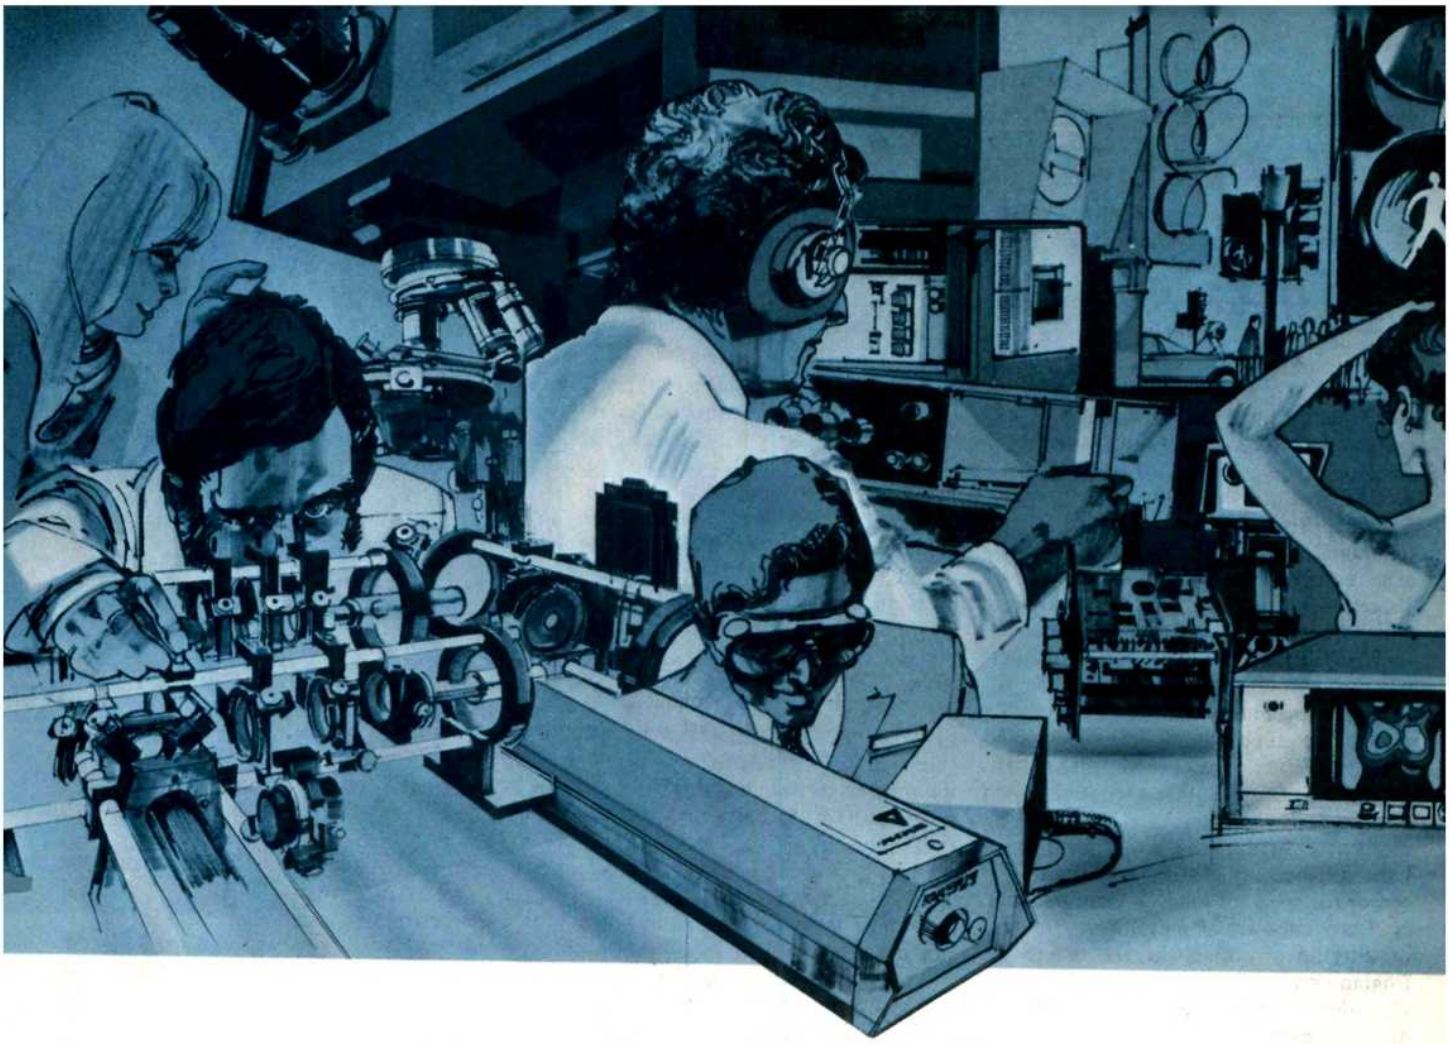
Electromagnetic wave propagation

Methods in Electromagnetic Wave Propagation. By D.S. Jones. Pp. 887. (Clarendon/Oxford University Press: Oxford, 1979.) £22.50.

THE field of electromagnetism has, as the author claims, undergone considerable development in recent years. Motivated by such fields as satellite communications, radar and geophysical prospecting the search for better methods of solution to important problems in the areas of electromagnetic wave propagation and scattering has intensified. Existing classical methods of applied analysis have been extended, complemented or indeed supplanted by new numero/theoretic methods based upon modern applicable mathematics. Professor Jones, himself a leading researcher in the field, is to be congratulated on presenting these methods in a systematic manner and critically reviewing their application.

The book is very large, containing over 800 pages in 9 chapters. The first chapter is introductory and contains the mathematical features used in the remainder of the book. The problems of propagation in waveguides are discussed in chapters 2, 3 and 4. Solutions are found by finite differences (chapter 2) and by variational methods (chapter 4). As these problems can often be reduced to finding eigenvalues of operators, this is described in some detail in chapter 3. The implementation of variational methods to provide numerical bounds on approximate solutions is the main concern of chapter 5.

The advent of the digital computer has transformed the antenna design field and classically 'difficult' problems are now amenable to numerical analysis. Both wire and solid antennas are treated in chapter 6 where integral equations of various types are studied from analytical and numerical points of view. Guidance on methods for dealing with transient phenomena is given in chapter 7.



The most exciting material in the book for the reviewer is in chapter 8 where the geometric theory of diffraction (GTD) is developed from first principles. Very few authoritative accounts of this subject are available and the author has devoted one quarter of his book to it. The use of GTD in the design of reflector antennas has become increasingly important in recent years. Finally the problems of inverse scattering, that is, describing the source knowing its scattered field, is discussed in chapter 9. Nearly 400 references are listed, although few appear for 1977 and none afterwards.

It is perhaps churlish to mention omissions in a book of this length but no space has been found for recent work on general reflector synthesis involving Monge-Ampère equations or the use of complex coordinates and stereographic projection in geometrical optics.

The quality of the material and the clarity of its exposition makes this an important reference book for research workers and lecturers (there are numerous exercises) in the electromagnetic field.

B.S. Westcott

In the high skills of the new engineering technologies you need the resources of Barr & Stroud

We maintain a serious commitment to research, design and development. As a result, our work in all product fields displays innovative and manufacturing quality to the highest degree.

Time and again, you can depend on our long-term expertise to produce solutions for the most complex problems.

In fibre optics, for example, our experience spans the widest possible spectrum of applications – computers, process control, medicine, colour detection, automatic inspection, even traffic signs.

In lasers we design and manufacture some types ourselves. For others, and to give a comprehensive service to the market, we distribute the products of premier US manufacturers.

But in other fields, such as infra-red transmitting materials, we can fairly claim to be the only UK manufacturer whose products are worth consideration.
Our latest developments in these materials, together with a complementary coating facility, enable us to produce components for use in industrial, medical or military systems – to the most exacting specifications.

Similarly, thanks to our success in developing electronics technology, we at Barr and Stroud depend almost exclusively on our own resources. In particular, we have built up impressive expertise in filter requirements that is second to none: whether in standard products or custombuilt service, passive, active or crystal types to a frequency limit of several tens of MHz.

Even in those more traditional areas of optics and precision engineering, where our leadership was originally established, we are continually up-dating our capabilities in order to combine the latest state-of-the-market developments with the most modern engineering techniques.

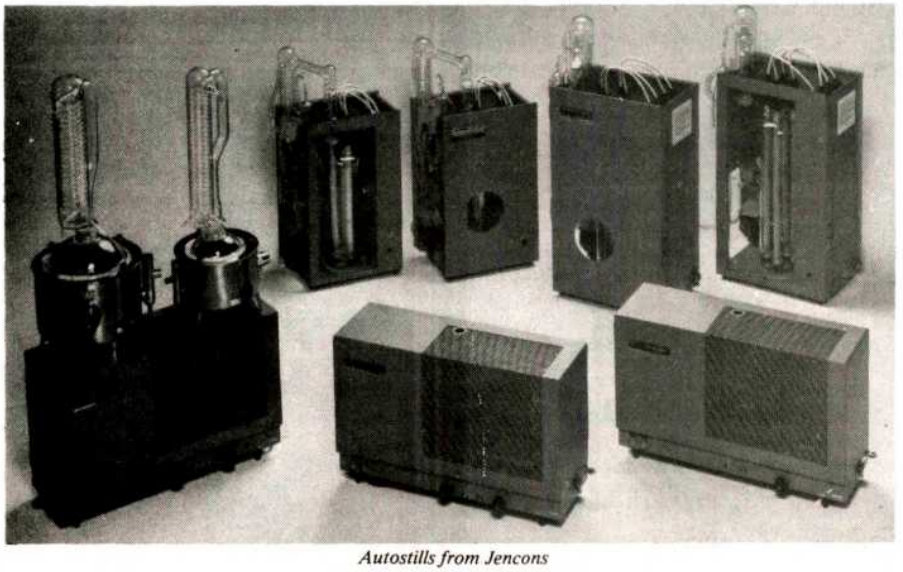
new products for tissue culture

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. For more details use the Reader Enquiry Card bound inside the cover.

A feature on chromatography will appear in the 23 August issue.

BORO LABS



Boro Labs Ltd of Aldermaston have for several years been closely involved in the field of tissue culture as a result of their sole distributorship for the popular Salamander CO_2 incubator. The Salamander incubator is of all stainless steel construction and features a water jacket enclosing five sides of the chamber which ensures superb temperature control and stability. Dual circuit fail-safe thermostats ensure additional protection for valuable specimens. Automatic humidity control is available as an optional exta and the unit can also be supplied with automatic CO_2 changeover unit, and custom built access ports. The CO_2 monitor/controller is a purpose built katherometer unit utilising a thermistor sensor for speed of response and sensitivity. Boro Labs are also major distributors of Sterilin products in the south of England and are able to offer prompt service of this manufacturers wide range of disposable items.

JENCONS

Distilled water of sufficient purity for use with tissue culture is produced by the Autostill distillation unit from Jencons (Scientific) Limited. The Super-Four and Super-Eight models are fitted with special safety featues so that in the case of a water failure the electrics switch off — thus protecting the laboratory against a fire risk. If, however, there should be an electrical failure the water automatically switches off which will safeguard the laboratory against flooding. A further safety device switches off both electrics and water when the distillate reservoir is full. Distillate being drawn off from this reservoir will activate the level control system so that 'automatic top up' is always available. Included in the Jencons distillation range is a 2nd Stager Autostill for connecting to an existing unit to produce double distilled water. The D-Ionstill for distilling your own supply of dionised water and also an inexpensive pair of general purpose type stills which produce a good quality distillate, and are inexpensive to run. Further items of interest to the tissue culture laboratory are the Jencons Accuramatic, Petri dish filler/bottle dispenser. This unit incorporates a simple sterilisable silicone tubing assembly through which liquid is accurately dispensed. The Accuramatic is so designed that when it is not in the dispensing mode the liquid in the delivery reservoir is kept in suspension. the Accuramatic dispenses at the touch of a button 0.4 to 575ml, or automatically with a variable interval between doses. It also has a standard and low speed control to ensure accurate, steady and constant filling of small containers. Also available is a range of suspension culture flasks with impellors and single or double take-off side arms. These flasks are manufactured from borosilicate glass and the larger capacities incorporate baffled sides and double impellor assembly for greater turbulence. The Jencons catalogue describes many other items suitable for tissue culture applications.

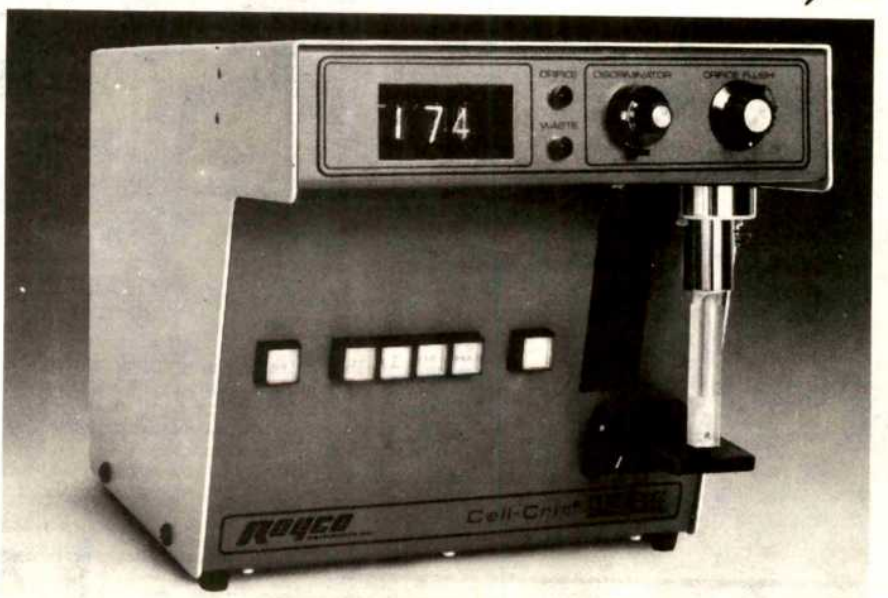
Autostills from Jencons

FLOW LABORATORIES

Flow Laboratories have been involved with tissue culture since its inception in the sixties and the company now supplies cells, growth media, sera and materials and equipment required for tissue culture. More than 180 different cell types are available from Flow Laboratories Ltd, Irvine, Scotland. All cells are grown using Flow Laboratories media, sera and glassware. Each cell line being grown is monitored for the absence of mycoplasma each time it is passaged and antibiotics are not used, to avoid possible formation of L-form bacteria. This also ensures that any contamination is not suppressed and does not remain unnoticed.

All growth media produced by Flow Laboratories are quality controlled using cells produced in house to ensure stringent growth test criteria. Different cell types are, of course, used for different media types. For example, RPMI 1640 medium is used for the growth of lymphocytes and is tested using EB3 cells, a lymphocyte cell line, along with human embryonic cells. These tests are in addition to pre-production checks on chemical quality and water purity, and the testing of the finished product for composition and physical properties.



Sera for tissue culture are submitted to growth tests similar to those used for media, and also to special tests for mycoplasma. Should mycoplasma be found in serum or any other biological material, that material is discarded. All bovine sera are routinely tested for the presence of BVD and other viruses causing cytopathic and haemadsorbing effects and donor sera are tested for the presence of bacteriophage.

Flow Laboratories produces a range of treated plastic labware for cell culture purposes. These plastic products are subjected to a special process to create favourable conditions for cell attachment and growth. Again, quality and performance are strictly monitored by procedures involving growth of cell cultures in these products. The glassware supplied by the company is used for cell culture

If you were designing a tissue cell counter, which features would you want to build in?

- ☐ Automatic Coincidence Correction
- ☐ Variable Linear Threshold
- ☐ Automatic Detergent Rinse
- ☐ Dynamic Size Range $20\mu^3$-$65{,}000\mu^3$
- ☐ Non-Mercury Manometer
- ☐ Unbreakable Aperture Tubes
- ☐ Clog Alarm/Removal Device
- ☐ Lightweight & Compact
- ☐ Superb Accuracy
- ☐ Solid State Electronics
- ☐ Low Price
- ☐ **All of the above**

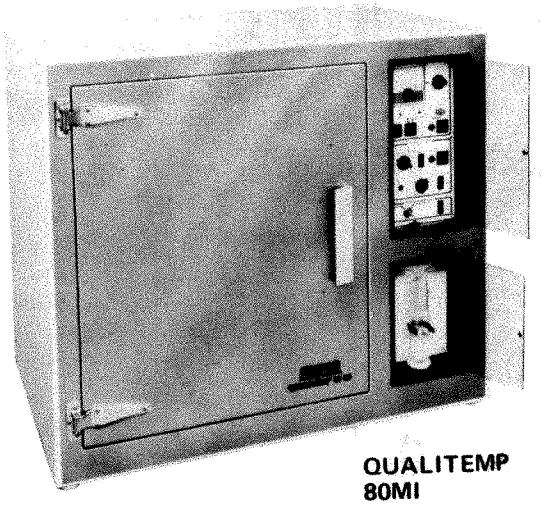
UNITEMP®

LABORATORY INCUBATORS

- **Progressive Styling**
- **3 models available**
- **Sensitive, solid-state control with over-temperature protection**

Designed in consultation with laboratory technicians this new range combines progressive styling with practical efficiency and consistent high performance. It incorporates all the features you have always wanted in an incubator, and is constructed to the high standards of craftsmanship and materials which have long been associated with the Unitemp name.



PERFORMANCE	SMALL MODEL	MEDIUM MODEL	LARGE MODEL
Temperature range	5° above ambient at 100°		
Temperature variation	1.5°C	2°C	2°C
Temperature fluctuation at a point (37°C for 30 min.)	0.25°C	0.25°C	0.25°C
Temperature drift (37°C over 72 hr. 10°C change in ambient)	±1°C	±1°C	±1°C
Recovery time door open (30 sec. from 37°C unloaded)	3 min.	4 min.	5 min.
Thermostat override on over-temperature control	Up to 100°C all models

B & T

QUALITEMP®

CARBON DIOXIDE INCUBATORS

QUALITEMP 80MI

QUALITEMP 80TC

- Very stable temperatures
- High humidity
- Choice of gassing systems
- Stainless steel interiors

A quality range of tissue culture incubators offering a choice of two models: the continuous gassing type 80TC or the monitored injection type 80MI. In the latter case consumption of CO_2 is minimised since gas is only supplied to the incubator when CO_2/Air concentration falls below your pre-set level.
In addition, the Qualitemp 80MI has a key operated switch which automatically raises the internal temperature to 90°C for decontamination.

Full specifications available from

B & T

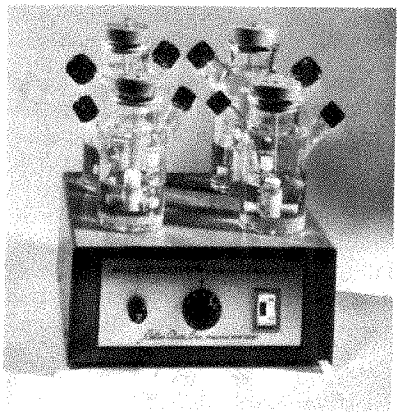
The First Choice

Circle No. 18 on Reader Enquiry Card.

orders and many of the plastic products are used in quality control procedures for cells, media and sera.

Flow Laboratories automatic CO_2 incubators are of a high specification, are water-jacketed to ensure stability of temperature, and have a totally automatic CO_2 control system to ensure economic use of CO_2. High quality stainless steel construction is used throughout. The CO_2 concentration range is 2–20% and variation at 5% is ±0.2%. The temperature range is from 4°C above ambient to 80°C with a control variation of ±0.1% at 37°C.



A range of laminar flow equipment has also been developed. The options include horizontal flow, vertical flow and recirculating models. All units are of rugged, all-metal construction and are fitted with HEPA filters with an efficiency beter than 99.99% for particles of 0.3μm or greater.

Superbead microcarriers are a new development in cell culture technology. They provide a large surface area for cell growth when suspended in a liquid culture medium, making it possible to grow large numbers of anchorage dependent cells in pseudo suspension with all the attendant savings in glassware, medium and time. Flow Laboratories, in conjunction with MIT, have developed a microcarrier suitable for the attachment and growth of the maximum number of cell types.

A.R. HORWELL

With the ever-increasing interest in tissue culture, Arnold R. Horwell Ltd of London are now able to supply products from some of the leading manufacturers of the specialised equipment used in this field. Two ranges of disposable tissue culture equipment are available from Horwells, Sterilin and Costar. Costar have recently added a new triangular culture flask to their range; the design of the flask makes it easier to insert pipettes for feeding or fluid changes. Costar Stripettes are disposable sterile pipettes made from polystyrene which have a unique colour band running the length of the pipette; this band is magnified by the liquid contained in the pipette making it easier to observe the meniscus level. Existing Costar products include a range of traditionally-shaped culture flasks, multi-well cluster plates, as well as culture dishes. The Bellco Glass range of glassware for tissue culture includes two types of hanging-bar spinner flasks — one type with central rubber stoppers, and the other with a central plastic screw cap; sizes are from 25ml to 36 litres. A complimentary range of non-heating magnetic stirrers for the above flasks is available. These stirrers are designed for continuous operation, without the possibility of transferring heat to the culture mechanism; units can be supplied with one, two, four or nine positions for flasks. For continuous culture techniques, Bellco produce the Autoharvester. This is based on their cell production roller apparatus, and has facilities for adding and collecting media at pre-set intervals over as long a period as required.

At Last! A Reliable Incubator Under $100

Designed for Aerobic or Anaerobic Tissue Culture Experiments

Shown at ASM and FASEB Meetings

With this Modular Incubator Chamber[1] you no longer have to worry about the inherent variability (due to CO_2, temperature and humidity fluctuations) of present day continuous flow and anaerobic incubators.

Simply place your experiment into the sealed chamber, purge the system with the required gas mixture and set in a controlled temperature environment.

Because each chamber is an isolated system you now have the flexibility to design experiments you previously thought were impractical or too expensive.

Chamber and tray components are made from rugged, non-toxic, uv-resistant polycarbonate.

Multi-purpose trays conveniently hold petri dishes, test tubes, T.C. flasks, microtest plates, etc.

Chambers can be stacked and interlocked for agitation or storage.

And now for the best part. The price of the chamber with 3 trays is only $95.[2] To order or for further information phone or write Billups-Rothenberg, Inc., Dept. N-1, P.O. Box 977, Del Mar, CA 92014 USA (714) 755-3309.

FROST INSTRUMENTS

Frost Instruments of Wokingham, UK, supply a varied range of equipment for tissue culture which includes a range of incubators to suit all requirements. A popular model is the Grant CO_2 incubator, which features a stainless steel interior with horizontal air flow system, and extremely sensitive control for both temperature and humidity. The inner chamber is of stainless steel and has positions for 11 shelves. The unit is guaranteed for 3 years.

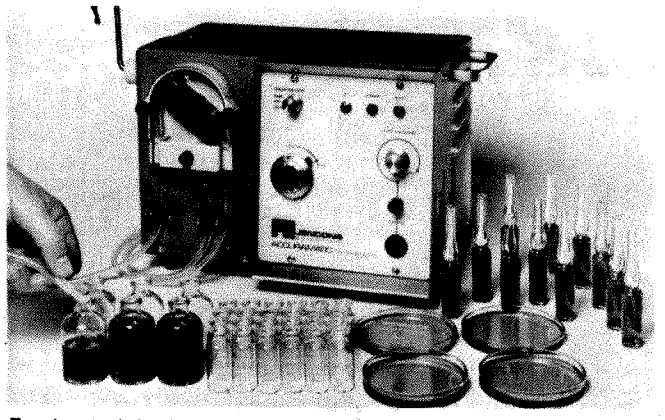
AMERICAN OPTICAL CORPORATION

The Scientific Instrument Division of American Optical Corporation have introduced the Biostar, a new inverted biological microscope which is readily adaptable to diverse applications and varied specimen preparation techniques. Each component of the instrument is designed for optimum performance in the inverted mode. The proven infinity corrected optical system is introduced to inverted microscopy for the first time. This system provides exceptional flexibility and better optical correction for lateral colour, astigmatism and curvature of field. The solid state illumination system of the Biostar is unique to this type of instrument, providing exceptional illumination



The American Optical Biostar inverted microscope

by means of a quick-change 20-W tungsten halogen lamp, a built-in field diaphragm, and a built-in dual view/multi-view adapter. To avoid light loss between illuminator and condenser, a highly corrected focusing system is used. An oblique illumination system is available for flask microscopy techniques. A wide selection of planachromatic and achromatic objectives (brightfield and phase/dark contrast) is available. The large 8″ × 10″ stage is solidly attached to the wide, sturdy stand.

COLLABORATIVE RESEARCH

Collaborative Research have added endothelial cell growth supplement (CR-ECGS) to their expanding range of *in vitro* growth factors. This powerful adjunct for cell culture makes it feasible, for the first time, to grow and maintain human vascular endothelial cells at low cell densities in monolayer culture. When added at the recommended concentration to serum-containing medium, CR-ECGS promotes a six- to tenfold proliferation of human vascular endothelial cells over a 10-day period. CR-ECGS also supports the repeated passaging of established cultures. Collaborative Research human fibronectin (CR-HFN) is isolated from human fibrinogen. Human fibronectin adsorbs to the surfaces of any glass or plastic culture vessel or microcarrier and provides a suitable surface for the attachment and growth of anchorage-dependent mammalian cells. It is effective for plating fastidious cells, including many epithelial, endothelial, neural and myoblastoid cells which may otherwise not attach. It dramatically increases cloning efficiency and helps minimise the variability in plating efficiency associated with different serum lots. Investigators wishing to define the growth factor and nutrient requirement of cell lines, for example, will find CR-HFN a useful aid. The range of Collaborative Research tissue culture products now includes epidermal growth

ACCURAMATIC DUO-SPEED AMPOULE FILLER/MEDIA DISPENSER

PRICE £520 + VAT

Filling range: 3mm bore tube. Low speed 0.5ml to 20 ml
High speed 2ml to 75ml
8.5mm bore tube. High speed 25ml to 550 ml
Filling Time: Up to 14 seconds depending on volume required.
Electrical requirements: 210-250 V. 50Hz. 1 amp.

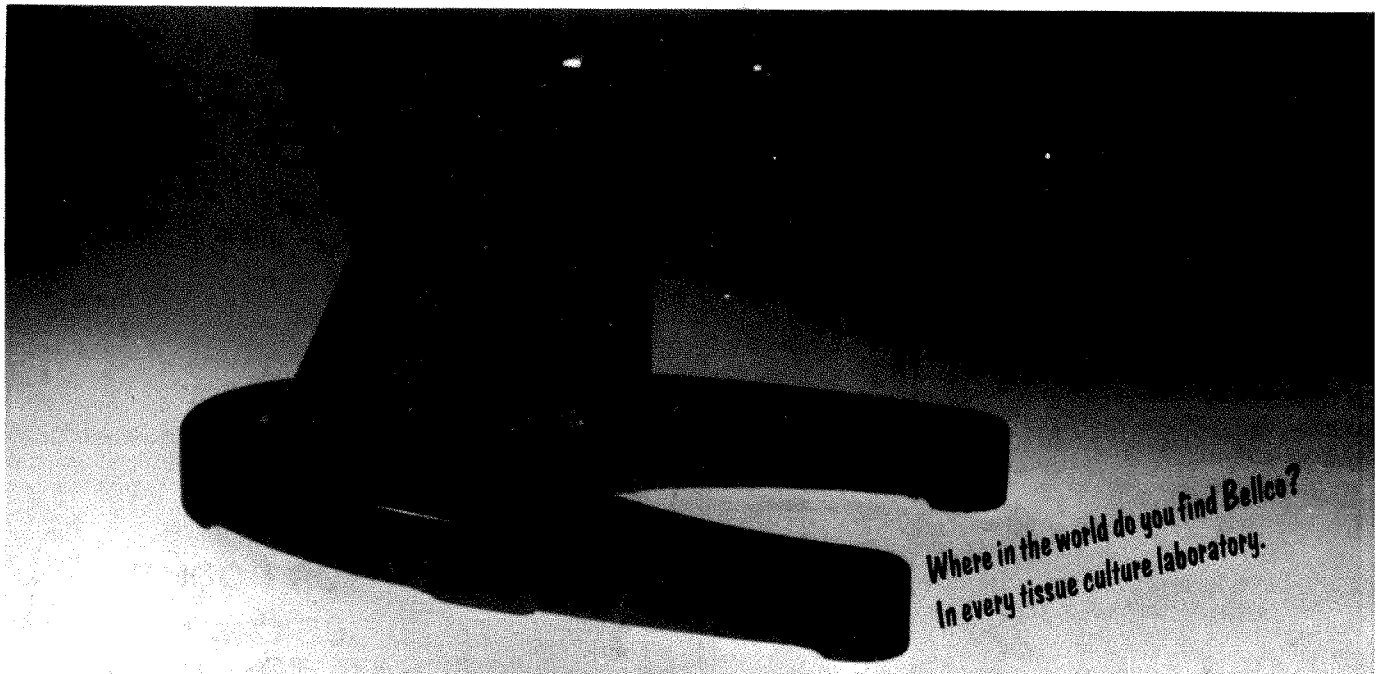
Duo-Speed Accuramatic is supplied complete with 3 mm bore and 8.5 mm standard bore tubing assemblies and a footswitch. Intermediate delivery tubing sizes to give deliveries other than those listed are available to suit your particular requirements.

For bacteriologists, microbiologists, virologists, pharmacists, pathologists, public health laboratories — anyone who has a requirement for an automatic dispenser.

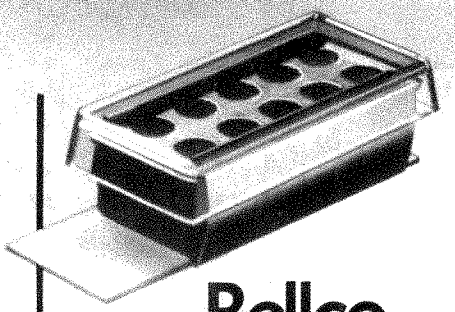
Dispenses at the touch of a button 0.5ml to 550ml with accuracy of approximately ±1% midrange, or automatically with a variable interval between doses. Footswitch allows normal single-dose operation or acts as a safety overrider when automatic function is selected.

Peristaltic pump output is directed to delivery tube. Suspensions and sterile solutions can be filled. In-line filtration is easily set up. Stepless volume adjustment can be made while Accuramatic is running. The delivery nozzle can be remote from the machine such as in a controlled environment cabinet. Separately sterilised tubing assembly can be installed in pump and solenoid clamping heads in less than a minute. Delivery time between doses in automatic function can be varied from 0-5 seconds, and in manual function filling is as quick as the dexterity of the operator will allow. The Accuramatic incorporates a carrying handle and is easily portable.

Using the low speed of the Duo-Speed Accuramatic ensures accurate, steady and constant filling of small containers without splash or overspill and also prevents bubbles and frothing which can cause inaccuracies. The high speed setting is suitable for routine dispensing.



Accuramatic advantages



No valves, pistons or moving parts in contact with liquid, only silicone rubber tubing and glass fittings, so easily sterilised and changed. Printed circuitry is easily replaced, simple to service, front panel lifts away. Demonstration on request in most areas. The turn of a wheel — sets the delivery rate to your selected volume.

Bellco Micro-Slide Culture Chamber*

*U.S. PATENT 3,883,398

For convenient tissue-culture, immunology and virology . . . the Bellco Micro-Slide Culture Chamber. Non-toxic, autoclavable, with silicone-rubber matrix. Ten micro-culture wells. Each has 0.4-ml volume to provide ten 0.317 cm^2 monolayer growth areas. Use with standard 25 x 50 mm microscope slide. Stainless-steel side clips and top-pressure plate for quick, convenient assembly. Can be autoclaved intact with transparent cover.

On a micro-culture level, assay any substance that affects mammalian cells. Autoradiography. Cell differentiation. Cytotoxic antibody titrations. Immunofluorescence. Lymphocytotoxicity assays, optical or radio-isotopic. Viral cytopathogenic effect and screening.

Wells will not leak at contact point with microscope slide. Polyester film can be used between slide and matrix. Matrix will not disturb monolayers during disassembly. Results can be retained on microscope slides.

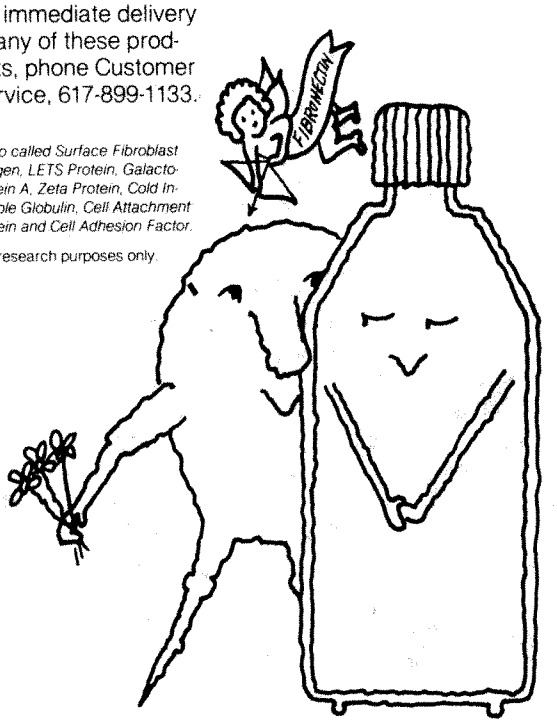
OUR FIBRONECTIN MAKES YOUR CELLS GROW ATTACHED TO CULTURE FLASKS . . .
and other growth surfaces.

If you have had disappointing results trying to grow cells in culture, we may have the remedy . . . our Human Fibronectin (CR-HFN). This product has repeatedly proven effective in getting fastidious cells to attach to surfaces—and grow.



CR-HFN, — a glycoprotein cell surface antigen*— adsorbs to surfaces to provide a hospitable environment for anchorage-dependent cells. Cells which were previously impossible to culture, now grow. Plating efficiency is dramatically increased. And the variability of plating with different serum batches is reduced or eliminated.

At Collaborative Research, we're committed to the development of products which make tissue culture a dependable science. CR-HFN is the latest addition to our growing line of tissue culture products—including Epidermal Growth Factor, Fibroblast Growth Factor, Nerve Growth Factor, Multiplication Stimulating Activity, Endothelial Cell Growth Supplement, and Human Thrombin.

To find out more about these products and what they can mean for your research, write or call today. Or for immediate delivery of any of these products, phone Customer Service, 617-899-1133.

*Also called Surface Fibroblast Antigen, LETS Protein, Galactoprotein A, Zeta Protein, Cold Insoluble Globulin, Cell Attachment Protein and Cell Adhesion Factor.

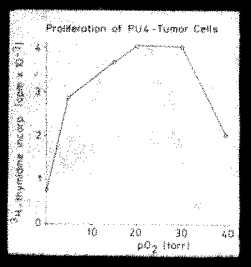
A new approach in tissue culture

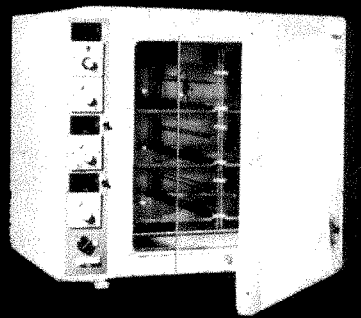


PETRIPERM

a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents



PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable [illegible] µm thick membrane.

Heraeus— Co_2-Incubator B 5060 EK/CO_2

We build the incubator with appropriate pCO_2, pH and pO_2 control units

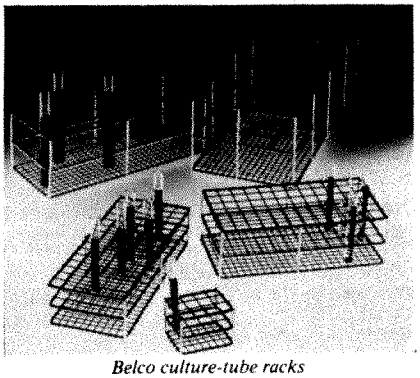
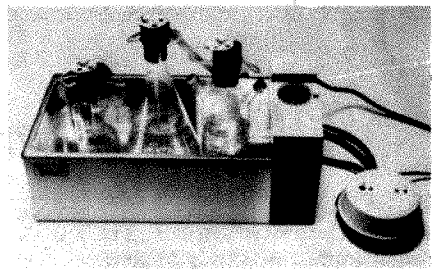
Circle No.97 on Reader Enquiry Card.

HERAEUS



A new approach to tissue culture is announced by Heraeus, the Petriperm culture dish. This dish is fitted with a gas-permeable membrane which acts as a cellular support. The membrane can be cut for cell cloning, electron microscopy or staining. They are suitable for high-power light and fluorescence microscopy, transparent to UV light at 200 nm and resistant to acids, bases and organic solvents. Petriperm is produced with either a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells. the use of a gas-permeable membrane in this way allows for a more precise control of partial levels of dissolved oxygen, carbon dioxide and hydrogen ions. The Heraeus type B 5060 EK/CO_2 incubator achieves accurate control of levels of CO_2, oxygen and *p*H.

Circle No.96 on Reader Enquiry Card.



BELCO GLASS INC.

Stainless steel racks are available from Belco Glass Inc. in 23 standard configurations for all popular-size culture tubes, including 13, 16, 18, 20, 22, 25 and 38 mm. These racks, each designed to handle from 12 to 150 culture tubes, are made from heavy-gauge wire with turned-edge construction. Rust resistance and long life in carbon-dioxide incubators and water baths are assured by an electropolished finish. An extensive range of glassware for tissue culture is available from Belco. Two types of hanging-bar spinner flasks are produced, one fitted with central rubber stoppers and one with central plastic screw caps.

Circle No.95 on Reader Enquiry Card.

Belco culture-tube racks

Techne's air-driven stirrer

TECHNE

The 'classical' stirrer for suspension cell culture consisting of a suspended, rotating horizontal magnetic bar is not well suited for the suspension of microcarriers. For this application Techne produce a stirrer driven by a three-phase air supply (the pneumatic equivalent of three phase electricity). It consists of a vertical glass rod operated by a completely heatless, autoclavable, air motor mounted on the screw cap of a glass flask containing the medium and microcarriers; there are no rotating bearings in the flask. The flask can be stood in any water bath.

Circle No.94 on Reader Enquiry Card.

BIO-RAD

Bio-Rad Bio-Carriers are an improved, high-strength polyacrylamide microcarrier developed to supply the need for an efficient and inexpensive method of culturing mamalian cells-including primary, diploid and established lines. In Bio-Carrier culture, anchorage-dependent cells grow on the surface of small, positively charged beads suspended in nutrient medium by gentle stirring or agitation. With Bio-Carriers, a single 1-litre spinner flask can be used to grow as many cells as 20 half-gallon roller bottles. Or, the beads can be added to flasks, Petri dishes or roller bottles for six- to sevenfold increase in surface area. Bio-Carriers conform to all parameters, defined over more than a decade of research, which promote optimal attachment and growth of a wide variety of cell lines. Bead charge is carefully controlled and evenly distributed; beads are narrowly sized (120–180μm) have a specific gravity of 1.04, which promotes homogeneous suspension, and are transparent for microscopic viewing of cells. Bio-Carriers are an improvement over previously available materials, because the cross-linked polyacrylamide is better able to withstand the forces of stirring and cell growth without breaking up. Cells can be cleanly separated from Bio-Carriers with no mixture of disintegrated bead fragments, a recurring problem with many other microcarriers. The inert polyacrylamide matrix also makes Bio-Carriers impervious to bacterial or enzyme attack.

Circle No. 93 on Reader Enquiry Card.

ASSAB LTD

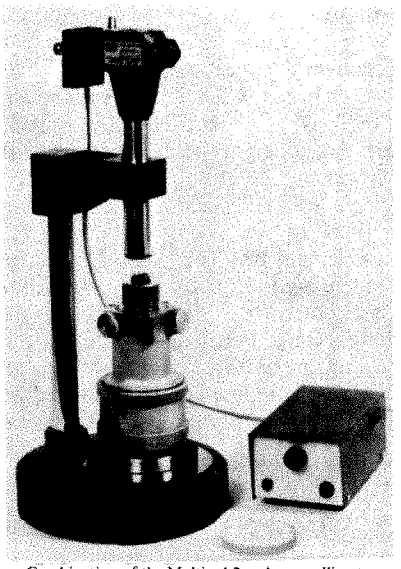
Assab have had 10 years' experience in marketing their automatic CO_2 incubators in the UK and are now firmly established in the NHS and other fields. The product range embraces anhydric, cooling and CO_2 incubators, an anaerobic work station and dry air sterilisers. Within the last 3 years Assab have also introduced their system of controlled temperature installations. The system can be adapted to existing rooms or is available as a complete package including an insulated cubicle. The emphasis here is on control, with accuracies up to ± 0.2°C, and reliability. The system is inherently reliable but by duplication of controls a 'fail safe' situation can be achieved. Installations have already been carried out for the major pharmaceutical companies for uses ranging from incubation to package testing.

Circle No. 92 on Reader Enquiry Card.

BILLUPS-ROTHENBERG

The modular incubator chamber produced by Billups is a convenient and efficient alternative to conventional continuous flow and anaerobic incubators. The experimental apparatus is placed in the sealed chamber which is then purged with the required gas mixture and the system is kept in a controlled-temperature environment. As cultures can be set up in separate isolated cells it is economical and practical to vary culture conditions. Chamber and tray components are made from rugged non-toxic UV-resistant polycarbonate. The trays can accommodate Petri dishes, test tubes, tissue culture flasks, microtest plates and so on. The chambers may be stacked and interlocked for agitation or for storage.

Circle No. 91 on Reader Enquiry Card.



W.T. WINGENT

Cell types which do not need to adhere to a surface for their proliferation can be efficiently cultured in the waterjacketed culture spinner vessel produced by Wingent. Spinners are run by magnetic stirrer and a water circulator is required to supply the water jacket: one circulator can be used to supply several culture vessels. Each spinner can be fitted with four openings: one for continuous supply of the appropriate gas mixture; one as an outlet for pressure equalisation; one opening to take a glass tube to the bottom of the vessel for sampling; and one opening to permit addition of culture fluid as required. The Wingent vessel has been used successfully for many types of animal cell and human cells derived from normal and malignant tissue.

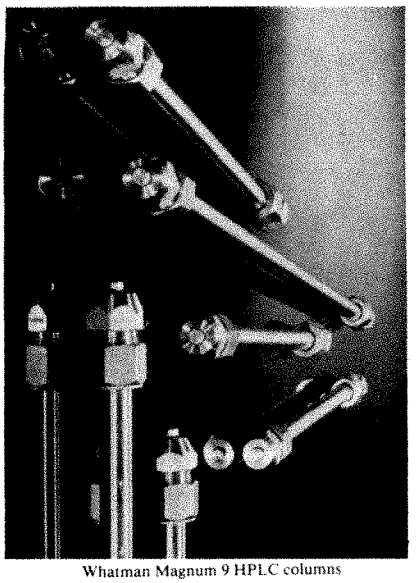
newly on the market

Precision polishing machine. Metals Research. Using the Mark II polishing jig with the 'Multipol 2', together with the associated autocollimator system, laser rods are being routinely polished to a flatness better than $\lambda/10$ and parallel end-to-end within 2 arc s. The Multipol 2 is a precision polishing machine designed specifically for polishing metals, glass, semiconductors and soft optical crystals using either abrasive, etch or wet slurry polishing techniques. It can also be used to handle metallurgical, mineralogical and biological specimens using a wide variety of polishing media and a range of lap surfaces of up to 200 mm diameter for optimum surface finish. Using optical alignment provided by the autocollimator, the two faces of the laser rod are polished at 90° to the rod axis to a high degree of parallelism.
Circle No. 64 on Reader Enquiry Card.



Combination of the Multipol 2 and autocollimator

Reagent for detection of reducing sugars. Pierce. The copper-bicinchoninate (Cu-BCA) reagent is used as a stable non-corrosive dye reagent for detecting sugars separated by ion-exchange of their borate complexes using an automated sugar chromatography system. A better peak resolution can be achieved than with the viscous sulphuric acid reagent. Reaction times less than 1 min and reaction coils with i.d. down to 0.3 mm were used. Owing to the high baseline stability of the detection system with the Cu-BCA reagents, the analyser can be run at higher sensitivity. The colour formation is linear over a detection range of more than two orders of magnitude. In routine work, amounts of 0.1–30 μg of different sugars have been determined.
Circle No. 65 on Reader Enquiry Card.

Shell freezer. FTS Systems. The Just-A-Tilt, manufactured by FTS Systems, will process up to four 1,200-ml freeze-drying flasks and shell-freeze 2.4 l of sample in under an hour. There are no flask-lift devices or rollers to adjust, even if samples are in different-sized containers, as all are rotated in a thin film of —40°C alcohol pumped from a mechanically refrigerated heat exchanger. Full alcohol volume is only 1.5 l. Shell-freezing flask angle is infinitely adjustable from front-mounted control between 0° (flat) and 16° (inclination) to present a more uniform wall thickness and faster, more even freeze-drying rates. Clear plastic top permits frost-free visibility of flask during processing.
Circle No. 66 on Reader Enquiry Card.

Ribonuclease H-1 from calf thymus. Enzo Biochem. The ribonuclease H-1 now available from Enzo Biochem was purified from calf thymus using polyethylene glycol CM-Sephadex, Cellex-CM, DEAE, and affinity chromatography. This enzyme can be effectively used in the digestion of the RNA moiety of the hybrid after reverse transcriptase assays; to avoid the de-amination of cytidine in the cDNA; in the removal of the poly (A) stretches found on the RNA messenger; as a restriction enzyme with trideoxynucleotides on the DNA matrix; it will preferentially act on the guanosine moiety.
Circle No. 67 on Reader Enquiry Card.

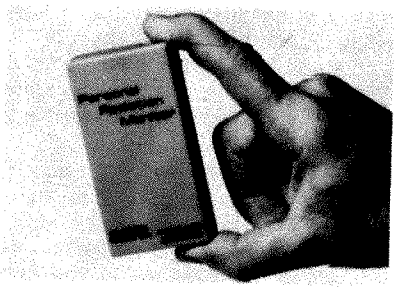
Pre-pleated filter papers. Schleicher and Schuell. To introduce the benefits of their pre-pleated filter papers, a three-pack sampling of three different grades of the filter paper is available free from Schleicher and Schuell. The pre-pleated filter paper affords twice the exposed surface area of ordinary filter paper that is hand-folded into quadrants and provides a significant time-saving by allowing solid-liquid separations to move faster. Since solids are more evenly dispersed over the paper's surface, clogging is reduced or eliminated. Widely used to recycle reagents in chemistry autoanalysers, S&S filter papers are burst-proof when used under normal laboratory conditions. They retain precipitates from course to fine in six standard grades and 10 standard diameters from 12.5 to 50.0 cm. The free three-pack includes a total of 75 pre-pleated filters, 25 each of three filtration speeds: fast, medium and slow. When ordering the free three pack, specify diameters: 12.5 cm, 18.5 cm or 24.0 cm.
Circle No. 68 on Reader Enquiry Card.

Whatman Magnum 9 HPLC columns

Preparative HPLC columns. Whatman. The new, modified Magnum 9 columns from Whatman permit yields of up to 2.5 g of highly purified compound. They can be fitted to any analytical liquid chromatograph and obviate the need for preparative instruments for laboratory scale preparations. An important benefit of the modified Magnum 9 columns is that they permit simple scale-up from corresponding Partisil analytical columns. Only the flow rate need be controlled to maintain an equivalent linear velocity in this scale-up. Modified Magnum 9 columns are 9.4 mm I.D. × 12.7 mm (½") O.D. × 50 cm long, 316 stainless steel with LDV outlet to fit any liquid chromatograph.
Circle No. 69 on Reader Enquiry Card.

Laboratory chest freezer. Forma Scientific has introduced a new 3 cu. ft laboratory chest freezer with an ultra-low temperature range of —75° in a warm +90°F ambient temperature; improved stainless steel interior construction; minimum of 5" foamed-in-place urethane insulation; built-in battery-operated ring back alarm system with self-charging nickel cadmium batteries; built-in indicating controller with automatic over-temperature safety; dual wheel castors for mobility; easy-opening counterbalanced lid. The freezer is available in both 120V, AC, 60 Hz and 220V, AC, 50 Hz models.
Circle No. 70 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.



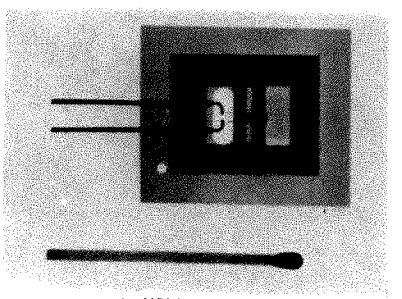
Pressure transmitter. Philips. A new range of compact industrial transmitters which measure pressure in gases and liquids from 1 bar up to 100 bar, is announced by Philips. The PR 9390 series of pressure transmitters operate according to the piezo-resistive principle and comprise a sensor with pressure-sensitive silicon crystal and an integral semi-conductor full bridge strain gauge network. A built-in amplifier produces a standard 0–20 mA load – independent output signal, proportional to the applied pressure and allowing direct connection of indicating, recording or other equipment. The transmitters require an unstabilised 24 V d.c. power supply and are supplied as standard with a 2-m long integral connection cable. The compact housing and pressure connections are made of a highly corrosion-resistant steel and are completely sealed.
Circle No. 71 on Reader Enquiry Card.

Angle head centrifuge. Gallenkamp. The compact angle head centrifuge now produced by Gallenkamp has a maximum capacity of 120 ml and the eight-place angle head will accept tube sizes up to 15 ml. A solid-state power controller enables the operator to adjust the speed of the centrifuge. Top speed is 5,000 r.p.m. and maximum RCF is 2,500*g*. Safety features of the centrifuge are that the lid must be properly closed before the centrifuge will start spinning and both the head and the motor are completely enclosed in a robust steel case. The self balancing action of the mounting makes critical balancing of tubes unnecessary.
Circle No. 72 on Reader Enquiry Card.

The Gallenkamp centrifuge

Digital field synchroniser. Marconi. the B3565 digital television field synchroniser is the latest addition to the range of equipment from Marconi Communication Systems. The equipment has the storage capacity of one television field as distinct from a frame synchroniser which stores two fields, thus reducing the cost and size to a minimum.
Circle No. 73 on Reader Enquiry Card.

The Andrex radiation monitor



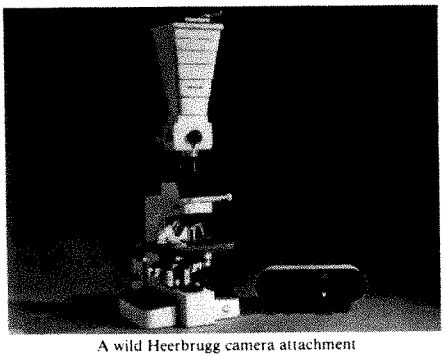
Pocket radiation monitor. Andrex Radiation Products has introduced a new version of its personal radiation monitor that is both lighter and smaller than previous models, but provides the same high level of performance. The monitor provides an instant audible warning of potential radiation hazards. The sensitivity setting is from 1 mR h^{-1} and the unit is activated by simply removing a disposable 'shipping plug'. Once activated the unit, powered by a 1.5 V battery, remains 'on' continuously, producing an intermittent reference bleep to confirm operation and battery condition. Bleep speed increases as radiation levels rise. With a weight of 80 g, the monitor can be clipped to a belt or slipped conveniently into a pocket.
Circle No. 74 on Reader Enquiry Card.

Triiodothyronine uptake kit. Amersham Corporation announce the availability of its new T_3 uptake (MAA) kit. The kit is designed to provide a rapid and convenient assessment of thyroid hormone binding capacity in human serum. The kit protocol depends on the distribution of ^{125}I-triiodothyronine between vacant binding sites on endogenous binding proteins and a secondary binder in the form of macro-aggregated albumin. Speed, accuracy and convenience are assured with a 50-μl sample, 10-min room temperature incubation and excellent correlation with the clinical picture. Kits containing sufficient reagents for 50, 100 and 400 single determinations are available.
Circle No. 75 on Reader Enquiry Card.

Coater for low-temperature sputtering. Edwards. Heat-sensitive specimens for scanning electron microscopy work can now be coated safely with the Edwards S150A, a new bench-top sputter coater. A new deposition system maintains very low specimen temperature. It incorporates an electrode design which suppresses high energy electrons which would otherwise lead to specimen heating. A two-magnet electron deflection system reduces secondary electron bombardment of the specimen and a large water-cooled specimen table absorbs heat and reduces plasma density. A carbon evaporation accessory can easily be fitted for depositing films onto specimens for X-ray microanalysis.
Circle No. 76 on Reader Enquiry Card.

Radiation measuring system. Radiation Components. The Diamentor-D radiation monitoring system from Radiatron Components enables instructors to use the system to demonstrate visually the extent of a patient's exposure to ionising radiation, allowing students to learn radiological techniques more quickly and thoroughly. Its accuracy in diagnosis and value as a teaching aid are derived from the fact that it measures the total useful output from the X-ray tube. The Diamentor-D system comprises a flat, transparent, rectangular ionisation chamber which is mounted on the light beam diaphragm or under couch tube. This is linked by a screened cable to a unit which displays the area exposure continuously in R cm^{-2}. It can also display screening time. The ionisation chamber is available in two sizes and can be easily fitted to any make of X-ray equipment. It has a filtering effect equivalent to 0.5 mm of aluminium.
Circle No. 77 on Reader Enquiry Card.

Strain gauges. HBM. The free grid strain gauge LF 30 for measuring strains at high temperatures has been developed by Hottinger Baldwin Messtechnik. The measuring grid consists of a platinum–tungsten alloy and is attached to a self-adhesive glass-fibre-reinforced Teflon backing strip, which is discarded during the mounting operation. The strain gauge is mounted with ceramic cement or by using the flame spraying process. The free grid strain gauges LF 30 are obtainable with measuring grids 3 mm and 6 mm long. They can be used at temperatures of up to 1,000°C depending on the mounting process and the type of stressing.
Circle No. 78 on Reader Enquiry Card.



An HBM strain gauge

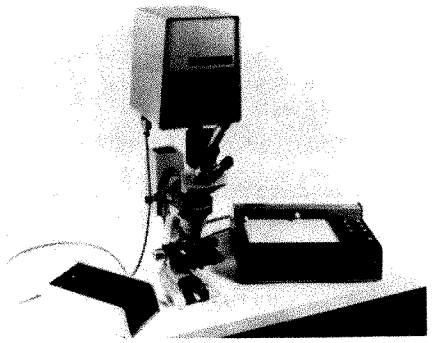
3-D Bench system. Oriel announces a new range of benches contained in a 28-page catalogue. The Oriel three-dimensional optical bench consists of a 3½ inch (8.89cm) diameter thick-walled aluminium tubing extruded with four symmetrical dove-tails. These are available in various lengths. A variety of connectors and fittings will connect these to each other to form very rigid structures in almost any configuration. Any standard sized Oriel carrier can be mounted on any of the four dove-tails. Almost any Oriel accessory can be mounted on these benches. Other instruments or lasers can be readily mounted using the flat-topped Oriel carriers.
Circle No. 79 on Reader Enquiry Card.

High-performance fluorescence spectrophotometer. The Perkin-Elmer Model 650-40 fluorescence spectrophotometer is the first high-performance instrument available with microprocessor control of ordinate and abscissa function. The optical system of the Model 650-40 uses concave gratings which are driven by stepper motors under microprocessor control. With a wavelength range of 200–850 nm, the instrument uses a reference photocell in monochromatic light to achieve a ratio recording system. Horizontal slit imaging allows enhanced sensitivity and smaller sampler volumes. All operational modes, with the exception of slit control, are selected from a keyboard containing both function and numerical keys. Selections from the keyboard include: scan speed, auto-zero, zero suppression, integration, concentration, response time and photomultiplier gain. A prescan mode function incorporated into the microprocessor allows either the excitation or emission monochromator to be scanned at 960 nm min^{-1} for automatic location of peak maximum.
Circle No. 80 on Reader Enquiry Card.

Camera attachments. Wild Heerbrugg. With three camera attachments by Wild Heerbrugg, photographs are now possible up to 4 in × 5 in. The 1.0× camera attachment, in addition to making possible the exposure of 4 in × 5 in or 9 cm × 12 cm cut film, also enables photographs to be taken on Polaroid cameras on 3¼ in × 4¼ in filmpack and 4 in × 5 in cut film. With the 0.8× camera attachment, 6 cm × 9 cm (cut or roll film), 4.5 cm × 6 cm and 6 cm × 6 cm photographs are possible.
Circle No. 81 on Reader Enquiry Card.

A wild Heerbrugg camera attachment

Electronic balances. Oertling introduce the Alpha 22 series of electronic balances. All models are alpha-numeric with a clear LED readout, and are dual range, with capacities of 2 kg to 0.1 g and 200 g to 0.01 g, with a fully subtractive tare. The balance is protected against overload, as 'OVER' appears on the display as a warning signal. The HC22/51 model has several extra features, including a store and recall facility. Up to eight weights can be stored for later recall. The operation of pressing the 'store' button also sets the reading to zero.
Circle No. 82 on Reader Enquiry Card.



Electrophoresis power supply with digital readout. Buchler Instruments has introduced a junior version of its popular 3-1500 power supply to provide a reliable, lower voltage method for electrophoresis applications. This new unit, the DPS-350, uses push-button controls to select the appropriate output ranges and regulation modes. Constant voltage and constant current levels may be selected up to 350 V d.c. and 100 mA. This output is controlled by a 4-turn potentiometer and offers the user full burn-out protection. This unit will automatically switch over from one mode to another whenever the load demand is excessive in the original mode. The large LED display allows easy and precise readings from any reasonable distance within a lab.
Circle No. 83 on Reader Enquiry Card.

Particle and droplet sizer. Malvern. The ST1800 particle and droplet sizer has been introduced by Malvern Instruments. Based on laser diffraction scattering the equipment measures the size distribution of solid particles or liquid droplets over the size range 1–500 μm with an optional extension to 1,800 μm. Full sample to answer facilities are enabled by computer control, making the instrument suitable for use by semi-skilled operators if required. A hard copy print out of the size ranges in 15 size bands is presented.
Circle No. 84 on Reader Enquiry Card.

Custom chip for wire chambers. A new low-level amplifier/comparator introduced by LeCroy provides a compact, high-speed monolithic 16-pin DIP for low-level pulse counting. Especially suited for multiwire drift chamber and proportional chamber applications, the device offers a threshold of typically ± 200 μV and time slewing of 1.5 ns from 2× to 20× threshold. A single chip, the MVL100 pulse detector, contains a 100-MHz wideband amplifier, a discriminator, a monostable output timer, an ECL line driver, and a 50Ω linear driver. Each section is designed without compromising performance. Both the input and the output are fully differential and compatible with twisted-pair signal transmission.
Circle No. 85 on Reader Enquiry Card.

Refrigerated centrifuge. Du Pont. A low-speed refrigerated centrifuge with 6-l rotor capacity has been introduced by the Du Pont Company's 'Sorvall' Instruments Division. The Sorvall RC-3B refrigerated centrifuge can be used to handle large sample volumes, or up to 420 radioimmunoassay tubes in a single run at relative centrifugal forces to 5,136g Features of the RC-3B include imbalance detection and indicator, automatic door interlock with zero speed detection, automatic over-temperature detection, and open-door interlock to prevent rotor start-up.
Circle No. 86 on Reader Enquiry Card.

Microspectrophotometer. Anaspec. A new microspectrophotometer is available from Anaspec, capable of obtaining spectra from samples or objects as small as 10 μm. The system is essentially a miniature photometer that will interface directly to the camera port of any laboratory microscope. A unique feature of the system is its microprocessor which utilises programmed 'PROMS' for ABS/TRANS conversion. The microprocessor will store both the base line 100%T and spectra for spectra normalisation, such that the system is capable of double-beam ratiometric operation.
Circle No. 87 on Reader Enquiry Card.

The Anaspec microspectrophotometer

Chromatography column eluate concentrator. ChemLab. With the new column concentrator from ChemLab which uses molecular retentive membranes, it is possible to increase the concentration of a compound in the eluate from a chromatography column by a factor of 3 or 4 and sometimes by as much as 10 times. The concentrator consists of two perspex blocks into which grooves in spiral form are accurately machined. A membrane is placed between the upper and lower blocks so that low molecular weight compounds pass through the membrane to the lower chamber, while the eluate from the column is passed through the upper groove, and during the passage of the liquid through this groove a concentration of the high molecular weight compounds takes place. The increase in concentration can be varied by a control valve which increases or decreases the back pressure in the line of the eluate from the column. The concentrator is designed for operation with chromatography columns working at flow rates of 10–200 ml h^{-1}.
Circle No. 88 on Reader Enquiry Card.

Brochure on ultra-low temperature freezers. Forma Scientific has published a new brochure detailing the company's entire ultra-low temperature freezer product line including chest, upright and walk-in models. The brochure includes information on the company's newest 3 cu. ft chest freezer, along with information on simulated power failure tests, blood storage freezers, safety back-up systems and inventory system selection.

APPOINTMENTS VACANT

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MICROBIOLOGY

Applications are invited for the following posts:

POST-DOCTORAL RESEARCH FELLOW

A post-doctoral microbiologist is required to join a major new project on corrosion studies on North Sea Oil structures, financed by the SRC Marine Technology Directorate. The research group will work in close collaboration with marine biologists and metallurgists in the University and Robert Gordons Institute of Technology, and in association with the major oil and service companies.

Appointment will be from 1 October 1979, and will be for one year in the first instance with possible extension for a second year. Salary within Range 1A, £4,910 to £5,770, with appropriate placing.

RESEARCH ASSISTANT

To work with Dr I R Booth and Dr W A Hamilton on the kinetics of ion-linked solute transport in bacteria, financed by SRC.

RESEARCH ASSISTANT

To work with Dr J I Prosser on the effects of surface and pH on the dynamics of nutrification in the soil, financed by NERC.

Salary in each case within Range 1B, £3,775 to £4,333, with appropriate placing. Appointment will be from 1 October 1979, for 1 year in the first instance with possible extension up to a maximum of three years. It will be possible for the successful candidates to register for a PhD.

Telephone The Secretary, The University, Aberdeen (0224 40241) for further particulars. Applications (2 copies) to The Secretary should be lodged by 10 August 1979. 2584(A)

COMMONWEALTH AGRICULTURAL BUREAUX

Vacancy for
SCIENTIFIC INFORMATION OFFICER

(Full-time or Part-time) at National Institute of Agricultural Engineering, Wrest Park, Silsoe, Bedford MK45 4HS, UK

Duties of Post: The scrutiny of technical literature, selection and preparation of abstracts on all subjects related to agricultural and horticultural engineering (this may involve visits to outside libraries), indexing, proof-reading, and dealing with technical enquiries.

Qualifications: Applicants should have a knowledge of both engineering and foreign languages. They should have a degree or similar qualification in engineering or a relevant subject and a high competence in at least one foreign language, or a foreign language degree with a sound background knowledge of engineering. The ability to write clear concise English is essential.

Salary: In the scale £2,839 to £5,448 (under review) plus a compensatory allowance to offset personal contribution to superannuation. Starting salary according to qualifications and experience. Promotion to higher scales on merit.

Application forms and full particulars from Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN. Closing date for applications 15 August 1979. 2588(A)

UNIVERSITY OF BATH

POSTDOCTORAL RESEARCH IN BIOCHEMISTRY

Applications are invited for the above post to work with Professor P D J Weitzman. The project is supported by the SRC and is concerned with structure-function relationships in variant forms of the enzymes citrate synthase and succinate thiokinase. Previous experience in enzymology and/or protein chemistry is essential.

The post is available as soon as possible, tenable for two-and-a-half-years. Salary in the range £4,333 to £4,910 per annum. Reference number 79/165.

GRADUATE RESEARCH OFFICER IN BIOCHEMISTRY

Applications are invited for the above post to work with Professor P D J Weitzman and Dr M J Danson on a project supported by the SRC and concerned with the oligomeric, catalytic and regulatory properties of citrate synthase variants. The appointee will be engaged in enzyme purification and a full range of protein chemical procedures. Candidates should have a good degree; previous relevant experience will be an advantage. The post is tenable for three years from 1st October, 1979. Starting salary in the range £3,775 to £4,333 per annum. Reference number 79/166N.

Application forms from the Personnel Officer, University of Bath, BA2 7AY, quoting appropriate reference numbers. Closing date will be 3rd August 1979. 2621(A)

KENYATTA UNIVERSITY COLLEGE KENYA

Applications are invited for the post of

LECTURER (ECOLOGIST) in the
DEPARTMENT OF BOTANY

Applicants must have a PhD in Botany wi specialization in either Terrestrial Aquatic Plant Ecology. They should ha had several years teaching experience University level, while teaching secondary school level will be an add advantage. The appointee will be expect to teach in the B.Ed undergradua programme and to supervise post-gradua students. He/she will be expected to initia and conduct research in the stated areas specialization. Salary scale: Lectur £2,016 to £3,312 pa (K£1 = £1.24 sterling The British Government may supplem salary in range £4,278 to £4,818 (sterling) for married appointee or £2,7 to £3,156 pa (sterling) for single appoint (reviewed annually and normally free fro tax) and provide childrens' educatic allowances and holiday visit passage Family passages; SSSF or FSSU subsidized housing; non-contributo medical aid scheme; baggage allowance.

Detailed applications (2 copies) wi curriculum vitae and naming three refere to be sent direct to the Registrar, Kenyat University College, P O Box 4384 Nairobi, Kenya by 15 August 197 Applicants resident in the UK should al send one copy to Inter University Counc 90/91 Tottenham Court Road, Londo W1P 0DT. Further details may be obtain from either address. 2603(A)

EXCERPTA MEDICA

is one of the largest scientific information services in the world, adding 230,000 items each year to its database.

We wish to recruit a

PROGRAMMER with 2 years' experience, who is also a

SCIENTIST interested or experienced in

INFORMATION WORK to assist with the development of a new system to meet the challenges of the 1980's.

Remuneration about £8,000 to £9,000 per year.

Further details from Prof. G.A. Somerfield, Excerpta Medica B.V., P.O. Box 1126, 1000 BC Amsterdam — The Netherlands.

ELSEVIER SCIENCE DIVISION

W232(A)

UNIVERSITY OF DUNDEE

POSTDOCTORAL BIOCHEMIST

Applications are invited for a SRC grant financed postdoctoral fellowship to work ir collaboration with Dr D G Nicholls on a project whose aim is to establish the molecular mechanism by which noradrenaline regulates the exothermic metabolism of isolated brown adipose cells. For reviews see Biochem. Soc. Trans. (1977) 908; New Scientist 13/4/78. The Neurochemistry Laboratory is located in the Department of Phychiatry, and has close tie with the Department of Biochemistry.

The post is available for up to two year from an early date to be agreed.

Salary within the range £4,232 to £4,776 (t be reviewed from October 1979).

Informal enquiries may be made t Dr D G Nicholls, Neurochemistr Laboratory, Department of Psychiatry Ninewells Medical School, University o Dundee. Applications, quoting referenc EST/61/79 J and containing the names o two referees should be lodged with Th Secretary, The University, Dundee DD1 4HN as soon as possible. 2572(A)

THE OPEN UNIVERSITY

Graduate Research Assistant in Physical Organic Chemistry

Applications are invited for the above post to work with Dr P G Taylor at the Open University for a period of three years commencing 1st October 1979, or as soon as possible thereafter.

The Research Assistant will participate in a research programme concerned with the study of the mechanism of Friedel-Crafts type reactions and in particular the cyclisations of substituted 2 (2-Naphthalenylmethyl) benzoic acids.

Candidates should be 23 years or under on October 1st 1979, and possess, or be currently completing, an honours degree in Chemistry (a I or IIA is preferable but not essential). The successful candidate will be encouraged to register for a higher research degree (BPhil, MPhil, or PhD).

The appointment will be made at the first point on the Graduate Research Assistant 1B scale and the commencing salary will be £3,689 (under review) plus U.S.S.

Application forms and further particulars are available from The Recruitment Office (JD3934/1), The Open University, P O Box 75, Walton Hall, Milton Keynes, MK7 6AL or telephone Milton Keynes 63404: there is a 24 hour answering service on 63868. Closing date for applications: 2nd August. 2558(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSICS

pplications are invited for a Science esearch Council supported

POSTDOCTORAL RESEARCH ASSISTANT

o work on the theory of tunnelling states in uperconducting metallic glasses. amiliarity with field theoretical chniques of solid state physics is sirable. The project is funded for three ars commencing as near after October 1st 79 as is practicable. The salary scale is ,689 to £5,321 pa depending on alifications. (Scale subject to revision as om 1st October, 1979.)

Applicants should write to B L Gyorffy, niversity of Bristol, H H Wills Physics aboratory, Bristol BS8 1TL, before ctober 1st, 1979. 2620(A)

UNIVERSITY OF BATH

POSTDOCTORAL RESEARCH
Plant Sciences

plications are invited for a two year pointment funded by the SRC to work h Dr A D Dodge in the School of ological Sciences. The work is in the area plant membrane damage with particular erence to singlet oxygen induced oxidation of isolated chloroplasts.

Candidates should be or expect shortly be postdoctoral; experience of lipid alysis would be an advantage. Starting ary in the range up to £4,910 per annum. Application forms from the Personnel ficer, University of Bath, Bath, BA2 Y, quoting reference number 79/163N. sing date will be 3rd August 1979. 2597(A)

CSIRO AUSTRALIA

Research Staff
Division of Human Nutrition
Adelaide South Australia

CSIRO has a broad charter for the conduct of scientific and technological research for the benefit of the Australian community; it has approximately 7000 employees, located in Divisions and Sections throughout the country, of whom 2200 are professional scientists.

GENERAL: The Division is conducting multi-disciplinary research into nutritional factors, biological mechanisms, and disease processes. Its programs comprise experimental studies in inorganic nutrition (micronutrients) and in metabolism and digestion (macronutrients), and epidemiological and behavioural studies in human populations. Appointees are being sought in the program on Metabolism and Digestion which comprises (1) Diet & Metabolic Regulation, (2) Digestion & Lipid Metabolism, (3) Protein Turnover. The projects examine the role of dietary and environmental factors on metabolic disorders in man. Experimental models include, mice, rats (normal & genetically obese), marmosets and pigs. Studies with isolated liver and fat cells are in progress; tissue culture techniques are established.

FIELD: *Diet and Metabolic Regulation*. This group is examining the mechanisms associated with the efficiency of utilization of nutrients, hormonal control relevant to overnutrition and obesity and metabolic disorders associated with hormonal imbalances. Three appointments are proposed in this area, including one to replace the senior scientist who will retire in March 1980.

1. Endocrinologist — Biochemist — REF 250/271

DUTIES: To initiate research in the field described above. Collaborate with other research workers at the Division and at hospitals and medical schools.

QUALIFICATIONS: A PhD or MD degree or equivalent qualifications with research experience in endocrinology and biochemistry or clinical biochemistry and evidence of ability to lead a research team. A background in metabolic endocrinology with a bias towards mechanistic studies on peptide hormones would be an advantage.

SALARY: Senior Research Scientist (SRS) or Principal Research Scientist (PRS). Appointment of an outstanding candidate at a higher level would be considered.

2. Biochemist — REF 250/272

DUTIES: Develop research on the efficiency of utilization of nutrients with particular reference to carbohydrate metabolism and lipogenesis.

QUALIFICATIONS: A PhD degree or equivalent qualifications in biochemistry with appropriate postdoctoral experience. A background of isotopic labelling techniques in the study of intermediary metabolism and energy-dissipating cycles. Experience in the preparation and use of isolated cells and perfused organs.

SALARY: Research Scientist or Senior Research Scientist.

3. Biochemist (Postdoctoral Research Fellow) — REF 250/273

DUTIES: Research in the area of Metabolic Regulation, most likely in association with the appointee to Position 1.

QUALIFICATIONS: A PhD degree in biochemistry or equivalent qualifications.

SALARY: Research Scientist

FIELD: *Digestion and Lipid Metabolism*

4. Biochemist — Physiologist — Ref 250/274

DUTIES: Investigation of nutritional and physiological factors associated with metabolism of lipids relevant to atherogenesis and obesity.

QUALIFICATIONS: A PhD degree or equivalent qualifications. Formal training in biochemistry and physiology. Several years' postdoctoral research experience in lipid metabolism, together with a background in whole animal studies and knowledge of organ perfusion methods. An appreciation of epidemiological research is desirable.

SALARY: Research Scientist or Senior Research Scientist.

TENURE:
Positions 1, 2 and 4 — indefinite with superannuation.
Position 3 — a fixed-term of two years.
Note — Positions will not be available before April 1980.

SALARY:

Research Scientist	$A15,422 to $A18,904 pa
Senior Research Scientist	$A19,572 to $A22,405 pa
Principal Research Scientist	$A23,247 to $A26,368 pa
Senior Principal Research Scientist	$A27,790 to $A30,530 pa

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting the appropriate reference number(s) should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, London WC2R 3EH by 18th August, 1979. Applications in USA and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue NW, Washington DC 20036 2612(A)

UNIVERSITY OF GLASGOW

ADMINISTRATIVE ASSISTANT

INSTITUTE OF VIROLOGY

READVERTISEMENT

Applications are invited from university graduates for the post of Administrative Assistant in the Institute of Virology. Salary will be on Grade 1B of the scales for Administrative Staff (£3,775 to £6,355 from 1st October, 1979), with placing according to qualifications and experience. A degree in science, preferably biological, is desirable but not essential.

Further particulars may be obtained from the Secretary of the University Court (Room 18), University of Glasgow, Glasgow G12 8QQ, with whom applications (8 copies), giving the names and addresses of three referees, should be lodged on or before 3rd August, 1979. In reply please quote Ref. No. 4434/1M. 2600(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF BOTANY

Applications are invited from Botanists, Biologists and Biochemists for several posts of

POSTDOCTORAL RESEARCH ASSISTANT

for two years from 1st September, 1979 or later by arrangement.

For one post, plant physiology or histochemical experience is required and for another, knowledge of recombinant DNA technology.

Initial salary £4,232 or £4,505 (£4,333 per annum and £5,622 per annum from 1st October 1979) within Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by 27 July 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 2557(A)

UNIVERSITY OF BATH

SCHOOL OF PHARMACY & PHARMACOLOGY

RESEARCH OFFICERS IN MEDICINAL CHEMISTR

Applications are invited for the above pos for work with Professor R T Parfitt on th synthesis of novel analgesics related t morphine, and tropanes with centr nervous activity. Candidates should have PhD Degree in Medicinal Chemistry Organic Chemistry and have experience synthetic organic chemistry.

One post is tenable for a period of thr years from 1st October 1979, the other for period of 2 years.

Starting salary will be in the range up t £4,910 per annum.

Further particulars and applicatio forms are available from the Personn Officer, University of Bath, Bath, BA 7AY, quoting reference numb 79/116RN. Closing date will be 6th Augu 1979. 2634(A)

CSIRO AUSTRALIA

Research Scientist
Division of Fisheries & Oceanography Sydney N.S.W.

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

FIELD: *Physical Oceanography*

GENERAL: The Division is Australia's principle marine research institution with over 80 scientists investigating the physical, chemical and biological features, including fisheries, of the seas around Australia. Headquarters of the Division are in Sydney with regional laboratories in Perth and Brisbane. On-line access to a CYBER 76 computer is available. Sea-going facilities include two medium sized chartered vessels and several smaller vessels. The appointee will be located in Sydney.

DUTIES: As Head of the Physical Oceanography Group of ten scientists, the appointee will be a senior physicist who will be responsible to the Chief of the Division for the overall planning, organization and execution of the Division's programs in physical oceanography, and will be expected to ensure that these are closely co-ordinated with work in chemical and biological oceanography and in fisheries.

The appointee will also initiate and personally carry out research in physical oceanography in a field to be agreed on with the Chief of the Division.

QUALIFICATIONS: For such a senior appointment, a person with extensive research experience, and with managerial ability is sought. Minimum qualifications are a PhD or equivalent in an appropriate branch of science (physics, mathematics or engineering), together with considerable experience most of which should be in physical oceanography. It would be an advantage if this experience were in one of the fields presently regarded as directly relevant to the Division's work, namely dynamics of mesoscale water movements and dynamics of circulation over continental shelves and slopes. Ability to work at sea is essential.

SALARY: Dependent upon experience, but within the ranges:
Principal Research Scientist: $A23,247-$A26,368 pa
OR Senior Principal Research Scientist: $A27,790-$A30,530 pa

TENURE: Indefinite with superannuation.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 320/626 should reach The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 18th August, 1979.

Applications in USA and Canada should be sent to The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, NW, Washington, DC 20036, USA.

2609(A)

FLOW LABORATORIES LIMITED

Flow Laboratories Limited are looking for the following highly motivated personnel to join their Research Staff at Irvine.

R & D OFFICER

This person will have a Doctorate in Biochemistry, Cell Biology, or Microbiology and will be familiar with cell culture, protein purification and protein labelling techniques.

R & D ASSISTANT

This person will be qualified in the fields of Biochemistry, Genetics or Immunology and be familiar with enzymatic and radioisotope techniques. Experience in karyology or hybridisation would be an advantage.

Apply in writing, giving brief career details, to:
Mrs E McConnell, Personnel Secretary,
Flow Laboratories Limited, PO Box 17, Second Avenue,
Industrial Estate, Irvine KA12 8NB

2635(A)

UNIVERSITY OF GLASGOW
DEPARTMENT OF ZOOLOGY
RESEARCH ASSISTANT

Applications are invited for the above post, to work with Dr P Calow on a programme concerned with ageing in flatworms. Applicants should have a good honours degree in zoology or biology. Registration for a higher degree may be possible. Tenure is for 3 years and is subject to the standard conditions of SRC. Salary will be within Range 1B of the scales for Research and Analogous Staff (£3,689 to £4,232). The post is superannuated.

Further details from, and applications (a curriculum vitae plus names and addresses of two referees) to: The Secretary, Department of Zoology, University of Glasgow, Glasgow G12 8QQ. Closing date 4th August, 1979. In reply please quote Ref No 4489M. 2601(A)

SOIL MICROBIOLOGIST

Applications are invited for the above post for multidisciplinary effort to develop grass/legume pastures under acid soil conditions. Responsibilities include the isolation and evaluation of rhizobial strains for promising legume germplasm and the development of inoculation technology for pasture management. Studies on survival, movement and competitive abilities of introduced rhizobia in acid soils are envisaged. The applicant should have a PhD in microbiology. A working knowledge of Spanish would be desirable. The position is located at CIAT headquarters in Cali, Colombia.

Send application with curriculum vitae and three references to: Dr Gustavo A. Nores, Director for Land Resources Research, Centro Internacional de Agricultura Tropical, Apartado Aéreo 6713, Cali, Colombia. Applications required by October 15. W245(A)

COMMONWEALTH AGRICULTURAL BUREAUX
Vacancy for
SCIENTIFIC INFORMATION OFFICER
at the
Commonwealth Bureau of Nutrition,
Rowett Research Institute,
Bucksburn, Aberdeen AB2 9SB.

Duties: The scrutiny of the scientific literature, selection of papers and preparation of abstracts in concise English for publication in *Nutrition Abstracts and Reviews*.

Qualifications: An appropriate degree or its equivalent in agriculture or a related biological science. A reading knowledge of a European language is required and preference will be given to a candidate with ability in a Slav language or languages. The ability to write clear concise English is essential.

Salary: In the scale £2,839 to £5,448 (currently under review) plus a compensatory allowance (taxable but not superannuable) of 3½% to offset personal contribution to CAB Superannuation Scheme. Starting salary according to qualifications, experience and age. Promotion to higher scales on merit.

Application forms and full particulars from Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN. Closing date for applications 6th August, 1979.

2577(A)

THE UNIVERSITY OF MANCHESTER
TECHNICIAN (GRADE 5)
DEPARTMENT OF SURGERY
Withington Hospital

required to work in multi-disciplinary laboratory at the University Hospital of South Manchester, in the University Department of Surgery. The Department's research is in gastroenterology, haemodynamics and computing.

Applicants should have HNC, degree or equivalent qualification, preferably in Physics. Salary scale £3,474 to £4,056 pa.

Applications should be sent to Professor R A Sellwood, Department of Surgery, University Hospital of South Manchester, Nell Lane, West Didsbury, Manchester M20 8LR. 2608(A)

HERIOT-WATT UNIVERSITY RICCARTON
MARINE SCIENCE UNIT
INSTITUTE OF OFFSHORE ENGINEERING
RESEARCH ASSOCIATE

Applications are invited for the abov post. The successful applicant woul join a team investigating marin benthic populations unde programmes supported by industri contract and research grants.

Applicants should have an Honou degree in Marine Biology, Biology c Zoology with an interest in marin invertebrates.

Salary scale £3,689 to £5,321 p (under review).

Application forms and furthe particulars are available from the Staf Officer, Chambers Street, Edinburg EH1 1HX.

Informal enquiries for furthe details may be made direct to Miss J Appelbee, Marine Science Unit, Te No 031 449 5111.

2571(A)

MANCHESTER AREA HEALTH AUTHORITY (T CENTRAL DISTRICT
RESEARCH SCIENTIST

University Department of Clin Haematology, Manchester Ro Infirmary. The successful applicant have extensive experience protein/organic chemistry and b scientist of exceptional abilities who match the requirements of this se research post attached to the Su Regional Haemophilia Centre.

The aims of the post are to enhance academic and practical development haemostatic research with special refere to the biochemistry of Factor VII relation to function.

Minimal requirements are 1st-2nd c honours degree, F.I.M.L.S. or equiva and ideally a number of years prac laboratory experience. Appointmen Chief Medical Laboratory Scien Officer £5,472 to £6,192 or Se Scientific Officer £5,451 to £6,837. F salaries under review.

Further information from Mr K H Clinical Haematology, 061 273 3 Applications with curriculum vitae references to Dr I W Delamore at the ab address by 14th September 1979.

2576(A

Head of Toxicology

Continental Europe to c.£25,000 + benefits

This is an attractive and challenging appointment in a leading international company with a considerable research involvement in ethical pharmaceuticals.

The post is unusual in that the Toxicology Department concentrates on preliminary safety studies for new drugs, and then follows up—in-house—any unusual or unexpected responses which have been observed in the more routine and longer-term studies, which are contracted out.

The Department comprises some six graduates and a strong supporting staff. In addition to his/her managerial responsibilities for the effective running of the Department, the successful candidate will be directly involved in:

- Maintenance of a strong working relationship with contract research organisations in the UK and Europe, including regular liaison visits.
- Keeping abreast of developments in toxicology, regulatory and GLP requirements.
- Shaping research policy as a member of the Research Management Group.

The person we seek for this appointment will probably be in his or her 30s, and must have several years' broadly based experience in the toxicity testing of pharmaceuticals, in a senior position either within industry or in contract research. In addition, good management, planning and communication skills are of paramount importance.

Existing linguistic ability—other than in English—is not called for: English is widely spoken in the company and there are an increasing number of English employees. Applicants should, however, welcome the opportunity to broaden their experience by living on the Continent and learning another language.

The starting remuneration level will be around £25,000 (according to qualifications and experience) which, together with the other benefits of service, should provide a standard of living equivalent to about £17,500 in the UK. Generous removal expenses will be paid, including provision of a substantial tax free allowance to help settling into a new home.

Please write in confidence for an application form, or telephone if you would like to discuss the appointment further before applying:

Talentmark
Leaders in Health Care Recruitment

James A Edwards, Talentmark Limited
King House, 5-11 Westbourne Grove,
London W2 4UA. 01-229 2266 (24 hours).

2593A

BEATSON INSTITUTE FOR CANCER RESEARCH
Glasgow

POST DOCTORAL RESEARCH FELLOW

pplications are invited from post-ctoral scientists to collaborate on a oject involving a new approach to the lation and study of erythroleukaemia-ducing viruses in the mouse. This MRC oject will be associated with an ablished group involved in the analysis transformation and differentiation. iis position will provide ample portunity for gaining experience in cell d molecular biology and making ogress in an exciting area of research. chnical assistance will be provided.
The appointment is for a period of three ars from October 1979 with an initial ary of up to £5,129 on the University search Grade 1A, for someone with the propriate experience and qualifications. pplications enclosing a curriculum vitae ould be sent to Dr I B Pragnell from om further information can be gained. 2631(A)

UNIVERSITY OF DUNDEE

pplications, from candidates with interests in th biology and mathematics and with Honours gree qualifications in one or other of these lds, are invited for appointment as a

RESEARCH ASSISTANT

work with Dr I H M Smart in the Department of atomy on a project involving mathematical delling of the generation of cell populations in mammalian brain.
The appointment is financed from an external nt and is available for up to three years at a ry of £3,689 (to be reviewed in October 1979). pplications by curriculum vitae, quoting rence EST/64/79J and giving the names of referees, should be sent as soon as possible to Secretary, The University, Dundee DD1 N. 2566(A)

UNIVERSITY OF BRISTOL
SCHOOL OF CHEMISTRY, ORGANIC GEOCHEMISTRY UNIT

RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant (Grade 1B) to assist in the application and development of computerised gas chromatography-mass spectrometry and related techniques to the analysis of organic compounds in sediments and petroleums. Instrumentation includes Finnigan 4000, MS 30 and CH-7 spectrometers interfaced to an INCOS 2300 data system. Applicants should have a qualification in chemistry or physics and an interest in instrumentation. Previous experience in mass spectrometry and/or gas chromatography would be an advantage.
This post is funded by the Natural Environment Research Council (starting salary £3689 - £4232 per annum).
Please send applications with details and the names of two referees to Professor G. Eglinton, University of Bristol, School of Chemistry, Cantock's Close, Bristol BS8 1TS. 2490(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF VETERINARY PHYSIOLOGY AND PHARMACOLOGY

Applications are invited for the post of Lecturer in the Department of Veterinary Physiology and Pharmacology.
Initial salary on the scale £4,323 to £8,452 per annum.
Applications, together with the names of three referees, should be received not later than 9th August, 1979, by the Registrar, The University, P O Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/702/N. 2570(A)

CROP PHYSIOLOGIST

The Centro Internacional de Agricultura Tropical (CIAT), an international agricultural research center based in Colombia, South America, has an active program of crop research in *Phaseolus* species with emphasis on *P. vulgaris*. An interdisciplinary team concentrates its activities on developing new technology for this crop, principally for Latin America, but with increasing emphasis outside of the Western Hemisphere. Applications are invited to fill the position of Crop Physiologist within the team. The physiologist has responsibility for identifying physiological limits to yield and adaptation and in the screening of germplasm for characters likely to lead to breeding progress. Physiological research has been conducted for over four years and a strong base has already been established. The applicant should have a PhD in crop physiology and experience in an active crop improvement program. A working knowledge of the Spanish language would be preferred. The position is located at CIAT headquarters in Cali, Colombia.
A letter of application and curriculum vitae with names of three referees should be forwarded to: Dr Douglas R. Laing, Director for Crops Research, CIAT, Apartado Aéreo 6713, Cali, Colombia. Further information available on request. Applications must be sent to arrive by September 30. W244(A)

ANIMAL TECHNICIAN

A vacancy exists for an animal technician in the Cardiothoracic Research Laboratories at the Cardiothoracic Institute. Applicant should have A.I.A.T. Salary on Animal Technician Scale £2,883 to £3,192 plus LW.
Apply to the Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP stating age, qualifications and experience and giving the names of two referees. 2590(A)

UNIVERSITY OF EDINBURGH
Mitochondrial Genome Expression

POSTDOCTORAL RESEARCH FELLOW

required to join a group led by Dr C J Leaver working on mitochondrial genome expression during plant development. Previous experience in the field of mitochondrial biogenesis or function together with an interest in membrane protein isolation and purification would be an advantage but not a necessity. The successful candidate will also be required to use various techniques involved in nucleic acid isolation and *in vitro* translation already in use in the laboratory.
This post is supported by the SRC and is available from 1st October 1979 for three years but a suitable applicant may start at a later date. Salary on the 1A Scale for research staff, plus USS benefits.
Applications with curriculum vitae and naming two referees should be sent to Dr C J Leaver, Department of Botany, The King's Buildings, Mayfield Road, Edinburgh EH9 3JH, Scotland, as soon as possible. Please quote reference 5037. 2599(A)

TECHNICIAN Grade 3, required to assist in research on the actions of catecholamines on liver and muscle cell membranes. A biological background is essential and experience of one or more of the following techniques would be an advantage: organ bath pharmacology, electrophysiological recording, cell culture. The post offers the opportunity to learn a wide range of techniques. Salary in range £3,455 to £3,860 inclusive of London Weighting. Five weeks' annual paid holiday plus statutory and customary days giving one week at Christmas and Easter. Application form from Personnel Officer (Technical Staff FE11) University College London, Gower St WC1E 6BT. 2626(A)

Royal Observatory, Edinburgh

HIGHER SCIENTIFIC OFFICERS

(INFRARED ASTRONOMERS)

There are vacancies at the Royal Observatory, Edinburgh for astronomers experienced in infrared techniques. The successful applicants will become members of the UK Infrared Telescope Unit (UKIRT), one of the three National Facilities run by the Royal Observatory, the others being the UK Schmidt Telescope in Australia and the COSMOS Measuring Machine in Edinburgh.

Initially, the successful candidates will be allocated to the support group to monitor the construction of common-user instruments for UKIRT and maintain contacts between instrument builders, the UK astronomical community and the Unit in Hawaii. Both short term visits and postings of about three years to Hawaii are likely to be involved in the longer term.

The successful candidates will be expected to spend half their time on astronomical research, for which there are excellent facilities in Edinburgh. Applicants should have good degrees in physics or astronomy, extensive experience of relevant astronomical observing and instrumentation, and either a PhD or evidence of independent astronomical research.

Because the telescope is situated at high altitude a special medical examination is given to all members of the UKIRT operating team. Success in that examination will be a pre-requisite for appointment to this post.

Salary will be in the range £4,101 to £5,448 (under review) depending on age and experience.

Further details and application forms from the Personnel Officer, Royal Observatory, Blackford Hill, Edinburgh EH9 3HJ. Tel: 031 667 3321.

CLOSING DATE: 2 AUGUST 1979. 2605(A)

CSIRO AUSTRALIA

Research Scientist
Division of Protein Chemistry
Melbourne

CSIRO has a broad charter for research into primary and secondary industry area. The Organization has approximately 7,000 employees — 2,400 of whom are research and professional scientists located in Divisions and Sections throughout Australia.

FIELD: *Biochemistry*

GENERAL: The Division has a staff of over 120, approximately half of whom are professional. The Division's Research Programme includes a group, working on Hide, Skin and Leather research, which has close ties with the Leather Industry.

DUTIES: To study the effect on the properties of hides, skins and leather produced by changes at the molecular level, either naturally occurring or externally induced, in the nature of the collagenous and other components of the hide and skin.

QUALIFICATIONS: A PhD with a biochemistry background. Experience in protein chemistry and/or hide and skin properties an advantage.

SALARY: Research Scientist/Senior Research Scientist $A15,422 to $A22,405 pa.

TENURE: Indefinite with superannuation.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 462/447 should reach The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 18th August, 1979.

Applications in USA and Canada should be sent to The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, NW, Washington DC 20036, USA. 2610(A)

CHAIRMAN
of the
DEPARTMENT OF PHYSIOLOGY
WAYNE STATE UNIVERSITY
SCHOOL OF MEDICINE

Creative and energetic leader to assume the chair of this large and diverse department July 1, 1980. More than 20 faculty members, large and modern research and teaching facilities. Applicants should have an established and productive research record, experience in teaching and administration, to be able to assume responsibility for the medical, allied medical and graduate teaching programmes of the department. Sex, race, religion or national origin will not be factors in the selection process.

Interested persons should reply by August 1st 1979 to:

Dr Bernard H. Marks,
Department of Pharmacology,
Wayne State University,
School of Medicine,
Detroit, Michigan 48201.

W227(A)

UNIVERSITY OF MANCHESTER

EXPERIMENTAL OFFICER IN PHYSICS

Applications invited from graduates in Physics or Computer Science, or others with appropriate experience, for this post to co-ordinate and develop software on a network of mini-computers, and data aquisition systems connected to the SRC computer network. The systems are at present being installed and are supported by the SRC and the University. (This post, however, is established on University funds and not by a fixed term SRC grant). The person appointed will liaise directly with SRC computer personnel and staff of the Physics Department. Applicants should have experience in computing, preferably with PDP11 systems, and be keen to develop with the job and broaden their experience in the rapidly developing field of computer networks and on-line computer systems. Salary scale £4,333 to £7,521 pa, USS.

Details and application forms (returnable by August 3rd) from the Registrar, The University, Manchester M13 9PL. Quote ref: 172/79/Na.

2615(A)

UNIVERSITY OF BRISTOL
DEPARTMENT OF THEORETICAL CHEMISTRY

Theoretical studies of Electron-molecule collisions (Dissociative recombination processes)

Applications are invited for a

Science Research Council-supported Post-Doctoral Research Assistant

to work on theoretical calculations of electron-molecule collision processes of the type $e + AB^+ \rightarrow AB^* \rightarrow A + B$, with particular emphasis upon non-adiabatic (curve crossing) effects. The project is initially funded for 21 to 23 months (depending upon initial salary), with prospect of further extension. The work will also include co-operation with Professor P.G. Burke's research group at Daresbury Laboratory.

Applicants should write as soon as possible to Dr J Gerratt, Department of Theoretical Chemistry, University of Bristol, Bristol BS8 1TS, enclosing curriculum vitae and names and addresses of two referees. 2596(A)

SCOTT POLAR RESEARCH INSTITUTE
University of Cambridge

RESEARCH ASSISTANT ANTARCTIC GEOPHYSICS

The Scott Polar Research Institute ha completed glaciological and geophysica surveys over 50% of ice-covered Antarctic (7.5 M km^2). It is intended to consolida the scientific results of this work in a majo map and text folio.

We seek a research assistant for minimum period of two years to tak responsibility for compilation of materi for this folio including, where necessar some original analysis of data. Candidate should have a good Honours Degree in Physical or Earth Science subject (Physic Geophysics, Geology etc.). In additio experience in computer data-manageme and cartography would be advantageou Salary conforms to University age-relate pay scales (eg 25 years £4,505 [unde review]).

Applications, accompanied by fu curriculum vitae and names of two refere should be sent to The Director, Scott Pol Research Institute, Lensfield Roa Cambridge CB2 1ER (0223-66499).

2587(A)

EUROPEAN JOURNAL OF BIOCHEMISTRY

Applications are invited from graduates in biochemistry, PhD preferably, for the post of

EDITORIAL SECRETARY

at the journal's office in Liège.

Salary will be around £5,800 net per annum, or more according to special experience. Applicants should preferably be nationals of the member states of the European Economic Community.

Applications, which should include the name of at least one referee and complete curriculum vitae, should be sent as soon as possible to Professor Claude Liébecq, 69/054 Boulevard de la Constitution, B-4020 Liège, Belgium.

2533(A)

BIOCHEMIST AND BIOPHYSICIST

Postdoctoral positions available immediately to investigate (1) regulation and mechanism of gene expression, (2) nucleaic acid-protein interactions.

Send c.v. and 3 reference letters to Professor C.W. Wu, Dept of Biochemistry, Albert Einstein College of Medicine, 1300 Morris Park Ave., Bronx, NY 10461. An equal opportunity employer. W238(A)

LIPOPROTEIN BIOCHEMIST

UTAH

one year postdoctoral on lipoproteins solid-liquid interfaces. Some backgrou with complement and immunoglobuli desirable. Contact J.D. Andrade, Dept. Bioengineering, University of Utah, Sa Lake City, Utah 84112. (801) 581-850 Position available September 1, 1979. A Equal Opportunity/Affirmative Actic Employer. W239(A)

START A UNIQUE PHARMACEUTICAL PLANT

A major factor in the fight against the diseases of poverty in rural Bangladesh is the steady supply at low cost of essential drugs and medicines. Expensive imported products are available to a favoured few in urban areas.

Last year the World Health Organisation encouraged the creation of in-country pharmaceutical production units as one solution. That hope is now turning to reality at a community health project 22 miles from Dacca.

We have been asked to find two pharmacists — one for quality control, the other for planning and production — and a maintenance engineer to help establish and run a pharmaceutical production unit. It aims to supply 20% of the drug requirement for rural Bangladesh.

You will need at least three years pharmaceutical production experience and the ability to pass on your skills to local staff. You will receive the local salary, free accommodation and travel to and from Bangladesh.

Write to Jane Mackay or Ed Murray, Room M, Voluntary Service Overseas, 9 Belgrave Square, London SW1X 8PW. 2583(A)

SANDOZ RESEARCH INSTITUTE
in Vienna, Austria

is one of three international research centres of the Swiss based pharmaceutical company.

In the **Immunobiology Department** of this institute a senior staff position for a

VIROLOGIST

is available.

The person we are seeking should have a PhD or equivalent degree with specialization in animal or medical virology. Experience in molecular virology and virus genetics would be of advantage.

The successful candidate will join an active research group working on **influenza and other respiratory viruses**. The work will lead to practical applications in the field of viral vaccines, but emphasis is laid on basic research as well.

A knowledge of German is not a prerequisite, but would be advantageous.

Research facilities and working conditions are excellent. Salary will be negotiable, commensurate with experience and qualifications. Other benefits include a non-contributory pension scheme and full assistance toward moving expenses.

Please send curriculum vitae, list of publications and the names of referees to

SANDOZ

Dr. N. Zacherl, Personnel Manager,
SANDOZ Forschungsinstitut Wien,
Brunner Straße 59
A-1235 Vienna, Austria W242(A)

SIMON FRASER UNIVERSITY
Burnaby, British Columbia
Canada
DEPARTMENT OF BIOLOGICAL SCIENCES
ENTOMOLOGIST

pplications are invited for a tenure-track sition as an Assistant Professor in tomology. The successful applicant will expected to develop a strong research ogram and to participate in the teaching ogram at both the undergraduate and aduate level including the Master of Pest anagement Program. Candidates must ve a PhD degree in entomology or a ated subject. The position is available mediately, subject to budgetary proval. The initial appointment will be a period of 2 years, renewable. The ary scale is under revision; the current ary base for the Assistant Professor rank $18,604 per annum.

Applications should include an up-to-e curriculum vitae, a brief statement of earch interests and goals, and reprints of olished research. Applicants should uest a confidential assessment of their earch and teaching ability from three erees, to be forwarded directly to M Mackauer, Chairman, Dept of ological Sciences, Simon Fraser iversity, Burnaby, BC, Canada, A 1S6. Deadline for receipt of lications is 15 September 1979 or when ition filled. W240(A)

UNIVERSITY OF OXFORD
DEPARTMENT OF CLINICAL BIOCHEMISTRY
TECHNICIAN

iired for research into regulation of the uvate dehydrogenase complex. The t is available initially for two years from ober 1. Applicants should have a degree iochemistry (or a related subject) or ess suitable laboratory experience. ting salary up to £4,047 per annum. pplications including the names of two rees to Professor P. J. Randle, artment of Clinical Biochemistry, n Radcliffe Hospital, Headington, rd, OX3 9DU. 2578(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF ZOOLOGY
FIELD TECHNICIAN (GRADE 3)

The post involves assistance with field studies, especially on freshwater fish, although laboratory work is also involved. Candidates must be willing to work long hours, often in adverse weather conditions. Experience with small boats and engines and an interest in fish an advantage.

Candidates must hold current driving licence, possess ONC or equivalent and have three years laboratory experience.

Salary in range £2,931 to £3,336 p.a.

Application forms may be obtained from The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/699/N. 2560(A)

UNIVERSITY OF GLASGOW
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the position of Postdoctoral Research Assistant to study "The Translational Control of Rat Skeletal Muscle Protein Synthesis by Insulin". The appointment, which is from October 1st 1979, will be supported by the British Diabetic Association for a maximum of three years, and the starting salary will be £4,333 per annum on Range 1A of the salary scales for Research and Analogous Staff. The appropriate superannuation scheme will apply.

Applications, with curriculum vitae and the names of two referees should be sent to Dr D P Leader, Department of Biochemistry, University of Glasgow G12 8QQ. In reply please quote Ref No 4488M. 2563(A)

Royal Observatory, Edinburgh
PROFESSIONAL AND TECHNOLOGY OFFICER
GRADE 1

The Technology Unit at the Royal Observatory has a vacancy for an engineer at PTO I level. The Unit is responsible for research, development and manufacture of a wide range of instrumentation for the National Facilities run by the Observatory, which include the 1.2 metre Schmidt Telescope in Australia, the 3.8 metre Infrared Telescope in Hawaii and the COSMOS Measuring Machine at Edinburgh.

The successful candidate will be responsible for applications of infrared and optical solid-state and vidicon-type detectors to the recording of extremely low levels of radiation. Initially he/she will be involved in the development and construction of a cooled 10 micron array spectrometer, operating with As doped silicon diodes.

The applicant should be a fully qualified engineer; possession of an advanced degree may be an advantage. Applicants will be required to describe successful results with solid-state or vidicon-type systems which they have developed.

Starting salary will be in the range £5,739 to £7,064 depending on age and experience. A non-contributory superannuation scheme is included.

SRC

Further details and application forms from The Personnel Officer, Royal Observatory, Blackford Hill, Edinburgh EH9 3HJ. Tel: 031 667 3321.
CLOSING DATE: 2 AUGUST 1979.

2604(A)

Overseas Opportunities in Agriculture & Research

The Kuwait Institute for Scientific Research, a rapidly expanding institute for applied science and technology, is seeking professionals interested in challenging careers in agriculture and research.

Range Specialist

You should have an M.SC in range management; a minimum of three years' experience in range improvement practices and sheep production; and a knowledge of range machinery and equipment.

Researcher

You should have a Ph. D. in agronomy or equivalent; a minimum of four years' experience in forage production management of pasture harvested crops and nurseries; and academic training or experience in arid region development. Knowledge of irrigation systems is desirable.

Kuwait Institute offers attractive salaries commensurate withh qualifications and experience, furnished housing, liberal fringe benefits including round trip air tickets, and free medical benefits.

Please airmail your resume to the Personnel Manager, Kuwait Institute for Scientific Research, P.O. Box 24485, Safat, Kuwait, State of Kuwait, no later than one month from the date of this publication.

Kuwait Institute for Scientific Research

W234(A)

TECHNICIAN

A Technician is required to assist in a programme of work on neurotoxicity. Training in biochemistry is essential but some experience in physiological techniques would be an advantage. Qualifications: Degree HNC or equivalent. Salary on scale of £3,261 to £4,680 plus London Weighting of £354.

Apply in writing giving curriculum vitae to Mr V. H. Parker, Toxicology Unit, MRC Laboratories, Woodmansterne Road, Carshalton, Surrey.

MRC Medical Research Council

2598(A)

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOLOGICAL SCIENCES

There is a vacancy for a

RESEARCH ASSISTANT
(Plant Physiology)

to work with Dr Jonathan Weyers on a project concerned with stomatal movements during water stress. The work will involve the isolation of leaf epidermis cell protoplasts and investigation of their reactions to the plant hormone abscissic acid.

The appointment, supported by an SRC grant, is available for three years from 1 October 1979 at an initial salary (under review) of £3,775. The successful applicant may be able to register for a PhD.

Applications (by curriculum vitae containing the names of two referees and quoting REF: EST/73/79J) should be lodged as soon as possible with The Secretary, The University, Dundee, DD1 4HN. 2573(A)

UMIST
LECTURER IN ORGANIC CHEMISTRY

Applications are invited from candidates of either sex for a post of Lecturer in Organic Chemistry. The Department of Chemistry has a full teaching programme in Organic Chemistry for Honours and Ordinary degrees of the University of Manchester, and has excellent analytical, spectroscopic and synthesis services for research. Applicants should have an interest in the biological applications of organic synthesis.

Salary will be according to age and experience on the scale £4,232 to £8,452. The appointment will begin as soon as possible.

Application forms and further particulars can be obtained from the Registrar, UMIST, P O Box 88, Manchester M60 1QD, and should be returned by 30th September 1979 at the latest. Please quote reference CH/132/AI. 2559(A)

UNIVERSITY OF NEW SOUTH WALES
Sydney, Australia

National Health and Medical Research Council (NH & MRC) SENIOR RESEARCH OFFICER
SCHOOL OF PHYSIOLOGY & PHARMACOLOGY

Applications are invited for appointment to a postdoctoral position commencing October 1979, to work on synaptic effects of anaesthetics using voltage clamp and noise analysis techniques. Position available initially to 31 December 1980.

Further information is available from Professor Peter W. Gage, School of Physiology and Pharmacology, University of New South Wales, Kensington, NSW Australia 2033. Salary per annum: $A15,786 range $A20,737. Commencing salary according to qualifications and experience. Applications should be submitted immediately.

Information about method of application can be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 2602(A)

PRE AND POSTDOCTORAL POSITIONS

are available for individuals with microbiology background for studies on the protein synthesising system with special emphasis on ribosomes — topography, biogenesis and function. Teaching opportunities are available. Reply with résumé to: Dr Bruce H. Sells, Professor and Director, Laboratories of Molecular Biology, Faculty of Medicine, Health Sciences Centre, Memorial University of Newfoundland, St John's, Newfoundland A1B 3V6, Canada. W235(A)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
University of London

TECHNICIAN

Two Technicians required to work in Department of Biochemistry. Salary on Whitley Council scale according to age and experience. Further details and application forms from the School Secretary, R.F.H.S.M., 8 Hunter Street, London WC1N 1BP, or tel. 01 837 5385 ext. 54. Closing date 3rd August, 1979. 2555(A)

THE UNIVERSITY OF MANCHESTER

TECHNICIAN (GRADE 3)
DEPARTMENT OF MEDICINE
Hope Hospital

The successful applicant will work under the direction of Dr D C Anderson, Senior Lecturer in Medicine (Endocrinology) on a research project examining the action and interaction of hormones and vitamin D metabolites in bone. This involves *in vivo* and *in vitro* experiments and techniques including tissue and cell culture, subcellular fractionation, light and electron microscopy and receptor and saturation analysis techniques. Previous experience in some or all of these techniques is desirable but not essential. It is hoped that the successful applicant would want to become actively involved in the research. Starting date will be mid-September. Salary scale £2,931 to £3,336 pa.

Applications should be addressed to Dr D C Anderson, Department of Medicine, Hope Hospital, Eccles Old Road, Salford, M6 8HD. 2607(A)

BIRKBECK COLLEGE (University of London)
DEPARTMENT OF ZOOLOGY

MSc IN COMPARATIVE PHYSIOLOGY

A two-year part-time evening course suitable for zoology graduates wishing to specialise in the comparative aspects of the adaptations of animals to their environment. Topics covered include: osmotic and ionic regulation; respiratory & circulatory physiology; endocrinology; neurophysiology. Students are introduced to a wide range of modern physiological techniques. For further details contact the Departmental Secretary, Department of Zoology, Birkbeck College, Malet Street, London WC1E 7HX. 2581(A)

UNIVERSITY OF MANCHESTER
DEPARTMENT OF PHYSICS

Applications are invited for the post of

LECTURER

in the Department of Physics. The successful candidate will be expected to carry out experimental work within the Atomic, Molecular and Polymer Physics Group of the Department. Some preference will be given to candidates intending to pursue studies in the field of coherent interactions or laser spectroscopy, but candidates having other interests which are related to those of the Group will also be considered. The appointment is from October 1st, 1979 or as soon as possible thereafter at an initial salary normally within the range £4,33 to £5,199 p.a. Further particulars and application forms are obtainable from the Registrar, the University, Manchester M13 9PL, to whom completed forms should be returned by August 3rd. Quote ref. 147/79/N. 2526(A)

UNIVERSITY OF BRISTOL
DEPARTMENT OF ZOOLOGY

POSTDOCTORAL POSITIC NEUROPHYSIOLOGY

To join a group investigating spinal c neurones co-ordinating swimming amphibian embryos. Experience v intracellular microelectrode recording, horseradish peroxidaze technique computer modelling of neuronal netwo is needed.

The post can start after 1st October, I at a salary of £4,382 pa (subject to revis from the 1st October, 1979). Applicati with a curriculum vitae and two referee Dr Alan Roberts, Department of Zoolc University of Bristol, Woodland Rc Bristol BS8 1UG, as soon as possible. 2575(A

WELSH NATIONAL SCHOOL OF MEDICINE
(Univeristy of Wales)
DEPARTMENT OF MEDICINE
RESEARCH OFFICER

Applications are invited for the above appointment with Dr R Marks, Reader and Consultant in Dermatology, Welsh National School of Medicine, on a collaborative project with the Department of Biochemistry at University College, Cardiff to identify serum component(s) of possible importance in wound healing. The work will involve assay systems, organ culture and histometric techniques.

Candidates should have a degree in Biochemistry or other biological discipline and experience with histological procedures and tissue-culture systems would be advantageous.

The appointment, which will be for one year in the first instance (renewable for a second year) is financed by a grant from the Medical Research Council. Starting salary up to £4,232 per annum (under review).

Applications in the form of a curriculum vitae, with the names and addresses of two referees, should be sent to the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff 3 weeks from the date of appearance of this advertisement (quoting ref. No. M6/53). Further information from Dr R Marks (0222/755944 ext. 2885). 2552(A)

PORTSMOUTH POLYTECHNIC
DEPARTMENT OF BIOLOGICAL SCIENCES
RESEARCH ASSISTANT

Applications are invited from final year students and graduates wishing to undertake research for a higher degree.

Title: Ecological studies of enterotoxin production by staphylococcal isolates from meat. Supervisor: Dr E May. Salary: £2,589 to £2,643 pa (under review). Contract is initially for 2 years.

Application forms and further particulars obtainable from the Staff Office, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ, to whom completed applications should be returned by 3rd August, 1979. Please quote reference number B45. 2624(A)

POSTDOCTORAL POSITION

Available September 1979, for research on the transport and metabolism of purines by malaria infected red cells. Experience in nucleic acid chemistry and/or transport preferred.

Send résumé and three references to: Dr Irwin W. Sherman, Department of Biology, University of California, Riverside, Calif. 92521. An Equal Opportunity/Affirmative Action Employer. W241(A)

POSTDOCTORAL FELLOW

An immediate opening is available for a recent PhD biochemist with experience in 1) *in vitro* translational systems and/or 2) purification and characterization of phosphatases and phosphokinases. The person chosen will have the opportunity to interact with several interdisciplinary groups and the fellowship will run for two to three years. All interested candidates should send a resumé and three names of referees to:

Dr George Thomas
Friedrich Miescher-Institut
P O Box 273
CH-4002 Basel,
Switzerland W230(A)

UNIVERSITY COLLEGE LONDON
DEPARTMENT OF PHARMACOLOGY
TECHNICIAN VACANCIES

Technician Grade 5 required to work on MRC supported programme of work on peripheral synaptic mechanisms. The post requires some experience of electrophysiological techniques and will involve the construction, testing and maintenance of electrical equipment. The laboratory is equipped with a PDP 11/40 computer and some knowledge of this type of equipment will be an advantage. Salary in range £3,998 to £4,106 inclusive of London Weighting.

Technician Grade 3 required for biochemical and pharmacological work on peripheral synaptic mechanisms, supported by the Medical Research Council. The programme involves about six scientific staff and a variety of experimental techniques, including tissue culture, microelectrode recording, radiolabelling experiments and biological assays. Salary in range £3,455 to £3,533 inclusive of London Weighting. Five weeks' annual paid holiday plus statutory and customary days giving one week at Christmas and Easter. Application form from Personnel Officer (Technical Staff FE10) University College London, Gower St, WC1E 6BT. 2627(A)

THE UNIVERSITY OF MANCHESTER
TECHNICIAN (GRADE 5)
DEPARTMENT OF DIAGNOSTIC RADIOLOGY

The Department has three radiographic suites, one of which contains the EMI Whole Body Scanner. Current research is concerned with the development of new non-invasive techniques employing conventional radiographic equipment and computed tomographic scanning. Minor surgical procedures, isotope techniques and animal care are important aspects of the work. The post offers considerable scope for initiative. Radiographic experience is unnecessary but previous animal experience would be desirable. Salary scale £3,474 to £4,056 pa.

Applications should be addressed to Professor Ian Isherwood, Department of Diagnostic Radiology, Stopford Medical School, University of Manchester, Oxford Road, Manchester M13 9PT. 2606(A)

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMISTRY
RESEARCH TECHNICIAN

A vacancy exists for a technician to join a research group led by Dr Philip Cohen in the above Department and engaged in a study of the role of protein phosphorylation in the nervous and hormonal control of intermediary metabolism.

The appointment is financed from an MRC programme grant and is from 1 October 1979. Candidates with an appropriate formal qualification (eg ONC Biochemistry) and three years' relevant practical experience will be eligible for appointment at a salary of up to £3,009 per annum. The possibility of a suitable candidate being appointed at either a more senior or more junior grade is not excluded.

Application forms are available from and should be returned as soon as possible to the Establishments Office, The University, Dundee DD1 4HN. Please quote Reference EST/141/79J. 2565(A)

CSIRO AUSTRALIA

Postdoctoral Research Fellow
Division of Fisheries & Oceanography
Perth

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of who are research and professional scientists — located in Divisions and Sections throughout Australia.

FIELD: *Marine Population Ecologist.*

GENERAL: The Division is Australia's principal marine research institution with more than 80 scientists investigating the physical, chemical and biological features, including fisheries, of the oceans around Australia. Headquarters of the Division are at Sydney with regional laboratories in Perth, Brisbane and a field laboratory at Karumba. The appointee will be located in Perth.

DUTIES: To develop a programme that would integrate with ongoing studies of food web dynamics, rock lobster distribution and larval settlement, macroalgal and seagrass growth and distribution on limestone and coral reefs along the coast of Western Australia. Research interests should be in population dynamics and field experimentation. Experience in nearshore and coral reef ecosystems would be advantageous as would taxonomic knowledge of macroalgae on invertebrates.

QUALIFICATIONS: A PhD or equivalent qualifications in a relevant field, preferably with experience in a marine environment. Ability to work efficiently at sea is essential.

SALARY: Research Scientist or Senior Research Scientist $A15,422 to $A22,405.

TENURE: Fixed term appointment of 3 to 5 years depending upon experience.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 320/632 should reach The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 18th August 1979.

Applications in USA and Canada should be sent to The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, NW, Washington DC 20036, USA. 2611(A)

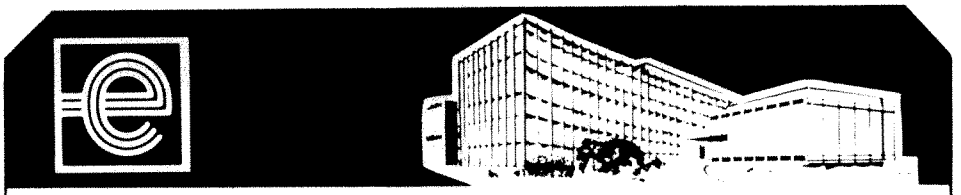
OXFORD UNIVERSITY
Sir William Dunn School of Pathology
NUCLEIC ACID BIOCHEMIST

Applications are invited for a post-doctoral research position, funded by the Cancer Research Campaign. The research concerns the preparation and transcription of superhelical templates derived from the nuclear DNA of human cells. Experience in enzyme purification (for the preparation of DNA gyrase and the relaxing enzyme) or the assay of specific transcripts is desirable, but not essential.

The appointment, starting as soon as possible after 1st October 1979, is likely to be for 2 years. The salary will be at an appropriate point on the University 1A scale, £4,232 to £7,145.

Applications, including curriculum vitae and the names and addresses of 2 referees, should be sent as soon as possible to Dr P R Cook, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE. 2625(A)

UNIVERSITY OF OXFORD IN ASSOCIATION WITH ST. HUGH'S COLLEGE
LECTURERSHIP IN ASTRONOMY



Applications are invited, from men and women candidates, for a University Lecturership in Astronomy, in the Department of Astrophysics, to be filled from 1 January 1980 or as soon as possible thereafter.

Preference will be given to applicants with a broad knowledge of astrophysics whose research interests lie in the field of optical astronomy (including the ultraviolet and infrared regions).

The stipend will be according to age on the scale £4,232 to £9,000 (under review) with superannuation.

The lecturership may be held with a tutorial fellowship in physics at St. Hugh's College and a linked lecturership at St. Edmund Hall. Applicants should state whether they wish to be considered for the college posts.

Further details of the university and college posts may be obtained from Professor D.E. Blackwell, Department of Astrophysics, South Park Road, Oxford, OX1 3RQ, to whom applications (one typed copy) should be sent before 15 October, 1979. Applications should contain a statement of qualifications, a list of publications, an outline of a proposed research programme and the names of three referees. 2595(A)

TECHNICAL OFFICER
(COMPUTER APPLICATIONS)
Applied Physics Division

MATHEMATICS SECTION

The successful candidate will join a team in the Mathematics Section whose work covers a range of research areas in addition to providing a mathematical service within CERL. He/she will work closely with Research Officers engaged on a number of problems for which numerical and computation solution plays a large and important role. In addition he/she would contribute to the mathematical and computational service provided by the Section.

Applicants should ideally possess an HNC or equivalent qualification and at least two years experience of computer programming. The duties of the post require ideally a good understanding of mathematics and numerical analysis, together with a knowledge of a range of computer languages and modern programming techniques.

The appointment will be made within a salary range of £4110 to £6035 (currently under review) plus a payment under a Self-Financing Productivity Scheme of between £10 and £15 per month.

The Laboratories are situated in a pleasant part of Surrey and offer attractive Conditions of Service, and facilities for the total of 800 Research and Support Staff engaged in a broad spectrum of research into the materials, technologies and plant performance problems of the Central Electricity Generating Board.

Application forms are obtainable from the Head of Personnel Development & Services, Central Electricity Research Laboratories, Kelvin Avenue, Leatherhead, Surrey KT22 7SE or telephone Leatherhead 74488 Ext. 363, quoting reference number **RL/37/N.** Closing date is: **Friday 3rd August 1979.**

CENTRAL ELECTRICITY RESEARCH LABORATORIES

2642(A)

BRUNEL UNIVERSITY

SCHOOL OF CHEMISTRY

POSTDOCTORAL RESEARCH

CATALYST PREPARATION AND CHARACTERISATION

Applications are invited from suitably qualified candidates for a postdoctoral research appointment on a 2 year SRC-supported programme which will be available from 1 October 1979 or as soon as possible thereafter. The programme, which is supervised by Dr Paul A. Sermon, concerns novel methods of preparing and characterising supported catalysts. A wide variety of techniques is available for catalyst characterisation and testing, including S EM, XPS, YRD and adsorptive and catalytic probes and spectroscopic techniques. Starting salary would be £4,952 per annum but this is under review. Candidates should send a detailed curriculum vitae to Establishment Secretary, Brunel University, Uxbridge, Middx UB8 3PH by 1 August 1979.

2641(A)

UNIVERSITY OF CAMBRIDGE

CAVENDISH LABORATORY

The Metal Physics Group in the Cavendish Laboratory wish to fill a new post of Senior Assistant in Research. The post is tenable for up to five years, and is renewable after that period; the salary is in the range £5,048 to £6,627 per annum (under review) and carries U.S.S. benefits.

The main duties of the post are to undertake the development of new techniques of electron microscopy and analysis and the application of these techniques to solid state physics and to materials science, including the design and commissioning of instrumentation such as electron spectrometers, electron and photon detectors and related electronics.

The successful applicant will have responsibility for research projects and the training of research students as well as the pursuit of his own research.

Applications should be sent to the Secretary, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE before 1 September, accompanied by the names of two referees and a curriculum vitae. 2591(A)

IMPERIAL COLLEGE

POSTDOCTORAL RESEARCH BIOCHEMIST

Applications are invited for an SRC financed research assistantship to continue a project on ergot alkaloid biosynthesis using a fungal cell-free enzyme system. The post is available for one year from 1 October 1979 at a salary of £4,762 (under review). Candidates should write to Dr P G Mantle, Biochemistry Department, Imperial College, London SW7 2AZ. 2632(A)

BIRKBECK COLLEGE
(University of London)

DEPARTMENT OF ZOOLOGY

MSc IN ENTOMOLOGY

This two-year, part-time evening course is designed primarily for entomologists but also allows teachers and others to extend their training in a scientific discipline and to become conversant with the tools of current research. Topics covered include: sensory and neuromuscular physiology, respiratory physiology, osmotic and ionic regulation, insect genetics, taxonomy and economic entomology. For further details contact the Departmental Secretary, Department of Zoology, Birkbeck College, Malet Street, London, WC1E 7HX.

2582(A)

UNIVERSITY OF NAIROBI
(Kenya)

Applications are invited for the following posts in the

DEPARTMENT OF FORESTRY:

LECTURER IN FOREST PROTECTION

Applicants should preferably be holders of a PhD in Forestry with specialisation in Forest Pathology. Additional training in Wildlife Management and Fire Contro will be advantageous. The appointee wil participate in teaching undergraduate anc post-graduate courses and will undertake research in his/her field of specialisation.

LECTURER IN FOREST ECOLOGY

Applicants should preferably be holders of a PhD in Forestry or Botany with emphasis on forest ecology. Training and research experience in arid land afforestation, quantitative classificatior of forest types and regional dendrology will be advantageous. The appointee wil participate in teaching undergraduate anc post-graduate courses and undertake research in his/her field of specialisation

LECTURER IN WOOD UTILISATION

Applicants should preferably be holder of a PhD in Forestry with specialisatior in identification, structure and propertie of common softwoods and hardwoods The appointee will participate in teachin undergraduate and post-graduate course and will undertake research in his/he field of specialisation.

Salary scale: K£2016 to K£3312 p.a (K£1 = £1.22 sterling). The Britis Government may supplement salaries i range £4278 to £4818 p.a. (sterling) fo married appointees and £2730 to £3156 p.a (sterling) for single appointees (reviewe annually and normally free from tax) asn provide children's education allowance and holiday visit passages. Famil passages; FSSU or SSSF; non contributory medical scheme; subsidise housing/housing allowance.

Detailed applications (2 copies) wit curriculum vitae and naming 3 referees t be send direct to Registrar (Recruitmer and Training), University of Nairob P.O. Box 30197, Nairobi, kenya by 2 August 1979. Applicants resident in th UK should also send one copy to Inte University Council, 90/91 Tottenhar Court Road, London, W1P 0DT. Furthe details may be obtained from eithe address. 2640(A)

UNIVERSITY OF CAMBRIDGE

CAVENDISH LABORATORY

Applications are invited from suitab qualified physicists, chemists metallurgists for a post doctoral resear post jointly funded by ICI and the SR under the Collaborative Award Schem The work is concerned with the structu and composition of very highly dispers supported metal catalysts of enhanc activity and will provide an insight into t application of advanced resear techniques to systems of direct industr interest. Experience in electron microsco and related techniques is required.

The appointment will be for two ye from October 1979, based in Cambrid but with about 10% of the period at Corporate Laboratory of ICI at Runco Salary is in the range £4,282 to £5,048 annum (under review). Applicatio should be addressed to the Secreta Cavendish Laboratory, Madingley Ro Cambridge CB3 0HE. 2592(A)

UNIVERSITY OF NAIROBI
(Kenya)

Applications are invited for (4 posts)

SENIOR LECTURESHIPS
in the
DEPARTMENT OF ZOOLOGY

The specialisms required are as follows: (a) medical entomologist; (b) vertebrate ecologist; (c) fish biologist; and (d) physiologist, cell biologist, entomologist or parasitologist.

Applicants must have considerable post-doctoral experience in teaching and/or research. Where relevant, tropical and especially African experience will be an advantage. The appointees will be expected to teach both undergraduate and graduate students and to conduct their own research.

Salary scale: K£2988 to K£3984 p.a. (K£1 = £1.22 sterling). The British Government may supplement salaries by £5430 p.a. (sterling) for married apointees and £3648 p.a. (sterling) for single appointees (reviewed annually and normally free from tax) and provide children's education allowances and holiday visit passages. Family passages; SSSF or FSSU; non-contributory medical scheme; subsidised housing/housing allowance.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar (recruitment and Training), University of Nairobi, P.O. Box 30197, Nairobi, Kenya by 21 August 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 2638(A)

SENIOR TECHNICIAN/ TECHNICIAN

required to assist the Biological Hazard Safety Officer on all matters relating to Safety in the Fund's Laboratories. Microbiological and virological experience essential.

Level of appointment will depend on qualifications and experience. Salary range £3,600 to £6,100. For further information and an application form please telephone Miss S M Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2 on 242 0200 ext. 305. 2585(A)

UNIVERSITY COLLEGE LONDON
DEPARTMENT OF PHARMACOLOGY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a two-year, MRC-supported appointment to work on the effects of catecholamines and adenine nucleotides on the membranes of liver, fat and smooth muscle cells. Electrophysiological or biochemical experience required.

Applications with curriculum vitae and the names of two referees to Dr D H Jenkinson, Dept of Pharmacology, University College London, Gower St, London WC1E 6BT from whom further details may be obtained. Closing date 9th August 1979. 2580(A)

AUSTRALIAN NATIONAL UNIVERSITY
Research School of Physical Sciences
DEPARTMENT OF SOLID STATE PHYSICS

FELLOW/ SENIOR FELLOW

The University wishes to make a tenured appointment at the level of Fellow or Senior Fellow to extend and enhance research in the Department of Solid State Physics, Research School of Physical Sciences. The Department is well equipped for studies in all aspects of solid state spectroscopy (EPR, Mossbauer, ultraviolet, visible and infra-red) and in cryogenics and thermal properties of condensed matter. There are excellent facilities for materials preparation and supporting mechanical and electrical workshops. The senior solid state experimentalist appointed will have broad interest in an area of research central to modern solid state physics, and will be expected to make appropriate use of existing facilities with, if necessary, some modest providision for additional specialised equipment. An ability to foster links with researchers elsewhere in the University, and with other Australian solid state physicists will be important.

Closing date: 31 August 1979.

Salaries: Salary will be in accordance with qualifications and experience within the range: Senior Fellow $A24,686 to $A28,773; Fellow $A18,401 to $A24,652, Present exchange rate is $A1 = 52p.

Term of Appointment: Fellow/Senior Fellow — five years in the first instance with the possibility of reappointment to age 65.

Other Conditions: Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with finding accommodation is provided for an appointee from outside Canberra. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should first obtain further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 2637(A)

TECHNICIAN/ RESEARCH OFFICER

to assist our Chemistry Laboratory with projects involving the relationships between chemical structure and cancer producing activity. Degree/HNC. Experience of synthetic organic chemistry preferred. Salary range £3,600 to £5,250. For application form write or telephone Miss S M Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2 on 242 0200 ext 305. 2618(A)

BIOCHEMICAL VIROLOGY

A junior or senior postdoctoral position is available to study biochemical aspects of influenza virus replication and antigenic variation in influenza viruses. Successful candidates must have strong backgrounds in biochemistry. Send curriculum vitae and a statement of career goals to Dr R G Webster, Division of Virology, St Jude Children's Research Hospital, P O Box 318, Memphis, Tn. 38101. An Equal Opportunity/Affirmative Action Employer. W236(A)

FELLOWSHIPS

UNIVERSITY OF YORK

ARCHAEOZOOLOGICAL RESEARCH FELLOWSHIP

Applications are invited for this post in the Environmental Archaeology Unit of the Department of Biology. The appointment is for three years from 1 October 1979 or later, on Range 1A, and is to study multivariate changes in bones of pigs and cattle from the Anglo-Scandinavian to early medieval period in York.

Three copies of applications and curricula vitae, naming three referees, should be sent by 1 September 1979 to the Registrar, University of York, Heslington, York, YO1 5DD, from whom further particulars may be obtained. Please quote reference number 11/6109. 2630(E)

DEPARTMENT OF EDUCATION
Dublin

POST-DOCTORAL RESEARCH FELLOWSHIPS 1979-80

The closing date for the receipt of applications for post-doctoral research fellowships 1979-80 awarded by the Department of Education has been extended to 20 July, 1979.

Research fellowships in Science (excluding Medical and Social Science) and Engineering may be awarded to sufficiently meritorious candidates. Fellowships will be tenable for a period of two years at any of the following institutions: University College, Dublin; University College, Cork; University College, Galway; Trinity College, Dublin; An Foras Talúntais (The Agricultural Institute); The Institute for Industrial Research and Standards.

Applicants should hold the degree of PhD or have equivalent research or industrial experience. Candidates should not be more than 30 years of age but preferably under 28 years of age.

Further particulars of the scheme including application forms may be obtained from the Department of Education, Headquarters (Section 3), Marlboro Street, Dublin 1. Applications for fellowships should be forwarded so as to arrive at the Department of Education not later than 5 pm on 20 July, 1979. 2568(E)

UNIVERSITY OF DUBLIN
Trinity College

POST-DOCTORAL FELLOWSHIP IN BIO-ORGANIC CHEMISTRY

Applications are invited for a post-doctoral fellowship, commencing 1st October 1979, for work with Dr D. H. Grayson of the Department of Chemistry on the mechanism of enzymic conversion of chorismic acid into anthranilic acid.

The appointment, which is supported by the national board for science and technology, would be particularly suitable for an organic chemist with some experience of biochemical systems and/or radio-tracer techniques. This position is up to a total of three years, at a salary of £3,837 — £3,994 — 4,153 pa (currently under review).

Applications, giving details of qualifications and experience to date, and naming two referees, should be submitted to:

The Establishment Officer,
Staff Office,
West Theatre,
Trinity College,
Dublin 2.

Who will receive completed applications up to Friday, 17th August, 1979. 2567(E)

UNIVERSITY OF EXETER
DEPARTMENT OF CHEMISTRY

Studies of Iron-Sulphur Peptide Clusters

Applications are invited for two Science Research Council sponsored

POSTDOCTORAL RESEARCH FELLOWSHIPS

to work in collaboration with Dr Brian Ridge on the synthesis and physico-chemical study of iron-sulphur peptide clusters related to the ferredoxins. (Previous experience in either the synthesis of peptides or the handling of extremely air sensitive materials would be an advantage.)

The appointments are for a maximum of three years, but will be made for one year in the first instance, commencing 1st October 1979. Salary (1A Scale) will be in the range £4,333 to £4,910 pa (under review) plus superannuation.

Applications, with full curriculum vitae and the names and addresses of two referees, should be sent to Dr B Ridge, Department of Chemistry, University of Exeter, Exeter EX4 4QD to reach him by 31st August 1979. 2616(E)

STUDENTSHIPS and FELLOWSHIPS

THE HANNAH RESEARCH INSTITUTE

For Studies Relating to the Production and Utilization of Milk.

RESEARCH STUDENTSHIP

Applications are invited for Graduates holding a first or upper second class honours degree in either Chemistry, Biochemistry, Physiology, Agricultural Sciences or related disciplines, for appointment to an Agricultural Research Council Postgraduate Studentship tenable for 3 years from October 1979 leading to a PhD.

Particulars of the topics offered for research and details of the conditions of the award may be obtained from:

The Secretary
The Hannah Research Institute
Ayr. KA6 5HL
Tel. Prestwick 76013

to whom applications, giving full ciriculum vitae, and the names and addresses of two academic referees, should be sent by: 10th August 1979.

2633(F)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF CHEMISTRY

POST-DOCTORAL RESEARCH FELLOWSHIP IN ORGANIC CHEMISTRY

Applications are invited for a post-doctoral research fellowship, supported by the SRC, to work in collaboration with Dr G.B. Gill. The programme involves an exploratory study of the catalysis of Ene reactions, particularly with a view to developing procedures of preparative value — notably in the area of terpenoid synthesis.

Applicants should have a good background and a general interest in synthetic organic chemistry. The appointment is tenable for 2 years, and is available from 1 October, 1979. Starting salary (1A scale) in the range £3,975 to £4,505 p.a., plus U.S.S.

Applications, including a curriculum vitae and the names of two academic referees should be addressed, as soon as possible, to: The Staff Appointments Officer, The University of Nottingham, University Park, Nottingham NG7 2RD, quoting Ref. No. 705. 2556(E)

UNIVERSITY COLLEGE OF SWANSEA

CASE Studentship

for Medical Physics

Applications are invited from suitably qualified graduates, or students expecting to graduate this year, for an

SRC RESEARCH STUDENTSHIP

associated with a research project to investigate the feasibility of developing an *in-vivo* technique for the determination of Beryllium in human organs. The research is part of a collaborative programme being undertaken by the Department of Physics in the University and the Department of Medical Physics in the adjacent hospital, and will involve work in both establishments. The student will be encouraged to register for the PhD degree of the University of Wales.

Further details and application forms from Professor J Dutton, Department of Physics, University College of Swansea, Singleton Park, Swansea, SA2 8PP, Tel (0792) 25678, Ext 390. 2594(F)

UNIVERSITY OF OXFORD

DYSON PERRINS (ORGANIC CHEMISTRY) LABORATORY

Applications are invited for a postdoctoral fellowship to work on the synthesis of novel chiral phosphines and their application to asymmetric catalysis. The post is in

RESEARCH ASSISTANT GRADE 1A

on the scale £4,232 to £4,776 p.a. according to age and experience, with membership of U.S.S., and is supported by S.R.C. for a period of up to 2 years. The starting date is October 1st, 1979 or as soon as possible thereafter.

Applications with curiculum vitae and the names of two referees should be sent as soon as possible to Dr J M Brown, Dyson Perrins Laboratory, South Park Road, Oxford. OX1 3QY. 2636(E)

STUDENTSHIPS

UNIVERSITY OF BRITISH COLUMBIA

Vancouver, Canada

DEPARTMENT OF PHYSIOLOGY

Applications are invited for a research studentship available from September 1st, 1979. The successful candidate will be expected to work in the field of the reflex control of the cardiovascular and respiratory systems and to register for a higher degree. Applicants should have a First Class or Upper Second Class Honours degree in a biomedical subject.

The studentship will be valued at $6,500 per annum and may be supplemented by additional teaching duties.

Applications including a curriculum vitae and the names of two referees should be sent as soon as possible to Dr J R Ledsome, Department of Physiology, UBC, Vancouver, BC, Canada V6T 1W5. W243(F)

UNIVERSITY OF BRADFORD

SRC CASE RESEARCH STUDENTSHIP IN STRUCTURAL CHEMISTRY

Applications are invited from good honours degree graduates or equivalent to read for a PhD on a joint investigation with B.S.C. (Chemicals) Ltd, into thermally induced structural changes in coal-tar pitch and their components by chromatography, N.M.R. spectroscopy and other techniques. Further details and application forms may be obtained from Dr D W Jones, School of Chemistry, University of Bradford, West Yorkshire BD7 1DP. (0274-33466 ext 288 or 289). Ref RS/DWJ/X. 2561(F)

Southampton THE UNIVERSITY

SOLAR CELL THEORY Post-doctoral SRC Fellowship

Applications are invited for the above post-doctoral post which is available from 1 September 1979, and is suitable for appropriately interested mathematicians, physicists or engineers. Salary up to £4,505.

Applications giving the names of two referees should be sent to Professor P T Landsberg, Department of Mathematics, University of Southampton, Highfield, Southampton SO9 5NH, before 9 August 1979. Please quote ref: N. 2623(E)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF GENETICS

Applications are invited from men and women for a 3 year Postdoctoral Fellowship tenable 1 October 1979 or as soon as possible thereafter and funded by the SRC for work on the control of cell division in *Saccharomyces cerevisiae*. Applicants should either have experience in recombinant DNA techniques or in microbial genetics. Salary up to £4,910 a year on Range 1A.

Applications including curriculum vitae and names and addresses of two referees to Dr P Sudbery, Department of Genetics, The University, Sheffield S10 2TN as soon as possible. Quote Ref R341/G. 2617(E)

CITY OF BIRMINGHAM POLYTECHNIC

DEPARTMENT OF SCIENCE

SRC STUDENTSHIP IN ENZYMOLOGY

The research programme will involve an investigation of the physico-chemical properties and *in vivo* distribution of therapeutically important, stabilised, enzymes. Candidates should have or expect a good honours degree or equivalent in Biochemistry, Chemistry, Pharmacy or a related science. The appointee will be expected to register for a PhD degree (CNAA). The studentship is tenable for 3 years from 1st October 1979 (subject to confirmation). Informal enquiries may be made to Dr R L Foster (051 207 3581 ext 48).

Further details and application forms are available from Dr J M Hitchen, Head of Department of Science, City of Birmingham Polytechnic, Perry Barr, Birmingham B42 2SU Tel 021 356 6911. 2622(F)

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF CHEMISTRY

SRC-CASE RESEARCH STUDENTSHIP

Applications are invited for a three year SRC (CASE) Research Studentship to work on the effect of impurities on the mechanism of the interaction of nickel with carbon monoxide. The work will be supervised by Professor M.W. Roberts in collaboration with Inco Europe Ltd.

Applicants should hold or expect to hold at least an upper second class honours degree in chemistry.

Applications, with the names of two referees should be sent to Professor M.W. Roberts, Department of Chemistry, University College, P.O. Box 78, Cardiff CF1 1XL. Reference 1850. 2553(F)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF METALLURGY AND MATERIALS SCIENCE

SRC CASE and AERE HARWELL sponsored Research Studentships

Applications are invited from good honours (1st or 2(1)) graduates in Metallurgy/Materials Science or related Physical Sciences for 3 year sponsored research studentships tenable from October 1st 1979. The research projects are in the following areas.

(a) Structure and Embrittlement of Low Alloy Ferritic Steels (2 positions).

Research into the relation between microstructure, segregation of alloy and impurity elements to grain boundaries and susceptibility to intergranular fracture in ferritic steels used for power engineering structures in collaboration with AERE Harwell. Supervisors: Prof B L Eyre and Dr B C Edwards.

(b) Stress Corrosion Cracking in Aluminium Alloys.

Research into the relation between the atomic structure of grain boundaries and observed rates of intergranular stress corrosion in commercial aluminium alloys in collaboration with Alcan Industries. Supervisors: Dr R C Pond and Dr C Tuck.

(c) Light-ion Bombardment of Non-metallic Materials.

To investigate the effects of light, gas ion bombardment on the microstructure and surface of ceramic materials having potential for use in fusion reactors in collaboration with the Culham Laboratory. Supervisors: Dr D J Bacon and Dr K Erents.

(d) Studentships and projects are also available in other areas, viz. heat treatment of steels, computer simulation of crystal defects, development of composite materials, mechanical properties of metals, properties of cellular materials and the properties of bio-materials.

Applications should be received as soon as possible by the Registrar, The University, P O Box 147, Liverpool L69 3BX. Quote ref RV/703/N. 2569(F)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL RESEARCH FELLOWSHIP IN BIOENERGETICS

Applications are invited for a Research Fellowship to investigate the factors controlling the synthesis of ATP after short flash excitation of membranes isolated from the photosynthetic bacteria. The principle aim of this SRC-supported project is to determine the relationship between electron transport reactions through defined segments of the electron transport chain, the development of the electrochemical proton gradient and the extent and rate of ATP synthesis after single and multiple flashes.

The appointment is for three years commencing October 1979 (or as soon as possible thereafter) in the range (under review) £4,333 to £5,488 (from 1 October). Starting salary not expected to exceed £4,910 pa. Candidates should preferably have some previous experience in the field of mitochondrial, chloroplast or bacterial bioenergetics.

Applications, including a short curriculum vitae and the names of three academic referees should be sent by 10 August to Miss L. R. Heyes, Senate Registry, University of Birmingham PO Box 363, Birmingham B15 2TT Further details may be obtained from Dr. J. B. Jackson, Department of Biochemistry. Tel: 021-472 1301 Ext. 3113 2520(E)

THE HARTLEY FELLOWSHIPS of the UNIVERSITY OF SOUTHAMPTON

Applications are invited for three Fellowships normally tenable from 1 October 1980, for up to two years research, in any field for which facilities are available within the Faculties of Arts, Science, Engineering & Applied Science, Social Sciences, Law, Education, Medicine and Mathematical Studies.

Fellows will normally be appointed from persons of high promise whose records show evidence of capacity for original research, and who have up to five years post-doctoral experience or equivalent research record.

Salary will be related to age and experience and be within nationally agreed ranges for research staff in universities. (No provision for travel or removal expenses).

The closing date for applications for the 1980 competition is 1 November 1979.

Details and application forms from Mr E.D. Gordon, The University, Southampton SO9 5NH.

Please quote reference N. 2462(E)

UNIVERSITY OF WARWICK

POSTDOCTORAL RESEARCH FELLOW in Molecular Beam Scattering

Applications are invited for an SRC Postdoctoral Research Fellowship in the Department of Chemistry and Molecular Sciences to work on the investigation of simple ion molecule reactions using a crossed molecular beam apparatus in collaboration with Dr D M Hirst. Applicants should have experience in electronics, high vacuum work and preferably in molecular beams. The post, which is available immediately, will be for one year in the first instance. Salary on the Range 1A Scale £4,333 to £7,521 pa from 1st October, 1979. Application forms and further details from the Academic Registrar, University of Warwick, Coventry CV4 7AL. Ref No 50/A/79.

2614(E)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MICROBIOLOGY

POST-DOCTORAL RESEARCH FELLOWSHIP

Biochemist or chemical microbiologist needed to purify cell-wall components responsible for the resistance of gonococci to killing by human phagocytes. The project, which relates to a gonococcal vaccine, is supported by the Medical Research Council for three years from 1st October, 1979.

Salary will be in the Research Fellow 1A range £4,333 to £7,521, plus superannuation. Maximum starting salary will be £5,199. For further details apply to Professor H. Smith, Department of Microbiology.

Applications (3 copies) including full curriculum vitae and naming three referees should be sent to the Assistant Registrar, Science and Engineering, P O Box 363, University of Birmingham, Birmingham B15 2TT, by Monday 13th August, 1979. Please quote reference NM7. 2613(E)

UNIVERSITY OF STRATHCLYDE

Applications are invited for a

POSTDOCTORAL RESEARCH FELLOWSHIP IN ANALYTICAL CHEMISTRY in the DEPARTMENT OF PURE AND APPLIED SCIENCE

tenable for one year in the first instance, to work on the design and development of an automatic monitor for the measurement of beryllium metal in atmospheric dusts. Preference will be given to candidates with experience in atomic spectroscopy as the principal technique to be used will be carbon furnace atomic absorption spectrometry. The post is suitable for an experienced analytical chemist and will involve close liaison with colleagues working on methods of dust collection and on instrument design and production. The post is sponsored by the Atomic Weapons Research Establishment, Aldermaston, and will be under the supervision of Dr J M Ottaway.

Appointment will be on Range 1A of the national salary structure for research and analogous staff with a commencing salary from 1 October 1979 up to £6,066 per annum. Placing according to qualifications and experience. Superannuation benefit.

Written applications naming three referees (quoting R26/79) should be forwarded as soon as possible to Dr J M Ottaway, Department of Pure and Applied Chemistry, University of Strathclyde, Cathedral Street, Glasgow G1 1XL, from whom further information may be obtained.

2562(E)

QUEEN MARY COLLEGE University of London

CHEMISTRY DEPARTMENT

Applications are invited for a postdoctoral

RESEARCH FELLOWSHIP

on an SRC-Supported project to study magnetic anisotropy of polynuclear co-ordination compounds with Dr P Thornton. Appointment for 2 years from 1 October 1979, suitable for a chemist or chemical physicist with experience in magnetochemistry or other work with single crystals. Initial salary in range (under review) £4,835 to £5,412 pa (including London Allowance).

Please apply as soon as possible, giving age, qualifications, experience and names and addresses of 2 referees, to The Registrar,(N) Queen Mary College, Mile End Road, London E1 4NS. 2579(E)

QUEEN MARY COLLEGE (University of London)

CHEMISTRY DEPARTMENT

Applications are invited for an SRC-supported

Postdoctoral RESEARCH FELLOWSHIP

to work with Dr D. G. Buckley on the biosynthesis and synthesis of novel pyrrolylpolyene fungal pigments. Experience in the use of ^{13}C- and/or ^{14}C-labelled compounds an advantage. Appointment for two years from 1 October with initial salary in range (under review) £4835 to £5412 p.a. (including London Allowance).

Applications, with curriculum vitae and names and addresses of two referees, as soon as possible to The Registrar, (N) Queen Mary College, Mile End Road, London E1 4NS. 2639(E)

NUFFIELD FOUNDATION

ONE-YEAR SCIENCE RESEARCH FELLOWSHIPS

The Nuffield Foundation is offering to University Lecturers in Science (but not Mathematics) Departments a number of one-year research fellowships to be awarded competitively at the end of 1979 and to be held during the academic year 1980-81. The objective is to enable younger university lecturers to be freed from teaching and administrative duties for one academic year in the first instance; preference will therefore be given to applicants under the age of 40. Awards will cover the cost of replacement teaching and will include an allowance for research expenses.

The closing date is 15 October 1979 and further particulars may be had from the Director, Nuffield Foundation, Nuffield Lodge, Regent's Park, London NW1 4RS 2589(E)

ASSISTANTSHIPS

UNIVERSITY OF LONDON
ST BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE
and the
INSTITUTE OF NEUROLOGY

Applications are invited from good honours graduates in Biochemistry or related subjects for a

RESEARCH ASSISTANTSHIP

to undertake investigations into the metabolism of muscle mitochondria in both normal and diseased states. The successful candidate would be expected to register for a PhD degree.

The appointment is for three years from 1st October at an initial salary (under review) of £4,191 per annum including London weighting.

Applications, with c.v. and names of three referees, should be sent by 20th August to Dr J B Clark, Biochemistry Department, St Bartholomew's Hospital Medical College, Charterhouse Square, London EC1M 6BQ (Tel: 01-253 0661, ext 22). 2628(P)

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF BOTANY

RESEARCH ASSISTANTSHIP

Applications are invited for the post of research assistant to work on an IBM supported-project concerned with computer techniques for the recording and display of quaternary pollen analytical data. A degree in computer science, applied mathematics, or related subject is required; experience in numerical analysis of large data sets and of computer graphics is essential. Starting salary is in the range of £4,232 to £4,776 per annum plus USS. Appointment is for one year in the first instance, starting from October 1979, with the possibility of renewal for a further year.

Applications, with a curriculum vitae and names of two referees, should be sent to Dr H J B Birks, Botany School, Downing Street, Cambridge CB2 3EA by 10 August at the latest, from whom further particulars may be obtained. 2629(P)

UNIVERSITY OF GLASGOW

POSTDOCTORAL RESEARCH ASSISTANTSHIP IN SOLID STATE PHYSICS

Applications are invited for an SRC Postdoctoral Research Assistantship to work on a VG Microscope's HB5 Scanning Transmission Electron Microscope due to be delivered in early 1980. The proposed research covers a wide range of micro-analytical (energy dispersive X-rays spectroscopy, electron energy loss spectroscopy, microdiffraction) and novel imaging techniques. Experience in one or more of the following fields would be an advantage: electron microscopy, electronics, ultra high vacuum techniques, minicomputers.

The post is tenable from 1 October 1979 until 31 July 1982 with an initial salary on Range 1A of the Salary Scales for Research and Analogous Staff (£4,333 to £7,227 per annum). Superannuation benefits will apply.

Applications stating age, academic qualifications, research experience and the names of two referees should be submitted not later than 20th August, 1979 to Professor J. C. Gunn, Department of Natural Philosophy, University of Glasgow, Glasgow G12 8QQ, from whom further details of the research work of the Solid State Physics group may be obtained. In reply please quote Ref. No. 4488M. 2574(P)

UNIVERSITY OF DURHAM
DEPARTMENT OF PHYSICS

Applications are invited for one or more SRC funded

POSTDOCTORAL SENIOR RESEARCH ASSISTANTS

tenable for 2 years from 1 October 1979 to work with the COSMOLOGY group, whose main interest is in the formation and evolution of galaxies. There may also be opportunities to work with large telescopes. Extensive computer experience would be an advantage.

Initial salary in the range £4,333 to £4,910 on Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by 31 July 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE from whom further particulars may be obtained. 2554(P)

ELECTROPHORESIS
A state of the art report from Marine Colloids

aKem® Agarose is the preferred medium for electrophoresis

Marine Colloids is the world leader in agarose with more experience and more end-use-specific types of agarose than any other manufacturer. Tell us the properties you want and we'll supply the agarose you need. Ask for a copy of our catalog and price list.

elBond™ film is making glass plates obsolete

GelBond is Marine Colloids' tradename for the new transparent, flexible, specially-treated polyester film* to which freshly-prepared agarose, agar and polyacrylamide gels adhere and remain adhered during use. Its advantages are convenience, permanence and firm adhesion of the gels throughout drying, staining, destaining and storage. Try it once and you'll never go back to glass. Only Marine Colloids offers GelBond film. Ask for a copy of our GelBond bulletin and price list and free samples.

*Custom manufactured for Marine Colloids by the 3M Co.

oGel™ (No EEO) Agarose. A breakthrough in ISOELECTROFOCUSING

The IEF procedure separates and concentrates proteins on the basis of minute differences in their isoelectric points. Until recently, the application of the IEF technique in continuous media was limited to polyacrylamide gels despite their notorious limitations. With the advent of IsoGel, the many familiar advantages of agarose are now commercially available in a gel medium having no electroendosmosis ($-M_r$). In addition and perhaps most important is its capability of direct and immediate extraction and focusing of proteins from biopsy tissue. Ask for a copy of our new instruction manual which describes the Agarose Isoelectrofocusing technique and provides a recommended procedure for protein analysis.

or Serum Protein Analysis, GelBond™ film with SeaKem® Agarose fers superior resolution plus

World leaders in Clinical Chemistry now recognize the superiority of SeaKem Agarose and GelBond film over cellulose acetate for routine serum EP. They have come to prefer the convenience, reproducibility, greater yield of diagnostic information and sharp, permanent records provided by SeaKem and GelBond. [AGAROSE GEL ELECTROPHORESIS, submitted by J.-O. Jeppsson, C.-B. Laurell and B. Franzén, Department of Clinical Chemistry, Malmö General Hospital, Sweden, is now a proposed selected method of the ASCC (Clinical Chemistry Vol. 25, #4, 1979)]

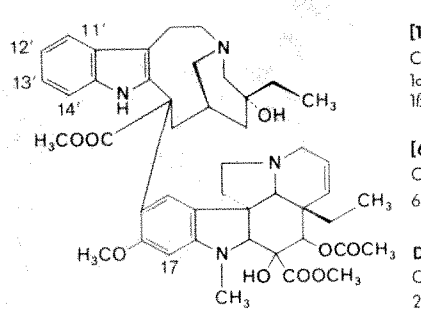
applied excellence

Advanced techniques in routine use at The Radiochemical Centre

Described below are just two examples of the many up-to-date techniques, which have been pioneered or applied for routine use at The Radiochemical Centre. These developments are part of our constant endeavour to maintain our position at the forefront of the specialised field of tracer methodology, so that we can continue our supply of radiochemicals of the highest quality and technical specifications.



Distribution of labelling in tritium compounds

Modern techniques for the production of tritiated compounds are more sophisticated than those used in the early days of tritium labelling, and produce compounds labelled in specific positions rather than generally labelled. Nevertheless, it is necessary for many tracer applications of tritium compounds to know the *precise* position and configuration of the tritium labels. Traditional chemical methods of doing this are tedious and time consuming and subject to considerable error, and so the routine supply of such information has until recently not been possible.

The Radiochemical Centre, in collaboration with the University of Surrey, has developed over the past eight years the technique of tritium nuclear magnetic resonance (tnmr) spectroscopy for this purpose. This method is much quicker and more accurate than the traditional chemical or biochemical methods for determining distribution of tritium labelling.

It is now used routinely to establish the distribution of tritium labelling produced by the usual methods of tritiation employed at The Radiochemical Centre. We supply accurate details as to the position and configuration of the tritium labels for an increasing number of our labelled compounds.

A number of examples are given below:

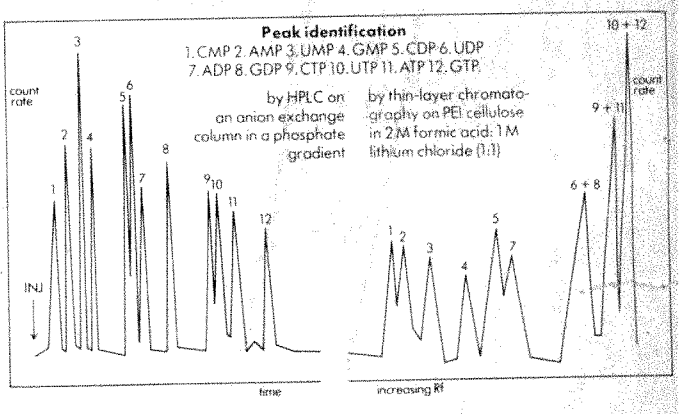
[1β, 2β(n)-^{3}H]TESTOSTERONE
Code TRK.162
1α ..... 5.9% 2α 8.2%
1β ..... 46.0% 2β 39.9%

[6-^{3}H]BENZO[a]PYRENE
Code TRK.501
6 ..... >95% 1 ..... <5%

D-[2-^{3}H]GLUCOSE
Code TRK.361
2(α) ..... 40% 2(β) 60%

[G-^{3}H]VINBLASTINE
Code TRK.507
17 ..... 44% 11' 8%
12,13 ..... 46% 14' 2%

L-[3,4(n)-^{3}H]VALINE
Code TRA/K.533
2 ..... 8% 4 ..... 64%
3 ..... 28%



High performance liquid chromatography (HPLC)

This relatively new development of column chromatography is carried out using high efficiency microparticulate column packings of closely defined size.

Chromatography is carried out under pressure to ensure good flow rates and reduce diffusion of separated compounds. Dead volumes are kept to an absolute minimum. The result is that many separations can be carried out more quickly and with better resolution than with previously used chromatographic methods such as thin-layer chromatography or conventional column chromatography.

Work aimed at developing the applications of this method to radiolabelled compound separations is still in progress, but The Radiochemical Centre is already using the technique in many of its production processes, and in analytical applications. The result is purer compounds for the customer and greater efficiency of working.

The example illustrated below illustrates the clear superiority of HPLC when used as an analytical tool. The mixture used comprised the tritium labelled mono-, di- and triphosphates of adenosine, cytidine, guanosine and uridine, and all are clearly separated in the HPLC system.

Protein methylation and bacterial chemotaxis

wanted

an arginine specific protease

caught

one male mouse!

known to be the best source of an arginine specific protease from the submaxillaris glands, available under Cat. No. 269 590.

In addition we present:

Aminopeptidase M	Clostripain	Pepsin
Bromelain	Collagenase	Protease (nonspecific) from Streptomyces griseus
Carboxypeptidase A	Dispase	Proteinase K
Carboxypeptidase B	Elastase	Pyroglutamate aminopeptidase
Carboxypeptidase Y	Ficin	Subtilisin
Cathepsin C	Leucine aminopeptidase	Thermolysin
Chymotrypsin A_4	Papain	Trypsin

Cover picture

Demonstration of bacterial chemotaxis showing two mutants plated on agar containing two attractants. Each strain can utilise only one of the attractants and each consumes the attractant it can use, forming a gradient and an expanding ring. The rings expand independently across the agar. Evidence for the involvement of protein methylation in bacterial chemotaxis is reviewed on p. 279.

UNRESTRAINED CREATIVITY

The ALZET® osmotic minipump ... control complements chemistry in the quest for specificity.

Since Ehrlich's time, chemistry has been the dominant creative force in the quest for specificity in the action for drugs. Yet true specificity is elusive, and even the hormones show undesirable and unsafe actions when their concentrations in blood or tissues are uncontrolled. The physiology of hormonal secretory control systems teaches how control has complemented chemistry in nature's quest for specificity and continuity in hormonal action.

The ALZET® osmotic minipump now gives you unprecedented, round-the-clock control for one and two weeks over the entry of drugs or hormones into the bloodstream of unrestrained lab animals. With the incredible minipumps, you can attain gland-like control, allowing you to optimize both the specificity and the continuity of action of the agents you use in your research.

Creativity in applying the principle of control to complement chemistry is yours for the doing. Examples of such creativity are illustrated in the rapidly expanding Alzet® osmotic minipump product bibliography. May we include your abstract or paper reporting work based on minipump use? For a copy of the bibliography, or to order, call the following toll-free number: 800/227-9953. In California and Hawaii, call collect: 415/494-5067.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

ANNOUNCEMENTS xiii

WANTED: NEW PRODUCTS AND TECHNOLOGIES

Health Care:

- ☐ Pharmaceuticals
- ☐ Diagnostics
- ☐ Devices
- ☐ Other prescription and non-prescription products

Toiletries:

- ☐ Oral hygiene
- ☐ Skin care
- ☐ Hair Care
- ☐ Other toiletries and grooming aids

Here is a major opportunity for product and technology owners to sell or license their innovations to leading marketers in the U.S., Europe and Japan.

A group of such companies has commissioned PRI to search for such developments on their behalf. Wanted are marketed products, products under development, new formulations, ingredients, manufacturing know-how, distribution rights, dispensing and applicator systems, etc.

You Pay Us Nothing

The sponsoring companies are paying PRI to conduct this search. It is entirely free to you. (However, PRI retains the sole right to decide what to include, or not include, in our report to the companies.)

Patented or patent-applied-for products are preferred, but innovations of all kinds will be considered.

The report, a book entitled "The Licensing and Acquisition Source Book," will be delivered to the companies later this year. If your innovation or product interests one or more companies, they will contact you directly to discuss purchase or license. (In a previous search, 61% of the innovations reported in the "Source Book" were the subject of active inquiry by the companies.)

Who We Are

For a statement of our credentials, plus the procedure you should follow to take advantage of this opportunity, please write to PRI now. You should make *no* disclosures at this time, except for *issued* patents—or, if the product is marketed and hence non-confidential, you may send a sample.

Send nothing you regard as confidential! Don't miss this opportunity. Write in today.

Attention Marketers. *For information on the Licensing and Acquisition Source Book and other PRI services, write to the address below.*

PRODUCT RESOURCES INTERNATIONAL, INC.

How much coal?

There is not the slightest doubt that an immense amount of coal resides under the British Isles. Onshore there are at present many healthy coalfields, and new ones such as Selby, Belvoir and Coventry-Kenilworth could make substantial additions; further down the line the Oxfordshire field could possibly outshine anything that has gone before. Offshore, there is ample evidence of rich fields at great depth below the North Sea. Why then should anyone disagree with the claims of the National Coal Board (NCB), repeated recently in large advertisements, that 'we have proven coal resources to last for at least another three hundred years'? Is it not just an academic quibble to ask for more scrupulous definitions of the term 'proven resources'?

A wide range of geological opinion thinks not. The Flowers' Commission on Energy and the Environment has recently been turning its attention to coal, and has received some tart comments about NCB publicity — this is a dispute which has simmered for many years. Terminology in the assessment of minerals is, if you will pardon the phrase, a minefield. But common practice is to distinguish, first, between reserves and resources. The term 'resource' covers all material about which something is known, although information may be exceedingly thin either about the extent of the resource or about ways in which it could be exploited. And, not surprisingly, a 'resource' includes a large amount of material which will on further research, turn out to be unexploitable because of, for instance, environmental or social unacceptability. So one thing the NCB does not have is a 'proven resource' — a contradiction in terms.

What the board is actually talking about if it uses the word 'proven' is 'reserves': materials that have been mapped out sufficiently well that they can be the subject of mining by known methods. The most important of the several definitions of reserve is the 'workable' or 'operating' reserve — the amount of coal that can be mined economically according to present-day detailed assessment. This figure, like all reserves, may fall if the price of coal were to drop, and may fall just as easily as rise if new equipment were installed that required thicker seams or was sensitive to faulting. In 1973 the NCB's assessment of current workable reserves amounted to 3.9 billion tonnes according to the board's then Chief Geologist (G. Armstrong, *Phil. Trans. roy. Soc.*, **276**, 439-452 (1974)). This is enough for around 30 years at present rates of consumption. Since then a vigorous programme of exploration and assessment has inched the workable reserves up to 6 billion tonnes.

How, then, does the NCB get its figure of 300 years — equivalent to a workable reserve of 45 billion tonnes? Geologists outside the NCB claim that the board tends to be a law unto itself and there is a severe shortage of coal geologists outside the board's embrace able to provide an independent estimate. But one thing does seem to be clear — that the 45 billion tonnes is bound to contain a vast amount of coal that is no more than rough guesswork at present. It seems that the figure arises not from the building up of detailed estimates from individual fields but from an estimate of what could be the total coal (shallower than 4,000 feet and in seams greater than 2 feet thick) under Britain; the total is then cut down to reflect the fraction of this coal which, on past experience, has actually been brought to the surface. The picture of a coal industry progressively and steadily working its way through the production of 45 billion tonnes over the next 300 years is thus, at best, no more than a giant extrapolation; at worst it could be totally deceptive.

But does it matter? Shouldn't the NCB be allowed a certain amount of exuberance concerning its future? In private, yes; there is little harm in a bit of optimism about an energy source that Britain has somewhat neglected in the recent past. But continued public statements on the subject could have a very harmful effect, as investment in energy technology and the development of other types of energy sources is bound to be distorted once the NCB's point of view gains general currency, particularly amongst politicians.

Most prudent energy industries like to look ahead at least fifteen years, and whilst NCB is talking about figures such as 6 billion tonnes it is being equally prudent. In making guesses at much larger figures and calling them 'proven resources' it is surely taking quite unnecessary liberties. □

Developing world 'a permanent desert for research'

Six countries account for 85% of the world's total spending on research and development. This monopoly is a major feature of global inequality, writes **Anil Agarwal**

MOST countries in the world today form a permanent research desert, the remaining few forming a small number of R&D oases. This is the conclusion of Dr Jan Annerstedt of Roskilde University in Denmark who has conducted a detailed survey of R&D activities across the world. Six nations (USA, Soviet Union, Japan, West Germany, France and the United Kingdom) employ nearly 70% of the world's R&D manpower and spend nearly 85% of R&D funds. The USA and Soviet Union account for more than half of the world's total R&D expenditure. Together, these six countries spend a quarter of every R&D dollar in the world for military purposes.

This "concentration of research and experimental development to a small number of highly industrialised countries is one of the major features of global inequality", says Dr Annerstedt in his paper on the present global distribution of R&D resources, recently released by the Vienna Institute for Development. Developing countries account for nearly 70% of the world's population but they contribute less than 3% of the world's R&D expenditures, and about 13% of the world's R&D scientists and engineers.

As far as the developing countries are concerned, this distribution of world R&D activity has remained almost unchanged. Based on a sample of countries for which R&D statistics existed in 1963 — 1964 (excluding most socialist and developing countries), the United Nations had estimated that developing countries accounted for only 2% of the world's R&D expenditure. The US was responsible for 70% and other market economies for the remaining 28%. Using this same sample of countries, Dr Annerstedt finds that their research expenditures have increased from less than $30 billion in 1963-64 to over $60 billion in 1973. But the share of developing countries has only increased from 2% to 2.8%. The share of the US has dropped from 70% to 50.7%, while that of the other developed market economies has increased dramatically from 28% to 46.5%.

Annerstedt's own survey of world R&D expenditures in 1973, however, also covers socialist countries in Europe and Asia and several more developing countries. He estimates that the world spent a total of about $96.4 billion on R&D in 1973. Developing countries accounted for 2.9% of this sum. The rest was spent by rich countries, primarily in Europe and North America.

Annerstedt's data shows that within the Third World, South and Central American countries were spending most money on R&D in comparison to their populations — about 33% of the Third World's R&D expenditure on 11% of its population. Asian countries (excluding Japan, Israel and Turkey) spent over 50% of Third World R&D expenditure but they contain over 75% of the Third World's population. African countries contain 14% of the population and spend about 10% of the R&D resources.

The distribution of R&D manpower is more in favour of the Third World than the distribution of R&D expenditures. Annerstedt's study shows that developing countries had more than 12% of the world's scientists and engineers engaged in R&D, or 290,000 of the world's 2.3 million researchers. Three quarters of the Third World's R&D workers were active in Asia, about 10% in Africa (excluding South Africa) and the rest in Latin American countries. The latter, however, had the highest number of researchers per million economically active persons (EAP) that is, 460 R&D workers per million EAP.

But if all R&D personnel are included (that is, technicians and other supporting staff), then the Third World fares even better. The Third World, and in particular Asian organisations, have a higher number of technicians and supporting staff per researcher than the developed countries have.

Annerstedt believes that the distribution of overall scientific and technical manpower may be changing fast in the favour of the Third World. Educational expansion is faster in the developing than in the developed countries. In 1973, there were 4.6 million students graduating from universities and other institutions of higher learning all over the world. 23% of the third level graduates were from the developing countries (not considering those who were foreign students in developed countries and excluding China because of lack of reliable statistics). Among the twenty countries in the world with the highest total number of university graduates were seven developing countries: India, Brazil, the Philippines, Bangladesh, Democratic Republic of Korea, Egypt and Pakistan. The Philippines, Lebanon, Argentina, Venezuela and Chile had 54,500 to 48,050 third level students per million economically active persons. When compared in this way, they were only

behind the US, Canada, Israel and New Zealand.

In terms of sheer numbers, India claims to possess the world's third largest scientific and technical manpower, only behind the US and USSR. India had at the end of 1977, 2.3 million people with qualifications in science, engineering, medicine and agriculture. In April 1976, 54,000 professional scientists were engaged in R&D work supported by some 40,000 technicians and another 50,000 people engaged in administrative and non-technical jobs.

China too has a vast stock of scientific and technical manpower. Aqueil Ahmed of the Administrative Staff College of India believes that India and China should be alternatively either third or fourth in international comparisons of scientific manpower. The eight-year science and technology plan (1978-85) recently announced by the Chinese government aims to increase the number of professional R&D scientists to 800,000 (compared to the total Third World complement of 288,000 in 1973).

But the fact that developing countries spend so little (2.9%) on R&D even though they have a much larger proportion of scientists (12.6%), means that each R&D worker in the developing countries gets few resources to work with. Many scientists have, in fact, emigrated from the Third World to the developed countries complaining that they do not enjoy adequate support. □

Military research the big spender

MORE than a third of the global research and development budget is spent on military and space research, and less than a tenth on health and agricultural research, according to a report published this week by the Worldwatch Institute in Washington. In addition, over 95% of R&D funds are spent in the industrialised countries; yet these contain less than 20% of the global population.

The report, written by Colin Norman, a senior research fellow at the institute, covers ground similar to the Annerstedt report (see left). Norman says that imbalance in research priorities — both between subject areas, and in meeting the needs of the rich rather than the poor — urgently need to be reordered. It points out, for example, that the US Government is expected to spend about $670 million in 1979 on research and development aimed at improving the productivity of American agriculture; and that this sum far exceeds the agricultural R&D expenditures of all the developing countries put together.

"The worldwide distribution of R&D capacity closely matches the global distribution of economic power," says the report. The disparity applied both to financial and manpower resources. It had been calculated, for example, that during the early 1970s developing countries had about 300 scientists working on R&D for every million workers, compared to the developed countries, which had 4,000 scientists for every million workers.

The report says that the world's research and development priorities need to be reordered by, for example, channelling more money into neglected research areas, new research organisation and Third World laboratories, as well as encouraging the increasing expenditure by industrialised countries on research appropriate to developing country needs, and stimulating co-operative research efforts between the developing countries themselves.

However, the report warns that such efforts will not, by themselves, be sufficient to solve the world's major problems. "Many tasks are too urgent to wait for R&D to provide solutions and many cannot be solved by science and technology alone. Indeed when new knowledge is used to bolster and extend the power of governments, corporations and ruling elites, it can aggravate the social injustices that lie at the root of many of the world's most urgent problems," says the report. □

Knowledge and Power: The Global Research and Development Budget, by Colin Norman. Worldwatch Paper 31. Available from the Worldwatch Institute, 1776 Massachusetts Avenue NW, Washington DC 20036.

New US group calls for gene resource conservation programme

A DIVERSE group of scientists, concerned over the lack of support for efforts to protect genetic resources met recently in Berkeley, California, to form the National Gene Resource Program Co-ordinating Committee. The committee will initiate a train of events which, it hopes, will culminate in a national conference on gene resource conservation in 1981.

The committee's first action was to circulate a letter requesting other scientists and people concerned with bioresources to bring the problem to the attention of the federal government.

In an interview with *Nature*, the co-ordinator of the committee, geneticist David Kafton, elaborated on the goals of the group. "What we envision is making gene resources a high-priority national issue," he says. The task of the new committee will be to "provide a vehicle for effective action — not just talk."

Critics of the so-called Green Revolution have long pointed out the double-edged danger of over-reliance on just a few strains of essential crops: the chance that disease could wipe out whole harvests very suddenly and that further breeding potential could be lost forever as wild strains disappear. The devastation left by flare-ups of wheat rust, southern corn leaf blight and Dutch elm disease in the United States in recent years has illustrated this point.

Some action has been taken. The National Seed Storage Laboratory in Fort Collins, Colorado, has pioneered practical genetic preservation by storing and protecting seeds of more than 100,000 kinds of food and fibre plants. Bernard Finkle, one of the founding members of the new committee, and his colleagues at the Western Regional Research Laboratory of the US Department of Agriculture in Albany, California, have been experimenting with methods of storing in liquid nitrogen the individual cells of plants usually propagated by cuttings rather than seeds.

Such efforts, however, are too poorly funded to assure the preservation of genetic variability for even essential crops, Kafton says. He cites a memorandum sent last March to Secretary of Agriculture, Robert Bergland, by the National Plant Genetic Resources Board — an advisory body to USDA — outlining the need for greater effort in gene conservation. The National Academy of Sciences has also warned that the "genetic diversity for many species is severely threatened" and has recommended the setting up of a new agency for preserving germ plasms.

Meanwhile, an estimated 200 plant species disappear every year, particularly in areas of developing countries where land is cleared to raise fast-growing new hybrids only. Current levels of sample collection preserve only a small fraction of the existing natural diversity of crops and forests, Kafton and his colleagues insist, and too little research is directed towards finding new methods of conservation.

The letter they are now circulating — really a petition for action — calls for "the establishment of an effective and comprehensive conservation program to ensure the protection of this nation's irreplaceable and invaluable gene resources." Specifically they call for a national conference "whose primary task will be to initiate and design such a comprehensive program."

Technical support for the committee, and other action groups like it, is being supplied by a small, new, non-profit firm called Inquiring Systems Inc., of Berkeley. Loren Cole, an ecosystemologist, is executive director of the company, and David Kafton is one of the staff scientists. Kafton says that the new company is designed to work with groups like the new gene resource committee to stimulate action on social issues through such activities as organizing meetings, training personnel and publishing information.

UN studies new science and technology fund

Keen to avoid an impasse at the United Nations Conference on Science and Technology for Development when it meets in Vienna next month, UN officials are studying the idea of setting up a new mechanism to support activities meeting the goals established by the conference in a way that is acceptable to both developed and developing nations.

The Group of 77 which is currently negotiating such issues on behalf of over 120 developing countries, has already proposed that an international 'financing system' for science and technology for development be established by the UN, largely financed by the developed nations and aimed to grow to $2,000 million by 1985, and $4,000 million by 1990.

Many developed countries, however, have pointed out the political difficulties that they would face in committing themselves to such a fund, both in terms of the size of the contributions involved, and the form in which it is proposed that they be made — namely as 'automatic' contributions assessed, for example, as a percentage of the balance of trade in manufactured goods with the developing countries.

What is now being sought is a formula that might eventually lead to a transfer of funds for scientific and technological activities of the same order of magnitude as the Group of 77 have proposed, but in a form which would be politically acceptable to the countries expected to be the major donors.

A possible way in which this could be done, according to one line of argument now being actively pursued in the UN and elsewhere, is through an initially relatively modest financial allocation — perhaps in the order of $250 million to $300 million — which could both provide some immediate additional support for science and technology activities and establish the basis for exploring the desirability and feasibility of scaling up to the higher budget levels.

The need to increase the finance for science and technology in development has been emphasized in a paper presented to the UNCSTD secretariat by the United Nations Development Programme. One of the suggestions made in this paper is that the conference should examine and, if appropriate, establish "international arrangements to generate and channel additional funds to developing countries . . . . to stimulate research and development activities in priority areas."

The UNDP suggests, for example, setting up an international financing facility which, at the request of a particular country, would support selected research projects in key areas, as well as the development, field testing, pilot production and dissemination "which are so essential in the conversion of research into widespread practice"

Such a facility, it says, would aim to ensure that adequate resources were channelled into key areas, and would arrange to recover its costs in whole or in part in sectors such as industry, where appropriate. It would also attract funds from non official sources, combining an intergovernmental mechanism with a mixture of public and private funds through co-financing.

"If the facility were both effectively managed and secure, it could attract, through co-financing, substantially greater levels of funding than are likely to become available from official sources alone. It would thus provide an important new source of support for a variety of critical links in the development process in many developing countries", says the UNDP.

Addressing a meeting of the development assistance committee of the Organization for Economic Co-operation and Development in Paris two weeks ago, Mr Bradford Morse, UNDP administrator, stressed the importance to developed and developing nations alike of a successful outcome to the UNCSTD conference, for substantive economic and political reasons.

He stated that the UNDP was prepared to upgrade its own scientific and technological activities in line with the general goals agreed by the conference. And he also suggested a possible scenario for agreement between UNCSTD delegates that would include

- The immediate provision of additional funds to support scientific and technological activities in developing countries;
- A committment by the developing countries to work out their most pressing needs in science and technology;
- A careful review of alternative financing mechanisms for meeting these needs, and how these could be built up; and
- Investigation of ways to ensure the adequate involvement of the scientific community in development efforts.

Speaking at a joint Senate and House hearing in Washington last week, Mrs Lucy Benson, US Undersecretary of State for Science and Technology, said that US negotiators at the UNCSTD preparatory committee meeting in New York last month had considered the Group of 77's proposal of a financing system was "somewhat unrealistic".

"We all feel that we will not be able to come up with what is considered an adequate sum of money" Mrs Benson told the congressional hearing. However, she said that members of the US UNCSTD delegation were waiting to hear more about the plans being discussed in the UN for a funding facility along the lines suggested by UNDP. and in particular were waiting for decisions to come out of the executive branch about the type of commitments that the US would have to make in Vienna.

Ambassador Jean Wilkowskizn, US co-ordinator for UNCSTD, told the meeting that there was a suggestion within the UN that a new science and technology facility, if established, might "very much involve the Arab nations".

Officials in Washington last week confirmed that, in principle, those responsible for allocating aid funds within the US are sympathetic to some new type of facility being established for science and technology, particularly since it might parallel on an international basis the type of bilateral activities proposed for the Institute for Scientific and Technological Co-operation (whose fate, following its rejection by the Senate two weeks ago, still hangs in the balance).

The rationale for the ISTC has already been successfully argued for within the administration. On an international level, many may feel that a logical place for such a facility would be the UNDP. Much will depend, however on what type of financial commitment the administration feels that it is able to make in both the short and the long term.

Meanwhile, some speakers at the congressional hearing used the opportunity to express their frustration at the apparent lack of initiatives which the US seemed to be proposing to take at Vienna. "Our objectives for Vienna are fine, but the effort we proposed is scarcely commensurate, unless things change in the next few weeks", said William Carey, executive officer of the American Association for the Advancement of Science.

Mr Thomas Pickering of the State Department, however, told the hearing that the administration had been studying a wide range of possible initiatives, and was making a final selection of those it considered most feasible. Prime candidates are thought to be plans for resources monitoring satellite systems for developing countries (using technology developed by the National Aeronautics and Space Administration), a proposal to assist in setting up a global information network, and plans to link ISTC — if approved — to similar institutions in other developed countries.

Finally, asked whether the developed and developing nations were on the same wavelength as far as negotiations for UNCSTD were concerned, ambassador Wilkowski gave a frank appraisal of the situation. "It came as a shock to the National Academy of Sciences when it realised that this conference is not about science and technology but is political, because it deals with developing country concerns about inequality and dependence. Those are the catalytic forces which have to rise to this conference. It is the desire to overcome them which led to UNCSTD." **David Dickson**

UK energy minister backs conservation and nuclear power

"We must have a balanced energy policy, drawing on every one of the resources available to us", David Howell, Britain's Secretary of State for Energy, told a gathering to celebrate 25 years of the UK Atomic Energy Authority last week.

Mr Howell (above) backed nuclear power — without it, he said, the UK "would not have a realistic policy for meeting this country's long-term energy requirements". But he also stressed the need to tap coal, and conservation, "where savings of 30% or more are available". Mr Howell announced that he was reviewing the UK conservation programme "to see what reinforcement may be necessary in this key part of our energy strategy" □

China eases ideological grip

"CLIMATE" science in the last sixty years" is the title of an article appearing in a recent issue of *Hong qi* (*Red Flag*) written by Chou Pei-yuan — who is in charge of the Chinese Scientific and Technological Association.

Chou expresses his opinion on the further progress of Chinese science, and refers to the role of marxism. While no substitute for science proper, materialism and the dialectics of nature nevertheless constitute a powerful methodological tool in scientific research. He quotes the 'straton' model of hadrons in particle physics and the chemical synthesis of biologically active insulin as examples of advances made by Chinese scientists under the guidance of marxian ontology.

On the other hand, real scientific discoveries may also be made by experimentalists who are not consciously materialists and dialecticians. In the development of any discipline, the general policy should be "let a hundred schools contend", he says. Academic freedom includes the understanding that no scientific model or theory will be rejected, or supported, purely on the basis of politico-philosophical arguments. Lysenko-type mistakes, such as the uncritical refutation in the late 1950s of western psychology, must be avoided.

Chou also reviews the slow and uncertain development of science in China before 1949, when research was hampered by the lack of experimental facilities, and when significant original work was confirmed to geology, biology, palaeontology, archaeology and mathematics. He describes how Chinese science developed in the quarter century after 1949 with the socialist transformation of scientifgic and educational institutions. However, in the last few years, research of a fundamental nature has been largely neglected, and, he says this needs to be remedied quickly.

Chou's final point about the position of scientists is perhaps the most problematical. He mentions the phenomenon of being "hot at both ends but cold in the middle": that the enthusiasm for scientific modernisation among the top leadership and the rank-and-file scientists does not find its way to the mid-level cadres in some parts of the country. He argues that the majority of intellectuals in China are now part of the working class, and that more say in the administration and funding of science should be given to the scientists themselves. They should have the right working conditions so they can concentrate on research. Other problems which need attending to are the rational allocation of research duties to specialists and the implementation of arrangements to reduce the amount of time they spend on household labour. **T.B. Tang**

●China is to spend £3,500 million on cultural, educational, scientific research and health undertakings this year. Nearly half of it will be devoted to the running of institutes under the Academia Sinica and to maintaining scientific research various other departments, according to the latest state budget announcement. □

UK fellowship scheme approved — in principle

BRITAIN'S Science Research Council has given general approval to the establishment of a programme aimed at easing the critical staff stagnation problem which now affects the country's universities. However, its central council last week decided to call for more specific details before giving the final go-ahead to the scheme which would provide special release fellowships to help senior research workers vacate tenured posts that could then be filled by young scientists.

There are a number of drawbacks associated with the scheme but council members were particularly concerned that the programme, which could cost up to £450,000, could give universities an excuse to cut back on their own financing of science departments and transfer funds to other faculties. To prevent this, more specific regulations are now being prepared and the plan will be discussed by the SRC again in the autumn. □

Yugoslavia: no more oil burning

YUGOSLAVIA'S Federal Chamber last week passed an emergency law, banning for the time being any further investment in new power stations and heating plants based on liquid fuel. This move follows a report from the Federal Executive Council which noted that, as a result of increased OPEC prices, Yugoslavia's oil import bill for 1979 will be 37,650 dinars, some 72% higher than the original estimate. Furthermore, increased domestic consumption is unable to keep up with existing supplies, so that last month, for example, certain Yugoslav airports were closed for several days, due to a total lack of aviation fuel.

The emergency bill, however, did not have an easy passage. Originally scheduled for 27 June, it was held up for three weeks by the delegates from Vojevodina province, who demanded a special procedure and moratorium, claiming that the law would endanger the vital interests of the province, and that the situation did not justify a state of emergency. Vojevodina has small but promising oil resources of its own, and recent prospecting operations by the Naftagas enterprise suggest that in the future, Vojevodina may be able to supply up to 5% of the crude oil required by the Belgrade, Novi Sad and Pancevo refineries.

In spite of these discoveries, Yugoslavia's energy planners are rapidly rethinking their strategies to include new developments of the abundant lignite reserves and a re-emphasis on the country's coal mines, many of which have been closed in recent years. Nuclear power, too, receives a new emphasis, and it is hoped to commission one new nuclear plant a year, from 1990 onwards. However, additional funding for the first such plant, at Krsko, is still on the "pending" list of investment, while the proposed site of the second such station on Vir island has had to be abandoned, following protests by local residents and tourist enterprises. As an extraordinary measure, the station will now be built at Prevlaka, a village on the Sava near Zagreb, although Rade Pavlovic, head of the Croation Electricity Board, stresses that all such stations in the future will have to be built on the coast.

Water quality threatens Polish agriculture

Following an unusually severe winter and dry spring, Poland faces a short-fall in the harvest, a situation in which Party Leader Edward Gierek, meeting agricultural 'activists' earlier this month, could only advise them to "take a close look at every field and harvest as much grain as possible. We must not run round looking for possible places where grain can be bought. Firstly, the money is not there, and secondly, we cannot buy grain anywhere".

Although attributable in the short term to exceptional climatic conditions, this short-fall is a symptom of one of the major problems bedevilling the Polish economy, a chronic lack of water. Not only do many parts of the country have an overall deficit of water, even where there is abundent rainfall, there is unsufficient reservoir capacity to store it. In all, Poland's existing 140 reservoirs can hold only 2,800 million m^3 water, some 5% of the mean annual flow of the rivers (for comparison, Bulgaria stores 15%, Czechoslovakia 12% and the Soviet Union more than 14%).

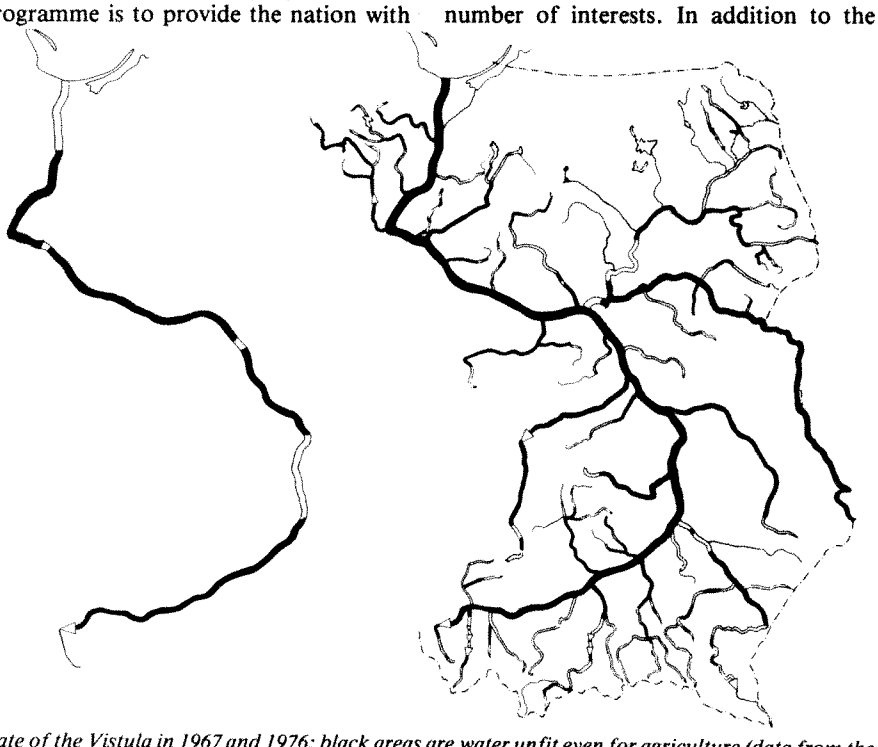
Although the new Vistula Programme, formally inaugurated on 18 June 1978, is designed to remedy this situation to give a storage capacity for the Vistula of approximately 6,000 million m^3, in addition to modernizing the river's transport facilities and building hydroelectric stations. However, provision of water is not sufficient. The Vistula is now so polluted that for much of its length, the water is not even up to the 'second class' of cleanness required for agriculture. A spokesman for the Programme, told *Nature* that "the main purpose of the Programme is to provide the nation with pure water. All the other aspects, transport, hydroelectricity etc, could be replaced by some other means. But without pure water there is nothing we can do."

Like all major technological undertakings in Poland, the Vistula Programme draws heavily on scientific potential throughout the country. Virtually all major Universities and Polytechnics are involved, especially Warsaw, Krakow and Wroclaw. Coordination is the responsibility of the Academy of Sciences.

Although work on the Vistula Programme is not due to start until 1981, the extreme urgency of the situation has led those involved to anticipate the official inauguration. A few administrators have already moved into the half-built office block in the Warsaw suburbs assigned to the Programme, while on the river itself preliminary dredging operations are already in operation. Yet even at this early stage, the engineering operations seem likely to be held up by environmental problems.

Plans for the river include floodwalls which will enclose the present channel and the water-meadows susceptible to flooding; dams will then be built between these floodwalls to create reservoirs with a minimum depth of 2m. The Institute of Ecology of the Academy of Sciences has decided, however, that no dams should be built until the water in that area is up to second class standard, a demand of unparalleled severity.

Cleaning up the Vistula to an extent where largescale engineering operations can commence will involve a considerable number of interests. In addition to the routine problems of industrial outfall and domestic sewage, there is heavy mineral pollution from the mining and industrial belt of Silesia, to say nothing of the Nowa Huta Steelworks near Krakow, where the ecological price of the annual steel output of 7 million tonnes is an emission of 100,000 tonnes of dust and some 70,000 tonnes of SO_2.



Many ecologists concerned with the Vistula Programme see this indirect pollution *via* soil and air as a greater problem than that of wastes discharged into the water, which can, at least in principle, be dealt with by improved sewage, recycling, oil-trap and purification systems. The Academy's Environmental Engineering Institute (situated appropriately, at Zabrze in Silesia), is working on a new electric filter, now at the pilot model stage. Filters and precipitators have in fact installed on all new furnaces at Nowa Huta since the mid-1960s; of them, Professor Roman Andrzeiewski, of the Environmental Engineering Institutes Krakow office simply observed "The filters would be fine if they had an efficiency of 90%". What is really needed, he added is "a technology without dust and without gas!"

Until that utopian situation is achieved, the Institute of Ecology is trying to work out some ecological solution to the pollution problem. In Silesia, valuable data have already been collected on the uptake of minerals. Although it is far too early to propose a general strategy, some partial solutions have been suggested. Zinc pollution, for example, can be remedied by planting birch trees, which can apparently accumulate zinc without harm. Similar methods, say the researchers, can also be applied to agricultural run-offs.

To avoid eutrophication of the future reservoirs, they propose filter zones of live ecosystems on either side of the river. Alder woods are particularly valuable, as too is grass-land, which can profitably be used for grazing. Preliminary studies on the disposal of agricultural chemicals by such filters is going forward in the Mazurian lake disrict. Not only the absorption by flora is being investigated, but also the uptake and "export" of the chemicals *via* the small fauna.

But, faced with a pressing lack of water, as highlighted by the current harvest estimates, will the planners be prepared to wait? It is not, of course, the specific task of the Institute of Ecology to hold them off — but the consensus of opinion seemed optimistic. "We asked the engineers about this last year", said one ecologist, and they said that they would never put a dam where it would make the water quite dead!" "We fell sure that the planners will do what we suggest," said another, "they are actually trying to improve their contacts with us".

State of the Vistula in 1967 and 1976: black areas are water unfit even for agriculture (data from the Instytut Ksztaltowania Srodowiska, Wroclaw)

0028-0836/79/300266-01$01.00

Macmillan Journals Ltd 1979

news in brief

Army worms on the march: Reports from a number of sources indicate that army worms, second only to locusts as a threat to agriculture over much of Africa, are occurring in very large numbers this year in West and East Africa and in the southern Arabian peninsula. Army worms (pictured right), larvae of the Lepidoptera genus *Spodoptera*, attack food, especially cereals, fodder as well as cash crops such as cotton. But in East Africa the most serious damage may be to grazing. In earlier outbreaks, the pest have tended to move northwards in a series of waves and may cause a cattle famine anywhere from Transvaal to southern Ethiopia.

CO1: Crown copyright

The current situation adds urgency to research on the possibility of using the *S exempta* virus as a pesticide. This research was held up last year because no one could locate any army worm outbreaks. Use of *S. Exempta* is the second stage of the virus-and-pheromone concept, the first stage of which, directed against the Mediterranean army worm, (*Nature*, 7 December 1978) has now reached the stage of extended field trials on 5,000 acres in the Egyptian Fayoum — *from Peter Collins in Geneva.*

Soviet call for co-operation on global problems: Academician Dzherman Gvishiani, deputy head of the Soviet Union's State Committee for Science and Technology, has called for a "concerted approach" to the solution in Europe, and ultimately the world, of such major problems as environment, population, water resources, health care, and desertification. Writing in *Pravda*, Gvishiani stressed that such problems can no longer be solved by the efforts of one country alone. In this he differs markedly from Academician Anatolii Aleksandrov, chairman of the Soviet Academy of Sciences, who averred last April that "there is no scientific-technical problem that would not be within our power." Gvishiani, urges the setting up of all-European or inter-state forums to help turn the Helsinki accords into specific action for environmental protection, the development of transport, and energy.

Fire at Windscale causes radiation exposure: Eight workers suffered radiation exposure when a fire broke out on 17 July at a decanning cave at British Nuclear Fuel's Windscale reprocessing plant. The most serious case was 0.3 rem exposure, the equivalent of 10 chest X-rays. This is below the unit of 3 rem in any 13 weeks set for radiation workers by the International Committee for Radiation Protection. The fire occurred when a piece of irradiated fuel rod became jammed in a fuel assembly. Dismounting machinery failed to remove the jammed rod and the fire started, presumably due to friction between the assembly cover and the uranium rods. The fire was extinguished after 45 minutes by flooding the area with water manually through access hole in the top of the cave. Numerous questions remain to be answered about the incident, including the reason for the escape of material and the failure of safety provisions to prevent the event. Community representatives on a BNFL community liaison committee have called for a full investigation "on behalf of the local people and not as a public relations exercise for BNFL".

Czech scientists await trial: Five scientists — mathematician Vaclav Benda, psychologists Jiri Nemec and Dana Nemcova, and (engineers) Ladislav Lis and Petr Uhl — are among ten Czech human rights activists now awaiting trial for "subversion on a large scale". In plain terms, their offence is their membership of VONS, the "Committee for the Defence of the Unjustly Prosecuted", a subgroup of the Charter 77 movement. Since its inauguration, the committee has issued 113 statements on alleged breaches of justice and legality. The ten detainees were arrested on 29 May, and their trial is expected in the next few days. If convicted, they face prison sentences of up to 10 years.

No future for nuclear power plants in Iran: "Only a miracle can rescue both nuclear power stations" an official of the West German engineering company Kraftwerkunion GmbH said last week. He told *Nature* that work permits for the last 50 members of Kraftwerkunion staff will expire by the end of this month. Earlier in the year, there were still hopes that the 6.9bn works would be finished by 1981 the contract was 80% completed. But influential officials are taking a strong line against any nuclear power stations in Iran, and Kraftwerkunion now sees little hope of a resumption of work. The prospect of the plant's cooling towers ending up as grain silos now appears far more likely than before. — *Klaus Höpfner.*

ILL ready for its "deuxième souffle": The renewal programme for one of the world's leading neutron research facilities, the Institut Laue-Langevin in Grenoble, is close to final approval. Funds for ILL's "deuxième souffle" — amounting to 104 million French francs to update instruments and techniques — were approved by the member countries, Britain, France and Germany on 25 May. But because of prior French budget commitments, the detailed spending for the five year programme has been postponed by the French until October. ILL Director John White calls the 25 May approval "extremely good news" and is optimistic that the French difficulty will be resolved.

Jupiter space shot survives budget threat: Project Galileo — NASA's plan to send a joint probe and orbiter mission to Jupiter in 1982 — has survived a threat from a key Congressional subcommittee, some members of which had been threatening to cut off funds to help pay for overspending on the space shuttle. The threat to kill the project came primarily from Senator William Proxmire, chairman of the Senate appropriations Subcommittee responsible for the budgets of both NASA and the National Science Foundation. Senator Proxmire, no great friend of the basic science community, had also suggested that about $20 million be taken out of the budget of the proposed space telescope. However, at a meeting last week the subcommittee refused to go along with either of these proposals, and agreed to recommend to the full appropriations committee that NASA be granted the full $3,822 million in the President's budget request for the fiscal year 1980. Within this total, however, the subcommittee recommended that budget cuts totalling $17 million be allocated to five new projects, including preliminary design studies for a national oceanographic satellite system (a proposed successor to SEASAT), and a multispectral resource satellite.

Islamic technical training centre opens in Bangladesh: An Islamic Centre for Technical and Vocational Training and Research (ICTVTR) began work at Dacca last month, with a board of directors including representatives of Saudi Arabia, Libya, Iran, Iraq, United Arab Emirates, Turkey, Indonesia, Senegal, Gambia, and Bangladesh. The Centre will be built on a 30 acre site provided by the government of Bangladesh at Tongi, 10 miles north of the capital. It will cost $9.6m and is expected to be completed by April 1983. Saudi Arabia has already announced a grant of $2m for the centre. ICTVTR has drawn up a programme for a ten month interim training course in machine shop technology for 50 instructors; and to meet the technical manpower needs of Islamic countries it will undertake training programmes in chemical and mechanical technology, design and drafting, computer programming and technical innovations in oil and gas. — *from M. Kabir in Dacca.*

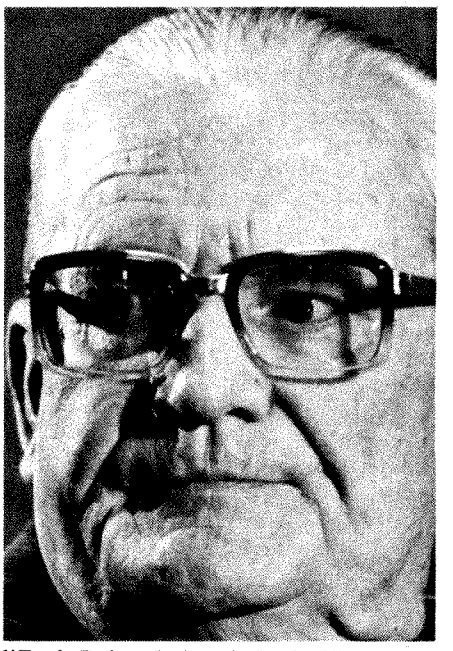
Brazil: is it really safe for the scientists to return?

Brazil's stern leader, President Ernesto Geisel (right), has relaxed some of the restrictions on academic freedom that forced many scientists to leave the country. **Maurice Bazin** reports on the sceptical reaction among the exiles.

THE Brazilian government has recently proclaimed that it will create a gradual democracy and re-establish the right of *habeas corpus*. With this emerges the possibility that some exiled Brazilian scientists may return permanently. Although many exiled scientists have returned on visits in recent months, it is not clear whether the military government really wants them or if they are being tolerated only temporarily. These scientists had been engaged in creating respected research institutions in the early 1960s, but their work was nullified by arbitrary firings and forced retirements imposed by a government afraid of 'intellectual subversion'. As a result, many have been forced into exile, contributing involuntarily to the very 'brain drain' which their earlier efforts in Brazil aimed at eliminating.

A point of convergence for all scientists, both in exile and in Brazil, is the annual meeting of the SBPC, the Brazilian Society for the Progress of Science, now taking place in Fortaleza, a coastal city in the north-east of Brazil. The motto of this year's meeting "Sing there while I sing here" shows how prominent the theme of reunification has become within Brazilian scientific circles.

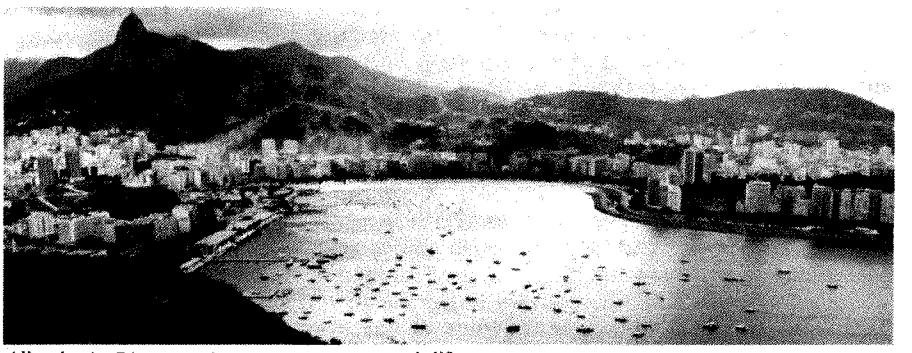


Meetings of the SBPC in past years have been marred by conflicts with the military authorities who wanted to restrict their impact. Two years ago the government forbade all scientists working in federal institutions or using government funds from participating. The meeting's venue should have been the Federal University in Fortaleza, but it was forced to move to a private institution, the Catholic University in São Paulo.

In a well-publicised 'Declaration of Scientists to the Brazilian People', approved by acclamation at the 1977 meeting, the SBPC asked that "scientists fired through dictatorial decrees be reinstated." The declaration also stated that the SBPC "repudiates all censorship of artistic, literary, journalistic and scientific activity. In particular, it repudiates the recent decision of the government to impose censorship upon foreign publications. We see this as a retrograde action, negating the universal character of knowledge and forcing the cultural isolation of Brazilian intellectuals." On its 30th birthday, last year, the SBPC ironically asserted: "the revolution of 1964 was a great stimulus to our economy; the firings and deportations of 1968 and 1969 were also. Each exiled professor costs the country 50 thousand dollars and another 50 thousand to import another who is not *non grata*."

The fact that this year's meeting will finally take place in Fortaleza is a positive step in the process of liberalisation but how many exiled scientists will attend and how many would resettle in Brazil are very much open questions. According to Professor Rocha e Silva, a founder of the SBPC, "some scientists are now living much better in foreign countries. The problem is not of an amnesty, but to convince those who receive the amnesty to come back." For others, however, it is not a question of their standard of living, but doubt about the liberalisation process itself.

"It is ironical that I should return to my country on the occasion of the SBPC meeting; it was during the Society's meeting in 1964 that I was arrested," says Professor Luis Pereira da Silva who now directs the Department of Parasitology of the Institut Pasteur in Paris. "I am going only to renew contacts with the Brazilian scientific community and meet old friends again." In 1964 Pereira da Silva was Assistant Professor in the Medical School of the University of São Paulo; his work on Chagas disease and the chemotaxis of tripanosomes had already received international recognition. He and eight colleagues were fired, with no justification given, under the First Institutional Act, a dictatorial decree of the military regime. At the forthcoming SBPC meeting in Fortaleza he will chair a discussion session entitled 'Who should be responsible for the orientation of scientific research'.



How did Brazil suffer such a massive loss of scientists in the mid-1960s? "We were all free intellectuals, independent thinkers. We wanted to set up modern institutions on a standard academic basis", says Roberto Salmeron, now Directeur de Recherche in high energy physics at the Laboratoire de

l'Ecole Polytechnique in Paris. He was one of the group who conceived the idea of the University of Brasilia, and in 1965 he was coordinator of its Science Division. "We wanted a democratic way of running a university. We used the word 'coordinator' to avoid the authoritarian 'director'. The university was to be a true community and teachers and students were to reside on campus — a very new situation for Latin America."

While Salmeron was trying to build up the science departments, the Rector of the university was changed twice. "The authorities named persons who had the confidence of the military and who were totally subservient. One day the Rector told me that I could not hire a certain professor; he had been called in by unspecified superiors and warned that my candidate was an 'agitator'. Our lectures were taped secretly and we could be asked to explain what we had said in class. Even the names of the composers whose magic was to be played at free public concerts on Saturdays had to be cleared in advance; a conductor was called in for having scheduled a Prokofief work.

"Although the government started dismissing professors during the very first month of the military regime (13 social scientists were dismissed in March 1964) we succeeded in building up a Division of Science with 150 personnel by 1965." The

All calm in Rio — or is it just a temporary lull?

Macmillan Journals Ltd 1979

process of confrontation escalated when a new Rector announced that he would dismiss six other professors. "In spite of our efforts to explain directly to the highest military authorities the value to our country of a modern university, and despite the fact that their sons and daughters were attending it, those in power remained completely insensitive." The result was a series of assemblies of teachers and students, with talks of strikes; finally the army took over and sealed off the campus.

"Nobody could enter the campus, and all our research animals and the flies of the geneticists were going to perish. I alone obtained an authorisation, which read: 'Professor Salmeron is authorised to enter the grounds of the University of Brasilia'. I have kept this piece of official democracy to this day." Finally, towards the end of 1965, as the Rector demanded that Salmeron countersign the firing of not six but 16 scientists, he resigned instead and made public 250 other individual letters of resignation that his colleagues from other departments had prepared. "For five months, we tried to find work as a group of physicists in other Brazilian universities, away from the centre of power that Brasilia represents. We did not succeed and I finally came to Europe, accepting an invitation of Victor Weisskopf, then General Director of CERN."

'I have no confidence in this political overture'

As to whether he will return to Brazil now, Professor Salmeron says "I do not understand what is going on in Brazil. I have no confidence in this political overture — people only do what they are allowed to do. There is some influence coming from the intellectuals, but in the case of the nuclear agreement with West Germany, the influence of the scientists was zero. They were told only after things happened. One should not have illusions. I can only imagine going back in the distant future, and it would depend on the existence of a real stable change in the Brazilian situation which would allow me to undertake projects with a perpsective. I shall not drop everything in Paris to take the risk of losing everything again."

Most other senior scientists who suffered the persecutions and destructions of the past hold the same cautious opinion. Professor Pereira da Silva explains that he "met twice with the fate of losing everything after building a research group; it's already too much." After his first exile in 1964 he agreed to return to a medical school in São Paulo, leaving behind the work on lambda phage on which he was working with Nobel prize winner François Jacob. "This was in 1968 when there appeared to be a political lull. But after nine months spent organising a new laboratory in microbial genetics, I and my colleagues were fired once more, and I went back to the Institut Pasteur."

Another decree of exception, the Fifth Institutional Act, was used in 1969 to fire 25 professors from the University of São Paulo and 44 from the Federal University of Rio de Janeiro. Among the latter was physics professor Jose Leite Lopes, who had also gone back to Brazil in 1968, to the Federal University in Rio. He was also reappointed director of the Theoretical Division of the CBPF, the Brazilian Centre for Physics Research, to which he had previously attracted Richard Feynman and C.N. Yang on sabbatical. Federal funding for physics research had improved substantially in the meantime. But in April 1969, Professor Leite Lopes heard on the radio that he had been dismissed from the University of Rio. "The 44 names were read in alphabetical order; you only waited for yours to come up. That was the end."

A few months later, while lecturing in Pittsburgh, he learned of his further dismissal from the CBPF. "Four colleagues resigned in protest; I got telegrams of support; the SBPC and international societies protested. It was all very comforting at the time. Then there was a lull, to be followed by 12 more firings in 1972 . . . .". He now heads the Theoretical Division of the Nuclear Physics Laboratory in Strasbourg, and says "I shall be going back this summer for the first time in ten years, at the invitation of the physics department of my former university in Rio. Beside this I want to see what it is possible to do, and to discuss ideas. It looks from here as if some progress is being made and I am eager to see how far it goes."

Dr Julio Pudles in Paris takes a still more hesitant attitude. "I was among the nine doctors fired from the Faculty of Medicine in São Paulo in 1964; I was also part of the group which prepared a model for the University of Brasilia in 1963. I was one of those found innocent in our trial in

How the military banned 'exotic ideas'

The life and death of the Oswaldo Cruz Institute in Manguinhos is typical of the long-lasting unstable interaction between scientific institutions and government in Brazil. The Institute was created at the turn of the century, and its first director, Oswaldo Cruz, received his initial training at the Institut Pasteur in Paris. At that time Rio de Janeiro was a swampy, dirty place, harbouring all kinds of epidemics and chronically affected by yellow fever.

In 1902, Oswaldo Cruz publicized Finlay's discovery that the mosquito *Aedes aegypti* was a transmitter of yellow fever, and coordinated a public sanitation plan to eliminate it. Although this plan succeeded in eradicating the disease within a few years, official resistance was great and Cruz was often ridiculed in the press, and even in Congress, for bringing in "exotic theories".

Two years later, Cruz proposed to institute compulsory vaccination against smallpox. A virulent Antivaccination League immediately emerged, bringing together military men, workers' organisations and old-fashioned medical surgeons — whom the young scientists at Manguinhos described as "always wearing dark suits and using their medical authority to declare quarantines and sign autopsy reports in times of epidemics." Their opposition to compulsory vaccination was in the name of individual freedom of conscience: "vaccination was forced upon us and we may even use force against it. This government must be rejected by the people." Partly as a result of the League's campaign, military cadets rebelled in 1904, in an attempt to bring down the first republican government of Brazil. The government, however, won the day and the combined medical and military victories led to dramatic increases in funding for medical research at Manguinhos. In the following years malaria was intensely studied; Carlos Chagas identified the *Trypanosoma crusis* and left his name attached to Chagas disease. Serums and vaccines of all kinds were developed.

"Today," says Professor Ubatuba, "all these achievements seem to be forgotten. That house of science at Manguinhos was destroyed in 1970 when ten of us were forcibly retired. Furthermore, eight of us had our political rights taken away for ten years as stipulated in the Fifth Institutional Act, the act which closed down Congress." The tone had been set by the Health Minister of the military government who had declared, when a new director of the institute took office: "if it is true that there are no frontiers for science, it is also certain that there are frontiers for scientists. The exotic ideas that have infiltrated Manguinhos will be definitely banned . . . Manguinhos of the future will be a busy hive and not what a few wanted, a centre of subversive ideas. The institute will have all the support it needs for its research."

Professor Herman Lent, one of the eight, and former member of the Department of Zoology, recalls in his book *The Massacre of Manguinhos* that the director of the institute had accused its researchers of "conspiring in their laboratories".

A commission of inquiry, headed by a military man, did not find any evidence but it praised the director who "although a poor professional and a poor administrator is a reliable anticommunist". **M.B.**

1966, and I fought unsuccessfully for six months to recover my university post. Dr Pudles would like to go to the SBPC meeting in Fortaleza but hesitates because of the cost. "I paid my own way in 1966, all for nothing."

He sees the SBPC as a remarkable society which has consistently combated arbitrariness and shown tremendous dignity in its support of scientists. But he expresses doubts about returning for good. "My bitterness from the past is very deep. The university may let us return, but with the same positions we had in 1964. We'd find there those same people who wrote anonymous letters denouncing us to the military. When you are over fifty, you cannot run the risk of having to look for a job in France again. France accepted me three times in the past, but the new legislation concerning foreigners working in France is very tough and makes it almost impossible for anyone coming anew to stay permanently."

Passport problems stop some from returning

Some Brazilian research institutions have been modified so much over the past fifteen years that exiled researchers cannot imagine going back. Professor Fernando Braga Ubatuba, a pharmacologist working at the Wellcome Foundation near London finds himself in this situation. "The research institute of Manguinhos in Rio de Janeiro where I worked did fundamental research in medical science with departments of microbiology and parasitology of great renown, but today it has been transformed into a mere generator of vaccines. (see box)

"We all rejoiced on New Year's day this year when President General Geisel revoked the Fifth Institutional Act, and I have recently been back for the Congress of the Latin American Society of Pharmacology. But the case of my colleague Professor Haity Moussatche, now teaching in Venezuela, is more difficult, because our government refuses to renew his passport."

The problem of passports always comes up in the interviews. Those unable to obtain one had to take refugee status in their country of residence abroad. "Now the Brazilian government demands that we first renounce our refugee status before it considers whether it will give us passports," says Alice Rivera of the Centre for the Study of Weak Radioactivity in Orsay near Paris. "I would like to go back but I do not believe I could find work in Brazil now, although my only crime is to be married to an ex-deputy whose mandate was annulled when the military took over in 1964." □

Maurice Bazin is a physicist and science journalist specializing in Latin American affairs.

Can we afford to make the fast reactor safe?

The safety of fast reactors is more difficult to guarantee than that of thermal reactors, so the cost of making them safe is likely to be high. Norman Dombey, of Sussex University, argues that international collaboration is the only way to proceed.

FAST reactors, in particular the liquid metal fast breeder reactor (LMFBR), differ substantially from thermal reactors; indeed as a physicist I take the view, based on the intrinsic physics of the systems, that fast reactors should be considered as a different genus from thermal reactors.

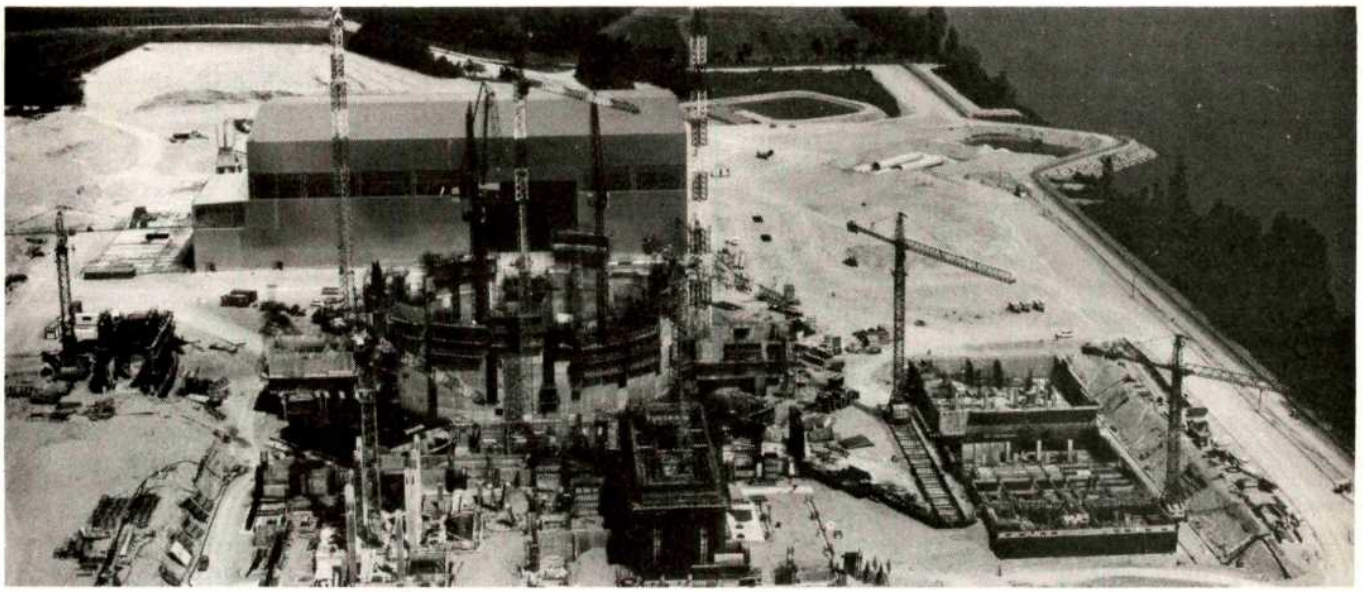
A discussion from this viewpoint illustrates some of the problems of fast reactor development. In this article I should also like to introduce to non-specialists some of the features characteristic of fast reactors, as this information is not readily available outside the technical literature, and finally, I shall draw some conclusions for fast reactor development generally and for the British programme in particular.

The main physical differences between thermal and fast reactors are given in Table 1, the most important point being the last: thermal reactors are designed to be in their most reactive nuclear configuration. This follows from the presence of a moderator without which the natural or slightly enriched uranium fuel of the reactor would not go critical at all. The corollary of this for fast reactors is that as there is more than one critical mass of fissile material in the core of a fast reactor and no moderator, it is not difficult to envisage a rearrangement of fuel to provide a more reactive configuration. As the reaction goes by fast neutrons, it is possible to attain a prompt critical reaction with a large energy release over a very short time. (About 0.2% of the neutrons in a fast reactor are delayed, i.e. come from radioactive daughter nuclei with various half-lives of the order of one second; it is these delayed neutrons which allow a reasonable control of the fast reactor because the prompt neutrons are captured in about one microsecond. A fast reactor is therefore designed to be just critical including the delayed neutrons, but not critical without them; a prompt critical reaction is one which is critical by prompt neutrons alone.) A large energy release over a short time is called a nuclear excursion and cannot occur in normal types of power-generating thermal reactors.

Another important point in this comparison follows from the absence of a moderator in the fast reactor, which allows the fast reactor core to be much smaller than a thermal reactor of the same power. The power density of a fast reactor is about five times that of a light water reactor (LWR). (We should remember that LWRs themselves have a power density about ten times higher than British gas-cooled reactors.) So the coolant used in a fast reactor must have very high thermal conductivity and all the present prototypes use liquid sodium.

It is a job for the licensing authorities in each country to consider hypothetical accidents and to insist on measures to minimise the risk of accidents, and to minimise and contain their effects if they do occur. The discussion of hypothetical accidents begins with an analysis of the reactivity coefficients of the reactor. These coefficients measure the change in reactivity of a reactor as the physical state of the reactor changes. The important coefficients for safety purposes are those related to an increase in power and temperature of the reactor: if the power or temperature increases, a negative coefficient implies that the reactivity will decrease. As commercial thermal reactors operate in the configuration of maximal reactivity, all nuclear reactivity coefficients in these thermal reactors will be negative. For fast reactors, the reactivity coefficient which allows these reactors to be considered as potentially suitable for commercial use is the Doppler coefficient, which measures the change of neutron reaction rates with temperature in the reactor materials themselves. For uranium 238, neutron absorption increases strongly with temperature and hence, there will be fewer neutrons available for fission, so the Doppler coefficient is large and negative.

The fissile material in the core will be plutonium or ^{235}U; for the latter the Doppler coefficient is positive in the same temperature range whereas for plutonium it is small. So in a fast reactor of the design envisaged in CFR 1 or Superphenix with about 20-25% plutonium and 75-80% natural uranium (99.3% ^{238}U) in the fuel rods, there will be no overall negative Doppler coefficient.



It is important to emphasise that the Doppler coefficient, although dependent on core geometry, is primarily an intrinsic nuclear quantity. It depends on the nuclear composition of the fuel used and its

Table 1 Primary differences between thermal and fast reactors

Thermal	Fast
natural or slightly enriched (2-3%) uranium fuel	20-30% enriched uranium or plutonium-uranium fuel
less than 1 critical mass	more than 1 critical mass
moderator	no moderator
thermal neutrons, $\frac{1}{40}$ eV	fast neutrons, keV-MeV
most reactive configuration for nuclear reaction	not most reactive configuration for nuclear reaction

Superphenix, Europe's largest (1200 MWe) fast breeder reactor, under construction at Creys-Malville, France.

arrangement in the core; once an acceptable configuration is found, there is no reason why this configuration should not be scaled up to a larger reactor design.

The second most important reactivity coefficient in fast reactors is the sodium void coefficient. Although fast reactors do not have a moderator, the sodium coolant flows in the core and scatters the neutrons, so to some extent it acts like a moderator in slowing down the neutrons. It also absorbs some neutrons. If the core were to overheat, the sodium could begin to boil; the void coefficient then measures the change in reactivity of the core caused by bubbles of sodium gas forming in the liquid sodium flowing through the core.

Here there are two competing effects. First, sodium gas would absorb and scatter fewer neutrons than liquid sodium, so there would be more neutrons of higher energy and the reactivity would tend to increase. Second, the presence of sodium bubbles would increase the probability of neutrons escaping from the core through the bubbles, so this tends to decrease reactivity.

The first effect leads to a positive void coefficient and is proportional to the volume of sodium in the core, whereas the second effect is an edge effect which is proportional to the effective surface area of the sodium. So for small reactors, where all the sodium can be taken to be near the surface, the edge effect wins and the void coefficient is negative. This was the case for the old 15 MWe Dounreay Fast Reactor. As the reactor gets larger, the volume effect will begin to dominate and the present prototypes such as the Prototype Fast Reactor (PFR) or Phenix have a positive void coefficient, albeit small. The planned CFR 1 or Superphenix, however, will have a large positive void coefficient, about five times larger than that of the present prototypes. So scaling up from a 250 MWe prototype to a 1300 MWe 'commercial' reactor is not simple, because the problems connected with voiding get much worse.

In addition to a comparison of reactivity coefficients, three other factors need to be considered in any comparison of fast reactors with thermal reactors: the fuel-coolant interaction, other non-nuclear problems arising from the use of liquid sodium as coolant, and the general problem of recriticality.

The fuel-coolant interaction is not a nuclear effect: it is the potentially explosive interaction arising when a molten metal comes into contact with a liquid at a temperature much above the boiling point of the liquid. It is well known in the steel industry from incidents where molten steel has come into contact with water, and it is also a problem inherent in water-cooled thermal reactors, as it has been known for a piece of hot fuel rod to melt and interact explosively with the surrounding water. For LWRs, however, the fuel-coolant interaction is less critical than in large LMFBRs because there is an overall negative coolant void coefficient.

The best known difference between thermal reactors and the LMFBR stems from the difficulties of using liquid sodium as coolant in the LMFBR. Sodium is, of course, highly corrosive and interacts vigorously with both air and water on contact. All those large prototypes at present operating (PFR, Phenix and the Soviet BN-350) have been plagued by sodium leaks.

In fast reactors there are also recriticality effects to consider. As the core is not in its most reactive configuration and there may be hundreds of critical masses of plutonium in it, a disruption of the core may lead to a much more reactive configuration; for example, a coolant channel gets blocked, the sodium boils, the reactivity increases because the void coefficient is positive, the cladding of some fuel rods melts and pieces of fuel containing plutonium fall and form a molten mass of plutonium which if large enough can then become prompt critical leading to a rapid release of energy.

The analysis of the energy release and the pressures created by such hypothetical core-disruptive accidents is being pursued in all the countries engaged in fast reactor technology. Enormously complicated computer programs are being prepared to simulate these conditions. Whether or not the present programs are reasonably accurate in describing fast reactor accidents, it is clear that the role of negative reactivity coefficients will be to limit the energy release whereas positive coefficients will enhance it. Thus for a reactor of the size of PFR or Phenix with uranium-plutonium fuel, the energy release for a core-disruptive accident of the type described is not expected to be larger than 400 megajoules (equivalent to about 200 lb of TNT). But in a reactor the size of CFR 1 or Superphenix, the sodium void coefficient is much larger and positive so the energy release for a similar accident could be 2000 megajoules (1000 lb of TNT).

Now the point is not that fast reactors, or large fast reactors, will blow up — it is the job of the licensing authorities after all to ensure the safety of such systems. But the licensing authorities will insist

- on minimising the risk of an accident
- on limiting the damage to the reactor core in the event of an accident
- on maintaining the integrity of the primary reactor system, even in the event of a core-disruptive accident leading to a large energy release
- even in the worst case of an accident breaking the primary system, that radioactive materials are contained.

These are the four lines of assurance of the US authorities, but the practice of the British Nuclear Installations Inspectorate should be similar. The point that I want to make is that measures to deal with the safety and other engineering problems specific to fast reactors will add appreciably to the capital costs of fast reactors compared with thermal reactors of a'

similar size. Yet the goal of a commercial fast reactor system is to produce cheaper electricity than other systems such as thermal reactors. Fuel costs play a minor role in the total cost of nuclear electricity, so that fast reactors will only be competitive with thermal reactors if their capital costs are comparable (unless the price of uranium were to increase dramatically). The special safety requirements of fast reactors and the difficulties of using sodium in LMFBRs both suggest that the capital cost of a LMFBR will be much higher than a comparable thermal reactor. Furthermore, as has been indicated, the safety problems get worse for large fast reactors. It may be thought that my comments are overly pessimistic or overly theoretical — I am after all a theoretical physicist. But the one case study available on the capital costs of fast reactors does indeed bear out my conclusions.

The prototype German fast reactor SNR-300 has increased in cost (at constant 1972 prices) from the initial estimate of DM300 million at the time the reactor was authorised to the most recent estimated cost DM1223 million in October 1975 (O.Keck, University of Sussex Doctoral Thesis, 1977). These are not the final figures and the cost escalation is therefore by at least a factor of four in real terms. Keck also demonstrates that the initial cost estimate of the SNR-300 was in no way based on any evidence about the likely capital costs of fast reactor systems. The estimate was simply a number which the fast reactor proponents thought to be reasonable in view of the likely cost of a thermal reactor system of comparable size — I suspect that the figures we have heard from the AEA about the likely cost of CFR 1 have been arrived at in a similar way. Keck now estimates that the capital cost of the SNR-300 is five times that of a comparable LWR system ordered at the same time.

The importance of this case study is that the SNR 300 is the first and so far the only prototype fast reactor which has been built as if it were a commercial reactor; that is to say it has been built specifically with the goal of satisfying both the utilities and the licensing authorities. Therefore the utilities and the licensing authorities have been consulted from the early design stage in 1969. Keck says "After the designs were submitted drastic alterations became necessary as a result of the safety and environmental provisions demanded by the licensing authorities and substantially increased the costs of the plant... The most severe licensing requirement related to hypothetical accidents. The safety philosophy of the original design placed the emphasis on measures to prevent a core meltdown and a subsequent hypothetical nuclear excursion, and it was thought that this accident could be made sufficiently unlikely to avoid measures accommodating its consequences. The licensing authorities, however, not only required more stringent measures for prevention of this accident, but also stipulated that the impact of a nuclear excursion should be safely accommodated by the reactor vessel and the containment. . . .

"The demands of the licensing authorities not only increased the costs of the prototype plant, but also necessitated a lot of additional research and development in industry and government laboratories, which added considerably to the costs of the fast breeder project. For some items, the licensing requirements even went to the limits of technical feasibility, and imposed heavy tasks on scientists and engineers in industry and government laboratories."

So on the basis of this case study, there is every reason to believe that the licensing requirements for the fast reactor, arising specifically from the physics problems I have outlined, will cause an appreciable increase in capital costs relative to thermal reactor systems. Furthermore, the situation will get worse for larger fast reactors such as CFR 1 and Superphenix.

The relative higher capital costs of fast reactors compared with thermal reactors must be weighed against the prospective future price of uranium. In the words of The Times Mining Correspondent (*The Times*, 30 October 1978) "colossal new discoveries of uranium" have been made in the past three years in Australia and Canada. Therefore "prices are unlikely to go up faster from their current $42 a pound than inflation warrants". So there can be no urgency about developing a commercial fast reactor for economic reasons; it would be more cost effective to spend money on improving the present designs of thermal reactors. Although the AEA talk about a commercial fast reactor, there is no reason at present to use the term commercial. There still remains an enormous amount of basic work to be done on these systems before they can be regarded as a safe, sure and reasonably-priced source of electricity.

My final point is that fast reactors are too hard for us in Britain working alone, since we have neither the resources in money nor in people to do the job by ourselves. The greatest part of the UKAEA's budget and most of its qualified scientists and engineers since the mid-1960s have been committed to the fast reactor but, nevertheless, we cannot match the spending and manpower committed in the United States on fast reactor systems.

The UK is favourably placed for energy until the end of the century, while fast reactors cannot hope to be commercial until next century. A modest programme of research and development is indicated which does not strain the UK's resources, so that it is in a position to benefit from any future exploitation of fast reactors next century. The problem is similar to that in the field of fusion power and the solution is similar: there should be a common European programme of research and development, similar to JET and to the programme of research in elementary particle physics based at CERN in Geneva. If it is too late for the UK to join in the Superphenix project, it should indicate its willingness to join the next reactor after that. With its continuing experience of PFR at Dounreay and its large and assured stock of plutonium it can expect to be welcomed as a partner. I agree with Lord Flowers (*Nature* **264**, 496; 1976) that 'fast reactor developments is likely to be beyond our resources. It seems to me essential that if we propose it at all we should do so on a European basis'.

So it does not make sense for the UK to build CFR 1. On the other hand there is scope for being involved in planning the reactor to be built as a European collaboration (perhaps even the US and Japan would also be interested in participating) after Superphenix. The considerations I have outlined here would suggest that a sensible size for a LMFBR which avoids the problems connected with a large positive sodium void coefficient and which may have commercial potential next century would be about 500 or 600 MWe. PFR, Phenix and SNR-300 provide a sensible basis for the design of a reactor of this size.

France minimises risk of 'worst accident'

WHEN construction was authorised in May 1977 of Superphenix — the fast breeder reactor now being built in south-east France — the licensing authority stipulated that it should be built to meet certain safety specifications. One was that the double-walled reactor vessel, the lid and the dome housing the reactor, should be able to withstand the accidental release of 800 megajoules of mechanical energy. This was the energy which way believed might be released in the 'worse possible accident', that of criticality followed by a sodium explosion.

More recent studies by the French atomic energy authority and others (reported in *Le Monde*, 5 July) however, have concluded that the likelihood of such an accident happening is much lower than had previously been thought: 1 in 10^8 instead of 1 in 10^6. Three independent rod systems, the studies conclude, lower the probability of criticality. Even if the reactor did go critical, then it is highly unlikely that the energy released would be 800 MJ.

The recent studies have also shown, however, that the reactor buildings would be unlikely to withstand 800 megajoule explosions. (It is not ever clear precisely what maximum energy they could withstand.) The question therefore remains whether, given the reduced probability of an 800 megajoule explosion, the licensing authority will still insist that the reactor housing be built to withstand such energies — which would mean a substantial increase in cost. □

The oceanography of fjords

from David M. Farmer and Herbert E. Huppert.

FJORDS, inlets or sea lochs are deep, twisting arms of the world's oceans, generally formed by glacial erosion. In sharp contrast to the depth of the main basin — up to 1700 m — most fjords have a shallow sill at their mouth, of between 1 and 10^2 m, and sometimes with second, third and further sills. All fjords are influenced by the tides, the prevailing winds and fresh water input from rivers. Some, particularly those in the Artic, are covered with ice for part of the year. Many people live along their shores, especially in Scandinavia, and have come to rely on the fjords for water, food, the disposal of waste and recreation. All these demands are interconnected, so that the ill-considered construction of a hydroelectric scheme, for example, will modify the water circulation, which in turn can decrease the production of herring in the fjord and of codling on the continental shelf. Man's intervention can also seriously disturb the millions of juvenile salmon which use fjords as highways on their seaward migration and depend throughout their journey on food produced in the fjords.

Scientifically, fjords provide a relatively simple system for investigations which can also contribute to knowledge of the open ocean. All these aspects were borne in mind at a recent NATO Advanced Research Institute on the physical, biological and chemical oceanography of fjords.*

G.L. Pickard (University of British Columbia) and B.R. Stanton (New Zealand Oceanographic Institute) have compiled a detailed description of the water characteristics in Pacific fjords. In contrast to the open ocean, their density structure is controlled almost entirely by salinity (rather than temperature). In Pacific fjords the salinity almost always increases with depth, whereas the temperature and dissolved oxygen generally decrease slightly. The river run-off near the head of each fjord, although very variable, can make an important contribution to the circulation. Fjords with high river run-off have well-mixed layers up to 10 m in depth, and there tends to be some movement in the deep water. The Alaskan and Chilean fjords with glaciers flowing into them, in contrast to those without, tend to have a positive dissolved oxygen anomaly at depth and a stepped salinity structure. This can be explained in terms of the predominantly horizontal flow, in a series of layers, of the glacier melt water and the extra oxygen contained in the ice as suggested recently (Huppert & Turner *Nature*, **271**, 46; 1978). Although morphologically similar to Pacific fjords, Scandinavian fjords typically experience smaller tides and this may have important consequences for the types of mixing process which dominate. A further distinction is that New Zealand fjords are short, have relatively deep sills and their circulation, in contrast to other fjords, tends to be set by the oceanographic conditions along the coast.

R.R. Long (Johns Hopkins University, Baltimore) felt that rare but severe disturbances, such as bad storms, could be responsible for a considerable amount of the vertical mixing and affect the circulation in fjords and in the deep ocean. The concept that rare, large, inputs might be considerably more influential than the inputs usually observed, was much discussed, but the final consensus was that the available data from all sources were not sufficient to make a definitive statement.

The renewal of deep water, due to the occasional flow of relatively heavy water over the sill into a fjord may occur over a range of time-scales — as infrequently as only once every 7 years in one case — in response to a combination of tidal range, strength of the off-shore winds, amount of river run-off and interaction of the flow produced by these effects with the major sills (A. Edwards, Dunstaffnage Marine Research Laboratory, Scotland). In between renewal, diffusion and mixing slowly decrease the salinity at depth, thus helping to promote the next renewal. Mixing may be the result of the breaking of internal waves and of turbulence generated by the tidal flow past the boundaries, although the magnitude of both these mechanisms is uncertain. D. Dyrssen (Göteborg University, Sweden) drew attention to the practical importance of deep-water mixing in connection with pollution. Deep water exchange is also crucial in determining the amount of available oxygen, which in turn produces changes in the distribution of species and alterations in feeding behaviour.

From the results of the JASIN (Joint Air-Sea Interaction) experiment R. Pollard (Institute of Oceanographic Sciences, UK) pointed to three mixing processes believed to be relevant to the oceanic thermocline and possibly to the halocline in a fjord. First, there is the instability, wave breaking and mixing due to shear, which Pollard believed to be infrequent and unimportant in the oceanic thermocline. Second, there is the motion along isopycnals, as for example, across fronts. Third, there is the motion across isopycnals due to double-diffusive effects. The importance of the last effect is still controversial, but data from the open ocean continue to affirm its influence and Pollard discussed additional confirmation in data taken by M. Gregg (University of Washington, Seattle). Laboratory experiments by B.R. Ruddick and J.S. Turner (*Deep-Sea Res.*, in press) indicate that double-diffusive effects may also play a part in mixing across fronts. Pollard then pointed to processes believed to be relevant in the mixed layer: the generation of Kelvin-Helmholtz billows, with subsequent mixing, surface wave breaking and Langmuir circulation due to interactions between surface waves and shear in the water. Various theoretical models have been proposed to predict features of the upper mixed layer, but it seems that the models are more sophisticated, though less realistic, than warranted by the data.

One of the most comprehensively observed North American fjords is Knight Inlet in British Columbia and an impressive array of phenomena have been documented there. Acoustic soundings indicate that there is a large amplitude internal response to the tidally forced flow

* The Fjord Oceanographic Workshop was held at the Institute of Ocean Sciences Patricia Bay, British Columbia from 4 - 8 June, 1979. The proceedings are to be published by Plenum in their Marine Science Series, edited by D.M. Farmer and H.J. Freeland.

over the sill. At the beginning of the ebb tide, the flow separates behind the inner sill and there is a large amplitude periodic disturbance on the shear layer emanating at the sill crest, at a depth of approximately 60 m. As the tidal flow increases, a large-amplitude, stationary lee-wave train, or more usually an internal hydraulic jump, is set up in the stratified layer in the lee of the sill. Such an event is shown in the illustration along with the laboratory simulation. The strong flow associated with the accelerated flow down the lee face of the sill suppresses the separation, in agreement with recent theoretical and laboratory experiments of P. W. M. Brighton (Ph.D. Thesis, University of Cambridge). As the tide slackens, waves propagate upstream, since their phase velocity is now larger than that of the opposing tidal flow. This is the same phenomenon as documented by acoustic measurements in the vicinity of Stellwagen Bank in Massachusets Bay (Haury, Brisco & Orr *Nature* **278**, 312; 1979), a model of which was investigated in the laboratory (Maxworthy *J. geophys. Res.* **84**, 338; 1979). From measurements taken by the small manned submersible Pisces IV, A. Gargett (IOS, British Columbia) found that the wave train in Knight Inlet has an amplitude of 10 m, is highly turbulent and has a very strong down-ward velocity at its front. The flood tide may set up a similar train of waves, which propagate downstream as the tide slackens, but they are of smaller amplitude and possibly of different character because of the asymmetric geometry of the sill.

Long discussed refinements of his two-layer frictional model for the circulation in a fjord, presenting an updated parameterisation of the friction to allow for a better comparison with data from Knight Inlet. Nevertheless, a consequence of the model, that the Froude number at the mouth be 1.0 (the critical value) is not reflected in recent data taken in Knight Inlet, which indicates that the value is close to 0.3.

Some of the many practical problems in fjords were skillfully described by Scandinavian workers. Careful consideration of the energy exchange between the barotropic and baroclinic tidal response over a sill indicates that some fjords have constrictions which make them close to resonant. This suggests that relatively small modifications of the constriction, such as altering the depth of the sill or placing a floating bridge or barrier over the sill, may bring the fjord closer to resonance. This would increase the tidally-generated internal response and lead to enhanced mixing.

The siting of hydropower installations and the depth of the fresh water discharge into a fjord can have enormous influence on the water characteristics; in particular, a fresh water layer, sufficiently deep and cold, on the top of a fjord can promote undesirable ice cover throughout the winter. T. Carstens (Norwegian Institute of Technology, Trondheim) explained that submerging the output and introducing compressed air into it enhances the mixing in the upper layers and increases the salinity at the surface, thereby inhibiting ice formation. T.A. McClimans (Norwegian Institute of Technology, Trondheim), described models for the point release of a fresh water supply into a fjord, incorporating tidal effects, which have been successfully used in a number of situations.

A novel technique for studying the circulation in the Clyde Sea Area fjord involving the use of radioactive pollutants from Windscale was presented by I.G. McKinley (University of Glasgow, Scotland). Caesium-134 and 137, which have different half lives (2 and 30 years), provide an ideal tracer pair for studying vertical diffusion, sedimentation rates and other exchange processes. The caesium was detectable as far away as off Northeast Scotland, suggesting that this procedure may be ideally suited for ocean circulation studies elsewhere. □

Changing cometary orbits

from David W. Hughes

Two principal mechanisms are available for changing the orbit of a comet. The first is gravitational and relies on the proximity of a planet to perturb the comet's path. The change in the reciprocal of the semi-major axis of the orbit then suffers a random walk which is approximately proportional to the square root of the number of returns the comet makes to the inner Solar System. The second is non-gravitational and is due to the fact that gases given off by the cometary nucleus are not emitted symetrically in all directions. The importance of this second force was first realised in the early 1820s when Comet Encke consistently passed perihelion 2.5 h before the predicted time.

Imagine an icy conglomerate cometary nucleus which is not rotating. The maximum emission of the sublimating volatiles will occur on the sunward side, around the subsolar point. This jet of gas will effectively exert a force on the nucleus in the direction away from the Sun. Now if the nucleus rotates and if there is a time lag between the absorption of the solar radiation by the dusty surface of the nucleus and the sublimation of the cometary ices, then the effective force is not radial; this force will have a transverse component along the orbit of the comet and also a normal component perpendicular to this orbit. Marsden, Sekanina and Yeomans (*Astron. J.* **78**,

0028-0836/79/300274-02$01.00
©Macmillan Journals Ltd 1979

211; 1973) found that the radial force was typically 10 times the transverse force and that the normal component was either zero or undetectable. This implies that the lag angle (the angle between the solar direction and the line from the centre of the nucleus to the maximum emission point) is on average about 6°. Such a low value indicates that the nucleus is either spinning slowly, with a period of 24 h or more, or that the spin axis is nearly perpendicular to the orbital plane, or that both these conditions are operative.

Interestingly there seem to be as many comets with positive transverse forces as with negative ones. So direct rotations (like the Earth's) and retrograde rotations are equally probable.

The effects of these transverse forces are also rather interesting and they have been investigated by Paul R. Weissman (Jet Propulsion Laboratory, California) in a recent edition of *The Astronomical Journal* (**84**, 580; 1979). If the cometary nucleus has a direct rotation, the transverse force increases the energy and the angular momentum of the orbit and both the perihelion distance and the aphelion distance get larger. The comet moves away from the Sun. The opposite occurs for retrograde rotation. Now planetary perturbations produce a random walk variation in orbital parameters whereas non-gravitational forces are much more effective. Assuming that the spin axis direction does not vary, the value of the reciprocal of the semi-major axis undergoes regular, unidirectional steps and the total change produced in this quantity is simply a function of the number of times the comet passes close to the Sun.

Non-gravitational forces are responsible for changing the orbits of many of the short-period comets. Weissman suggests for example that they have decreased the semi-major axis of the periodic comet Encke and have pulled it away from the influence of Jupiter. This effect can thus greatly increase the inner Solar System lifetime of these short-period comets and there is the possibility that they could lose all their ices without violent disruption and so evolve into Apollo or Amor-type asteroids. The action of non-gravitational forces on long-period comets is much more difficult to assess simply because these are only seen at one apparition.

Weissman also considers the Kreutz family of Sun-grazing comets. The change in the reciprocal of the semi-major axis, a, that these non-gravitational forces can produce, increases strongly as the perihelion distance gets smaller. The Kreutz family have perihelia in the region between 0.005 and 0.009 AU, well within the solar Roche limit. Typical values of $\Delta(1/a)$ lie in the range 10^{-3} to 10^{-1} AU^{-1} and can easily change the aphelion distance from around 4×10^4 AU (well within the Oort cloud) to their present value of about 100 AU, in two or three returns.

Of course there are still many problems requiring solutions. Do the spin periods and spin axis directions of cometary nuclei vary with time? What made them spin in the first place? Are the spin axes directions randomly orientated in space and if so why? F.L. Whipple (*IAU Colloquium* **39**, 25; 1977) reminds us that the cometary nuclei are irregularly shaped objects that can lose up to 1% of their mass at each perihelion passage. Also the mass loss is irregular and often occurs disruptively. These factors can all lead to a change in the spin axis direction and the spin rate.

Another mechanism that can change the spin rate has been discussed recently by R.L. Hawkes and J. Jones in *The Monthly Notices of the Royal Astronomical Society* (**185**, 727; 1978). They consider the effect of micrometeoroid ablation on the spin rate of the meteoroids responsible for the radio and visual meteors seen in the Earth's atmosphere. Particle impacts on an irregular body will produce a change in the angular momentum and the total angular momentum will increase in a random walk fashion. Even though on average there will be as many collisions causing increases in the spin rate as there are causing decreases, there will be an incomplete cancellation due to the statistical fluctuations of the opposing torques. According to Hawkes and Jones the meteoroids spin up until rotational energy becomes comparable to the translation energy. The meteoroids would then be spinning at about 1000 revolutions per second indicating that comets with their spin periods of many hours have a long way to go. □

Progress in thalassemia research

from David G. Nathan

INVESTIGATIONS of normal haemoglobin have paved the way for understanding the anatomy and physiology of the human genome and research into Cooley's anaemia has been well in the vanguard. At the fourth symposium on Cooley's anaemia,* an international group of clinicians and basic scientists met to review the remarkable progress made in understanding, treatment and prevention of this inherited disease.

Cooley's anaemia, or the β-thalassemia syndrome, together with the various α-thalassemia syndromes are the result of unbalanced synthesis of globin chains secondary to decreased production of functioning mRNA. This mRNA deficit is sometimes due to specific gene deletions. More commonly, the structural gene is present but ineffectively contributes to globin synthesis. Application of restriction endonuclease gene mapping techniques to normal DNA and to DNA bearing globin gene deletions by R. Bernard, R. Flavell and R. Williamson (University of Amsterdam and St. Mary's Hospital Medical School London) and J. Mears and A. Bank (Columbia Univesity, New York), has provided a physical map of the $G\gamma$ - $A\gamma$ - δ - β globin regions in chromosome 11, one that spans more than 40 kb (kilobases). The intergenic distances are now established. Maps of several different deletions in this region, all of which cause complete absence of β globin synthesis (β^0 thalassemia) have been provided by B. Forget (Yale University), T. Maniatis (California Institute of Technology; also *Nature*, **279**, 598; 1979), Mears and S. Orkin (Children's Hospital Medical Center, Boston). They range from a 0.6 kb deletion at the 3′ end of the β gene to much larger deletions that cause either $\delta\beta$ thalassemia or hereditary persistence of fetal haemoglobin. In the latter diseases the known deletions include one of at least 30 kb encompassing all of the DNA from the area immediately 3′ to the G γ gene through to the 3′ end of the β gene and another of at least 13 kb encompassing the 3′ half of the δ gene through to the 3′ end of the β gene. Whether a firm relationship exists between the extent of gene deletion 5′ to the β, and γ chain synthesis is uncertain from the few cases studied to date.

Two laboratories have reported successful cloning of the β^+ thalassemia genes. So far molecular lesions clearly responsible for disturbances in transcription or mRNA processing have not emerged. Forget reports no abnormality in the 5′ end of the larger β intron (intervening sequence). Unambiguous interpretations of these clones may be difficult because the data already suggest substantial normal molecular heterogeneity in and around the 5′ regions of the β gene. The search for a molecular basis of non-deletion forms of thalassemia will require painstaking sequencing of long stretches of DNA and use of functional systems for detecting gene expression.

Chang and Y.W. Kan (University of California, San Francisco) have clearly ascribed one form of β^0 thalassemia to a nonsense mutation at nucleotide codon 17. The nonsense-containing mRNA can be translated in a cell-free system if a suppressor $tRNA^{Ser}$ is added. This is the first description of a nonsense mutation in man.

The α-thalassemias have been investigated by S.E. Embury (University of California, San Francisco) and Orkin. 'Non-deletion' forms of α-thalassemia genes are commoner than formerly appreciated and single deletions of one of

*The Fourth Symposium on Cooley's anaemia, co-sponsored by the New York Academy of Sciences and the Cooley's Anaemia Foundation Incorporated, was held in New York on 21-23 May.

©Macmillan Journals Ltd 1979

the pair of duplicated alpha genes is very common in blacks accounting for the rarity of α-thalassemia-induced hydrops fetalis in that race.

Kan, B. Alter (Children's Hospital Medical Center, Boston), A. Cao (University di Cagliari, Sardinia) and D. Loukopoulos (University of Athens) all reported that prenatal diagnosis of β-thalassemia by fetal blood sampling is now an established procedure. Endonuclease mapping of fetal fibroblast DNA can also be used in the deletion forms of β-thalassemia, in certain West Africans with sickle cell anaemia and α-thalassemia.

R. Propper (Boston), A. Nienhuis (National Institutes of Health, Bethesda) and S. Piomelli (New York University Medical Center) reviewed therapeutic advances in which new approaches to transfusion with young red cells and continuous subcutaneous infusion of deferoxamine can achieve negative iron balance in these repeatedly transfused patients. New approaches to computerised radionuclide cardiac scanning will probably permit better evaluation of the effects of this treatment on cardiac function.

Whether the long-sought goal of increased fetal haemoglobin synthesis can be achieved in patients with β-gene defects was debated somewhat inconclusively by G. Stamatoyannopoulos (University of Washington, Seattle), Nienhuis and Nathan. Normal erythroid stem cells do form differentiated colonies that vary in their capacity to express γ genes. One human erythropoietic cell line (K562) derived from a patient with chronic myelogenous leukaemia was reported by T. Rutherford and D. Weatherall (The Radcliffe Infirmary, Oxford). When stimulated with haemin, this cell line exhibits α, ζ, ε, and γ gene expression (*Nature* **280**, 164; 1979). W. French Anderson (National Institutes of Health) reported progress in cell fusion studies inthat hybrids formed by human fibroblasts and 2-S mouse erythroleukaemia cells produced human β, but not γ mRNA. A specific positive regulator is apparently present in these interesting hybrids.

It seemed clear to all participants that advances in haematopoietic stem cell culture and in globin gene cloning may lead to marrow autotransplantation experiments in animal models in which new functioning globin genes may be incorporated into replicating stem cells and globin chimaeras created in the laboratory. Whether these techniques will be applied in man will await much more refined methodology. In the meanwhile, prevention by prenatal diagnosis and improved therapy are available. Progress at the bench and bedside is indeed exciting in this fascinating field. □

Quark fusion

from Peter Landshoff

EXPERIMENTS in which beams of high-energy electrons, muons or neutrinos are scattered on a hydrogen target give good, though indirect, evidence that the proton is made of quarks. The evidence is indirect because no free quarks have yet been seen, and indeed most high-energy physicists have come to believe that quarks can only occur in bound states such as protons or π-mesons. For this reason, it is valuable to have other types of experiment that confirm the quark structure and give more information about it. In the experiments that are most straightforward to interpret, a lepton pair is produced in the collision of a proton or pion beam with a hydrogen target, or with some heavier nucleus. The lepton pair may be either an electron and a positron, e^+e^-, or a muon pair $\mu^+\mu^-$.

It was experiments of this type that made the important discoveries of the J/ψ and Υ resonances. The Υ are responsible for the structure near 10 GeV in the data shown in Fig. 1 from the Columbia-Fermilab - Stony Brook collaboration, where the production cross-section is plotted against the invariant mass, m, of the lepton pair. Attention is now turning to a more accurate exploration of the continuum, that is, to values of m not near a resonance. In 1970, S.D. Drell and T.-M. Yan predicted that, in experiments with high-energy beams, dilepton production in the high-mass continuum would take place through quark fusion. The Drell–Yan mechanism is best visualised in the centre-of-mass frame, in which the beam particle and the target both move towards each other with large momentum and collide. At that time, it was already known, from experiments in which high-energy electrons scattered on protons, that a substantial part of the momentum of a fast-moving

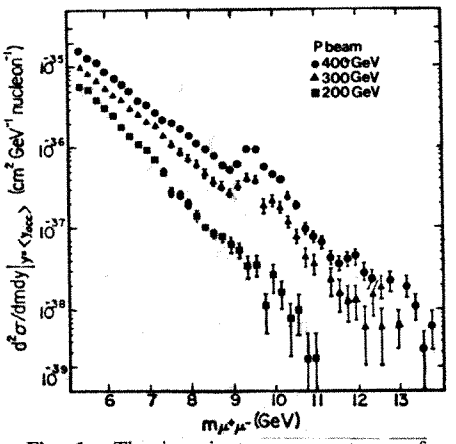

Fig. 1. The invariant-mass spectrum of $\mu^+\mu^-$ pairs produced by high-energy proton beams colliding with a heavy target. The structure around 10 GeV is associated with the Υ resonances (Columbia-Fermilab-Stony Brook). From a talk given by John Dowell at an Institute of Physics meeting in April, 1979).

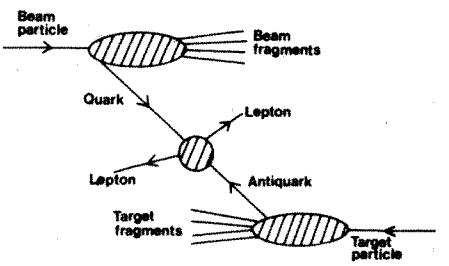

Fig. 2. The Drell–Yan mechanism, in which a quark and an anti-quark fuse to form a lepton pair.

proton is carried by three quarks, known as its valence quarks, but that in addition the proton contains a large number of slow-moving pairs of quarks and antiquarks. In the Drell–Yan mechanism, a quark from one of the two initial colliding particles fuses with an antiquark from the other, and the energy of the quark-antiquark pair then materialises again at the lepton pair (Fig. 2).

The experimental results agree well with this picture. In particular, the proton-beam data verify that the production cross-section $d\sigma/dm$ obeys a scaling law. This is predicted from the fact that quarks and antiquarks have very small radius, or maybe are even pointlike. This implies that the production must be essentially independent of any fixed parameter that carries dimensions, and, since $d\sigma/dm$ has dimension (mass)^3 in units where $\hbar = c = 1$,

$$\frac{d\sigma}{dm} = \frac{1}{m^3} F(\tau).$$

Here F is a dimensionless function of the only dimensionless variable associated with the production, $\tau = m^2/s$, where $\sqrt{s}$ is the total energy measured in the centre-of-mass frame. The test of scaling is shown in Fig. 3, where it is seen that $m^3 d\sigma/dm$ plotted against τ is independent of beam energy, or equivalently of the centre-of-mass energy $\sqrt{s}$. Data at rather higher centre-of-mass energies are now beginning to come from the CERN Intersecting Storage Rings, and they also seem to be in agreement with scaling. In the case of π-meson beams, scaling sets in only at rather larger values of m; why this should be is not understood.

The proton-beam data agree well with quantitative calculations of $F(\tau)$. These calculations use as input the momentum distributions of the quarks and antiquarks within the proton, as measured in the electron, muon and neutrino scattering experiments. However, these experiments determine well the momentum distributions of the valence quarks, but much less well those of the antiquarks, and the dilepton production experiments actually give the best determination of the antiquark distributions. Because of its very short lifetime, the π-meson cannot be used as a target, and so there is no information

Peter Landshoff is Reader in Mathematical Physics at Christ's College, Cambridge.

0028-0836/79/300276-02$01.00

©Macmillan Journals Ltd 1979

about its structure from electron, muon or neutrino scattering. But muon-pair production from pion beams, when interpreted in the Drell-Yan picture, agrees well with theoretical prejudices about the momentum distributions of quarks within the pion. Quarks are known to have spin ½ and at values of the invariant mass m high enough for scaling to have set in, the angular distribution of the produced muons is found by the Chicago-Illinois-Fermilab collaboration to correspond with that predicted from the fusion of a pair of particles of spin ½.

One surprising property of the Drell-Yan continuum was discovered by the Columbia-Fermilab-Stony Brook collaboration. It was expected that the dilepton system would emerge from the reaction with its total momentum in a direction closely parallel to the incident beam momentum, but it is found that rather often this is not so. Theorists would like to interpret this as a natural consequence of quantum chromodynamics. This is believed to be the quantum field theory associated with the strong interactions that hold quarks and antiquarks together within protons and pions. Just as in quantum electrodynamics the electromagnetic force is transmitted by a particle, the photon, so in quantum chromodynamics the strong force is

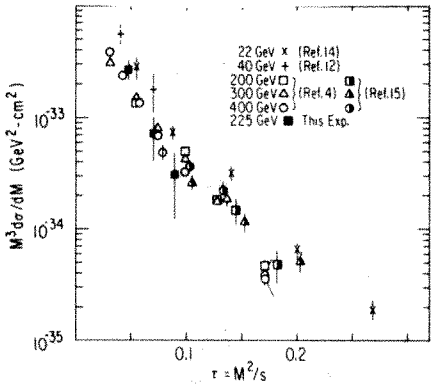

Fig. 3. Test of scaling: plots of $m^3 d\sigma/dm$ for various energies of the incident proton beam (Chicago-Illinois-Princeton). From Anderson *et al. Phys. Rev. Lett.* **42**, 944; 1979).

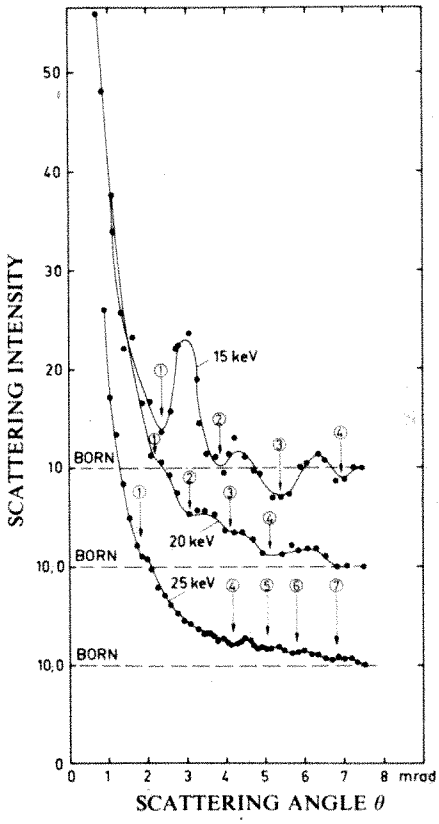
thought to be transmitted by a particle called the gluon. The bremsstrahlung of gluons by the quarks and antiquarks before they fuse can appreciably change their directions of motion, and so may account for the large transverse momentum component of the dileptons. If this is the correct explantion, the gluon bremsstrahlung will have other consequences that can be checked in accurate experiments, including small but well-defined deviations from scaling and from the simple expectations for the angular distributions. The strong interest of both experimentalists and theorists in the Drell–Yan mechanism seems likely to continue. □

A new form of electron diffraction by atoms

from C. B. Lucas

STUDIES of electron scattering by free atoms have now over 50 years of history, so it is surprising that a new diffraction phenomen has just been discovered by Geiger and Morón-León (*Phys. Rev. Lett.* **42**, 1336; 1979).



The first experiments which showed that electrons have a wave nature and so undergo diffraction effects were those of Davisson and Germer in 1927, using a crystalline taget. These experiments overshadowed the studies of electron scattering from free atoms which started at about the same time. As Bullard and Massey stated in 1931: "It will be seen that the . . . curves exhibit general similarity to those representing the intensity of light scattering from small spheres . . . However the analogy must not be pushed too far as the electron wavelength varies very rapidly in the region of the atom."

In so well-established a field, little general interest is aroused by the majority of current publications on elastic electron scattering. Recent progress has mainly been directed towards increased accuracy of experimental data and increasingly sophisticated numerical calculations. Though great interest was aroused by the discovery of resonance phenomena, which caused narrow structure to be seen in the scattered intensities, certainly the most outstanding discovery of recent times was also made in the 1960s — that electrons scattered from heavy atoms are spin-polarised. This confirmed predictions made by Mott in 1929, using the relativistic form of the Schrödinger equation, which had been introduced by Dirac only a year earlier. Even this exciting discovery did little to raise the prestige of elastic electron scattering studies as very few surprises emerged. Also, the unfortunate fact was soon discovered that large values of polarisation were only obtained in the scattering minima. This is because the polarisation is caused by an angular displacement of the scattered intensity for electrons of different spin directions, but the maxima are broad and thus insensitive to the displacement. In other words, electron scattering has only yielded very small currents of polarised electrons, so interest in ways of producing polarised electrons rapidly switched to other fields.

The electron scattering maxima and minima are found at electron energies ranging from a few electron volts up to many hundred, especially in the heavier atoms. Quite deep minima in the scattering intensities are observed at scattering angles ranging from beyond the forward peak to well into the backward scattering region.

The new electron diffraction was discovered by Geiger and Morón-León at higher electron energies and at scattering angles of less than 0.5°. It occurs not by diffraction on the atom itself but from a kind of shadow around the atom produced by other scattered electrons. This diffraction had not been predicted theoretically, although the reason for its occurrence is easily understood.

In general, the intensity of electrons which are scattered elastically at any scattering angle is larger than the intensity of electrons which have lost some of their energy, for example by exciting or ionising the atom. These inelastically scattered electrons, however, dominate the forward scattering, especially at high energies, where their intensity is typically 1000 times greater than the elastic. So if only the

Shadow diffraction in neon at electron energies of 15, 20 and 25 keV. For clarity the three curves have been displaced and the orders of the diffraction minima have been numbered.

THE statement on page 4 of the *News and Views* article prepared by Leffert and Koch, entitled 'Ionic Landmarks Along the Mitogenic Route' (*Nature*, **279**, 104; 1979) is incorrect. Proteolysis does not convert myelin basic protein into a mitogenic peptide whose sequence is Thr-Pro-Pro-Pro-Ser-Gln-Gly-Lys. What I stated at the conference was that from our data the brain FGF activity resides within region 91-117 of the basic protein. However because of the effects of other portions of the molecule on mitogenicity one would not expect that this region itself would be mitogenic.

FRED C. WESTALL

©Macmillan Journals Ltd 1979

elastically scattered electrons are detected, it appears as if the atoms were surrounded by large opaque fuzzy-edged disks, or shadows, since almost no elastically scattered electrons can appear at small scattering angles. It is these disks which are responsible for the diffraction effects.

It is clear by comparison with light diffraction that diffraction effects become easier to observe when the diffracting object is not very large compared with the wavelength of the diffracted beam. So it is not surprising that shadow diffraction has remained undetected for so long. The experimental techniques necessary for its observation are more difficult than for large angle scattering, and there was no theoretical prediction.

The apparatus used by Geiger and Morón-León is similar to an electron microscope in which the specimen is replaced by the target gas at a pressure of about 0.1 Torr. A diminished electron optical image, 8 μm in diameter, of the cathode is formed in a filter lens. This is so arranged that all electrons which have lost energy by any inelastic collision with the target atoms see a potential hill which they cannot surmount, and so fall back; that is, they are reflected by the filter lens. The remaining elastically scattered electrons are imaged by the filter lens onto a photographic plate.

Measurements were made in helium, neon and argon. Typical results obtained with neon are shown in the figure, from which it is clear that the diffraction effects are more pronounced at lower energies. The well-known Born approximation, which is flat over this narrow angular range, is used for normalisation purposes. The orders of the diffraction minima are numbered. Geiger and Morón-León assume that the radius R of the disk is equivalent to a 0th order diffraction maximum of angular full width at half height $\theta = \Delta E/E$ where ΔE is the energy lost by the inelastically scattered electrons of primary energy E. This gives an energy dependent radius R of the disk given by $R = 2/k\theta$, where k is the wavenumber of the incident electrons. In the case of the 15 keV electrons scattered from neon, if it is assumed that the main energy loss, ΔE, is due to excitation of the resonance line at 16.9 eV, the radius of the scattering disk is 30 Å, or some 23 times larger than the kinetic theory atomic radius. This agrees exactly with the value of the radius which can be obtained by substituting the measured minima shown in the figure in the Fraunhofer diffraction equation. Good agreement is also obtained in all other cases, where the diffraction angles are not so accurately measureable. So the remarkably simple model of an opaque shadow disk without a fuzzy edge gives an excellent explanation of the observations.

Clearly shadow diffraction now awaits a more detailed theoretical treatment, preferably including electron spin effects. Rapidly changing intensities are an indication that spin polarisation effects are to be expected. For example, in addition to the spin polarisation measurements discussed above, electrons elastically scattered in the neon resonances were shown to be polarised by Franzen and Gupta in 1965. Since spin-up and spin-down electrons could see a different-sized shadow, shadow diffraction may well produce polarised electrons where the intensities are by no means small. □

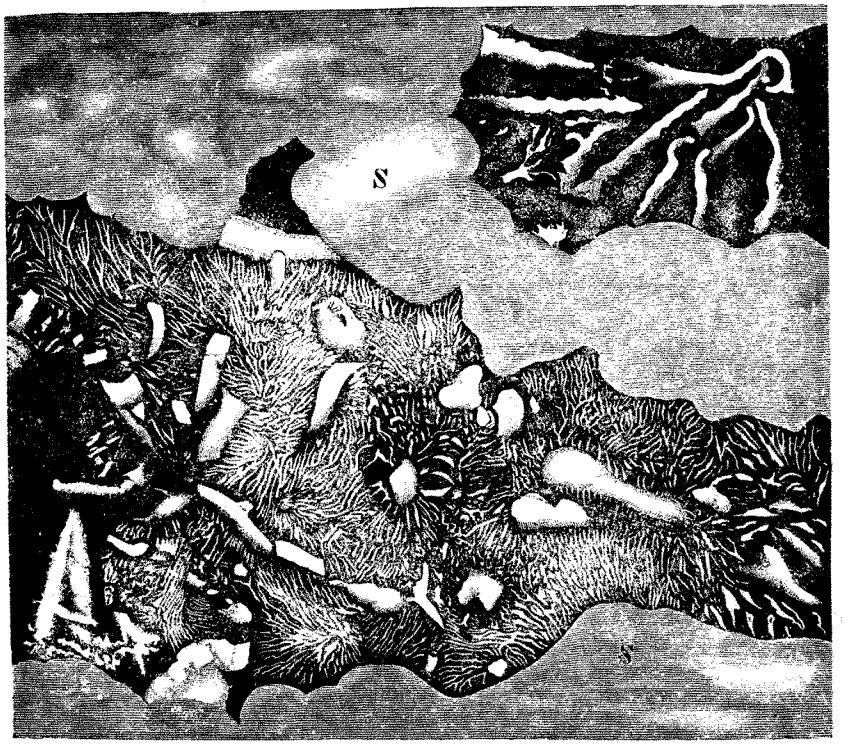
100 years ago

THE eminent zoologist, Dr. Karl Moebius, of Kiel, has recently published a treatise, "Der Bau des *Eozöon canadense* nach eigenen Untersuchungen verglichen mit der Bau der Foraminiferen" ("The Structure of *Eozöon canadense*, according to my own Investigations, compared with the Structure of Foraminifera"), which first appeared in the "Palaeontographica" (vol. xxv.), and was afterwards republished separately. Prof. Moebius inclines entirely towards the view of King and Rowney (*Proc. Roy. Irish Acad.* ser. 1, x. and ser. 2, i.) disputing the organic character of Eozöon. . .



According to Dr. Moebius *Eozöon canadense* consists principally of alternate layers of yellowish green serpentine and whitish limestone. . .

"If the Eozöon pieces from the Laurentian or 'Urgneiss' formation

were really remains of an undoubted foraminifera species, then we should possess in them *certain* proofs that even during the formation of the most ancient strata of the earth's crust living beings occurred, and that the first organisms belonged to the lowest animals, by which biology and geology would have gained two highly important facts. Yet by the scientifically justified elimination of Eozöon from the domain of organic beings it is not proved that during the Laurentian period no living beings existed. Perhaps the graphite of the Urgneiss formation has its origin in organic beings."

Protein methylation in behavioural control mechanisms and in signal transduction

Martin S. Springer*, Michael F. Goy* & Julius Adler

College of Agricultural and Life Sciences, Departments of Biochemistry and Genetics, University of Wisconsin, Madison, Wisconsin 53706

In both prokaryotes and eukaryotes methyl groups can be added to and removed from the carboxyl groups of proteins. Recent work has revealed that these reactions have a role in several behavioural phenomena. The nature of this role has been uncovered in one case—that of bacterial chemotaxis.

AMONG the problems addressed by biologists, one of the most intriguing is that of defining the mechanisms that underlie behaviour at the cellular level. This includes the transduction of one signal into another. For example, sensory stimuli interact with sensory receptors to bring about an alteration in cellular output, neurotransmitters combine with synaptic receptors to change ion fluxes, and hormones affect cell surface receptors to produce responses in target cells. In the past few years it has become apparent that reversible covalent modifications of macromolecules play an important role in some of these mechanisms. The phosphorylation and dephosphorylation of proteins are perhaps the best characterised examples[1-4]. Recently, another class of covalent modification, methylation of protein-carboxyl groups, has been linked to the control of behaviour and to signal transduction in both prokaryotes and eukaryotes. In this article we will summarise the evidence for the involvement of protein methylation in bacterial chemotaxis, a simple behavioural response in which the role of this modification has been characterised in some detail. We will also provide a brief discussion of the evidence linking protein methylation to behaviour in eukaryotes.

The response of bacteria to chemical stimuli

Motile bacteria such as *Escherichia coli* and *Salmonella typhimurium* are attracted by certain chemicals and repelled by others, a phenomenon known as chemotaxis[5-15]. In nature the cells respond to spatial gradients of these chemicals by monitoring concentration as a function of time and reacting to the changes experienced as they swim from one place to another. The bacteria, then, are actually sensitive to temporal changes in chemical concentration[16-18]. In the laboratory it is convenient to provide temporal stimuli directly, by the sudden addition or removal of a chemical[16,17].

Before stimulation, the cells show a pattern of motility characterised by periods of smooth swimming interrupted at random intervals by brief periods of chaotic tumbling[16,19]. Smooth swimming is produced by anticlockwise rotation of the flagella[20], which act as propellers to drive the cells through the surrounding medium[21-23]. Tumbling results when the direction of rotation is reversed[20,24].

When an attractant is added (Fig. 1*a*), the cells respond with a suppression of tumbling[16]. After a lag period, however, the frequency of tumbling returns to the pre-stimulus level[16,25,26]; the cells have in effect become insensitive to the continued presence of the attractant. The initiation of the behavioural response is referred to as sensory excitation and the subsequent loss of sensitivity as sensory adaptation. The adaptation process begins as soon as the attractant is added and proceeds until it reaches completion and terminates the response[26]. The time required for this is a function of the strength of the stimulus (defined by the magnitude of the increase in concentration) and can be many minutes following a large concentration change[16,25,26].

When the attractant is removed, sensitivity is rapidly regained[26], that is, the bacteria can respond again if the attractant is added back. The restoration of sensitivity can be thought of as the inverse of adaptation and is referred to as de-adaptation. A curious asymmetry should be pointed out: the de-adaptation process is very much faster than the corresponding

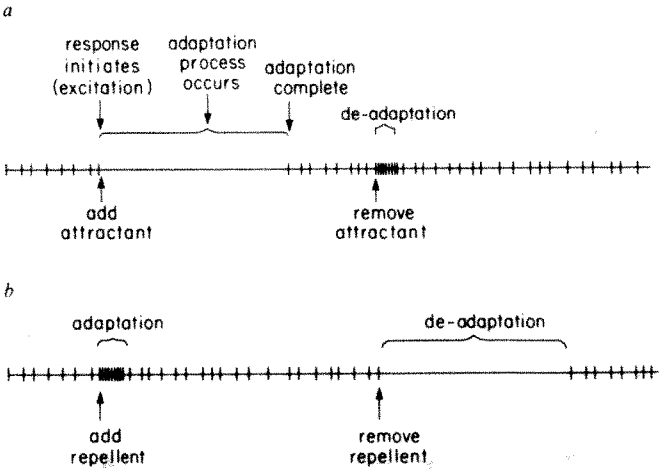

Fig. 1 Schematic representation of temporal responses. Each vertical line represents a tumble. The absence of vertical lines that follows addition of attractant or removal of repellent represents suppression of tumbling, while the increased frequency of lines that follows removal of attractant or addition of repellent represents continuous tumbling. *a*, Effect of attractants; *b*, effect of repellents.

adaptation process, requiring no more than a few seconds even for a large decrease in attractant concentration[16,26]. This asymmetry is indicated in Fig. 1*a*. Note that de-adaptation is accompanied by a brief period of enhanced tumbling[16,26].

Repellents have behavioural effects which by several criteria are opposite to those described for attractants. First, addition of a repellent (like removal of an attractant) results in a short period of increased tumbling, whereas removal of repellent (like addition of an attractant) causes a longer period of suppressed tumbling[17] (Fig. 1*b*). Second, if an attractant and a repellent are added simultaneously the two tend to cancel each other's effects[17,27]. These results suggest that, in terms of the underlying biochemical mechanisms, there is an analogy between the process which follows addition of repellent and that which follows removal of attractant and similarly between removal of repellent and addition of attractant.

The mechanisms that underly these behavioural responses have been analysed by using mutants that are defective in various aspects of chemotaxis. The mutants fall into several classes which can be used to define a pathway of information flow, as shown in Fig. 2. The first class, called specifically non-chemotactic, suffer from lesions in one or another of the different kinds of chemoreceptors[28] that detect specific compounds. These mutants respond normally to most chemicals and lack responses only to those chemicals detected by the receptor that has been affected[28–34]. The second class contains mutants that have lost responsiveness to the chemicals detected by several different kinds of receptor, but that retain responsiveness to compounds detected by the remaining receptors. This class of mutants, known as multiply nonchemotactic mutants, contains three complementation groups, called *tsr*, *tar* and *trg*, which define three major branches of the pathway[35–39] (see Fig. 2). The receptors that feed information through the branch defined by the *tsr* gene are called type I receptors, and those feeding through *tar* and *trg* are called type II and type III, respectively. Ultimately, information from all the receptors is integrated and used to control the direction of rotation of the flagella and consequently the frequency of tumbling, as described above. It is in this final, integrated pathway that a third class of mutants is found. These are the generally non-chemotactic (*che*) mutants; they fall into eight complementation groups[15,28,40,41]. A last class, the non-motile mutants, has lost the ability to synthesise or rotate the flagella[15,42] (Fig. 2).

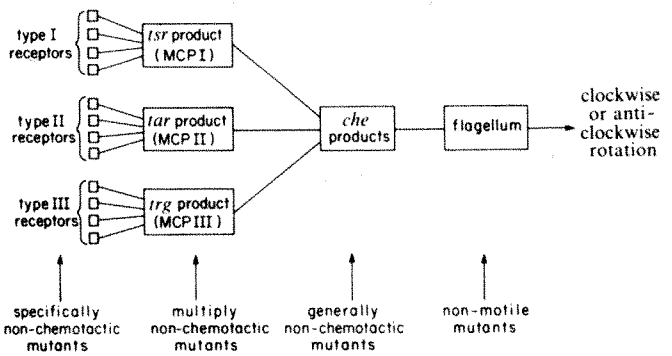

Fig. 2 Information flow during bacterial chemotaxis. The lines represent the pathways of information flow; each of the empty boxes represents a different kind of chemoreceptor. The arrows at the bottom indicate where this flow of information has been interrupted in the various mutants.

Information flow through methylated proteins

Several years ago it was discovered that a protein methylation reaction has an essential role in bacterial chemotaxis[43]. Two criteria were used to demonstrate this. First, the extent of methylation of several cytoplasmic membrane proteins[35,36,39] was shown to be altered by chemicals that elicit a chemotactic response[43]. Second, the methylation reaction failed to occur in some generally non-chemotactic mutants and, when such a mutant was reverted for chemotaxis, methylation simultaneously reappeared[43]. The proteins were therefore called the methyl-accepting chemotaxis proteins (MCPs).

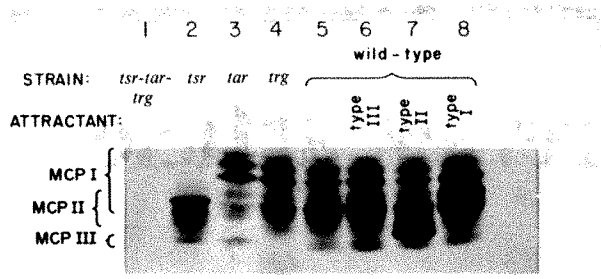

Fig. 3 Methylation patterns from a chemotactically wild-type strain and from *tsr* (lacking MCP I), *tar* (lacking MCP II) and *trg* (lacking MCP III) mutants. Bacteria were incubated with [*Me*-^{3}H]methionine in the presence of a protein synthesis inhibitor, as described previously[53]. The attractants used, D-ribose (5 mM), DL-α-methylaspartate (5 mM) and α-aminoisobutyrate (50 mM), are type III, typeII and type I stimuli, respecnvEqual amounts of protein were layered on a 7% SDS polyacrylamide gel. The fluorographic image shows the region of the gel where proteins of molecular weights 56,000–65,000 are found. The brackets indicate the bands which compose MCP I, MCP II and MCP III. The lower two bands of MCP I and the upper two bands of MCP II overlap[35]. Strains used were AW405, AW518, AW539, AW701 and AW660 for the wild type, *tsr*, *tar*, *trg* and *trs-tar-trg* mutants, respectively.

Where do the MCPs function in the pathway of information flow described above? Three different MCPs have been defined by the three complementation groups of the multiply nonchemotactic mutants[35,36,39]. This is documented in Fig. 3, which shows the methylation patterns obtained by incubating bacteria with [*Me*-^{3}H]methionine (the source of the methyl group). As shown in Fig. 3 (lanes 1–5), the *tsr* mutant lacks a set of methylated bands collectively called MCP I (refs 35, 36), the *tar* mutant a set of bands called MCP II (refs 35, 36) (note that there is some overlap of MCP I and MCP II), and the *trg* mutant a set of bands called MCP III (ref. 39); the triple mutant lacks all these methylated bands[39]. Evidence suggests that *tsr* and *tar* actually code for the MCP I and II polypeptides, respectively[36,44], and by analogy it is thought that *trg* may code for the MCP III polypeptides[39]. Why each of these genes gives rise to more than one polypeptide is not clear, although there is some indication that this results from post-translational modification of the gene products[45].

Information from each of the three different types of receptor (as defined in Fig. 2) causes a change in the level of methylation of the appropriate MCP. Apparently, the cells maintain a basal level of methylation in the absence of external stimuli. If a type I, II or III attractant is added there is a large increase in the level of methylation of the appropriate MCP with little or no increase in the methylation of the other two MCPs[35,36,39,46]. This is shown in Fig. 3, lanes 5–8. As illustrated in Fig. 4*a*, the basal level of methylation of an MCP (defined by the plateau of radioactivity incorporated by cells from labelled methionine in the absence of added stimuli[43,46]) is rapidly increased in response to an attractant until a new plateau is reached. The methylation will remain at this new level as long as the attractant is present, and returns to the basal level only when the attractant is removed[46]. Addition of a repellent, on the other hand, causes a decrease in methylation[46] (Fig. 4*b*), and removal of repellent causes re-methylation (M.S.S. and M.F.G., unpublished); these results might be expected as repellents and attractants have opposite effects on behaviour.

The chemical reactions which are used to regulate the level of methylation of the MCPs are shown in Fig. 5. Methyl groups are transferred from *S*-adenosylmethionine to the MCPs[47] by esterification of the γ-carboxyl group of one or more glutamic acid residues[48,49]. Methyl groups are removed by a reaction in which the final product is methanol[50,51]. Both reactions have been demonstrated in *in vitro* systems[47,50]. A methyl transferase has been partially purified and found to be a soluble protein with

a molecular weight of about 41,000 (ref. 47). An esterase has also been identified; it is a soluble protein and has a molecular weight of about 100,000 (ref. 50).

Involvement of methylation in sensory adaptation

What role do these changes in methylation play in the chemotactic response? This question can be investigated by observing the behaviour of cells in which the methylation reaction has been blocked. The discovery that *cheX* mutants of *E. coli* have the acceptor proteins present in the membrane but lack the ability to methylate them[35,36,43,47] provided an opportunity for this type of experiment. A number of independent *cheX* mutants have been examined: each initiated the appropriate behavioural responses when subjected to attractant and repellent stimuli, but in each the responses were abnormally prolonged[52,53]. For example, wild-type cells typically exhibit a 5-min period of smooth swimming following the addition of the attractant α-aminoisobutyrate (50 mM final concentration) but a *cheX* mutant failed to adapt to this stimulus even after 36 h of exposure[53]. It seems, then, that the process of sensory adaptation is defective in these mutants.

Methylation has also been blocked by starving methionine auxotrophs of methionine and consequently depleting them of

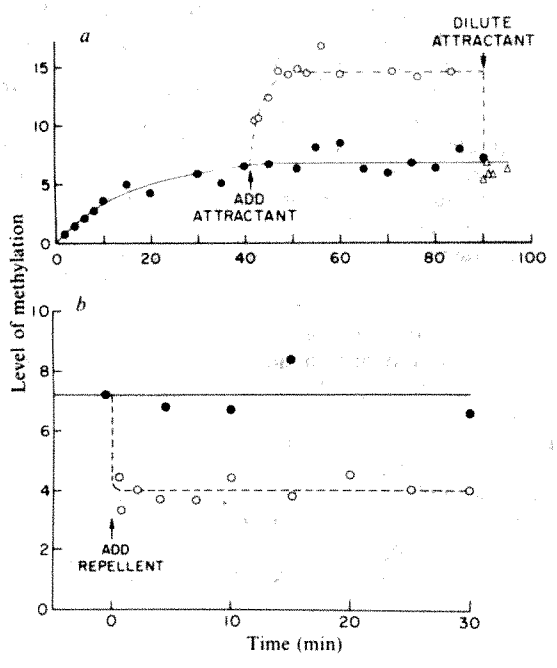

Fig. 4 Effect of chemical stimuli on the methylation of MCP (from ref. 46). Samples were electrophoresed on a 12% SDS polyacrylamide gel. A fluorographic image of the gel was obtained and the MCP region in the developed film scanned with a densitometer. The 'level of methylation' of each sample is the area under the densitometric curve divided by the amount of protein applied to the gel, and is expressed in arbitrary units. The data were obtained by scanning the entire MCP region and thus represent the behaviour of aggregate MCP and not that of any one band. *a*, [*Me*^{3}H]methionine was added at time zero in the presence of a protein synthesis inhibitor. After 40 min incubation the culture was divided in two. One group of cells (○) was stimulated by the addition of the type I attractant α-aminoisobutyrate (50 mM final concentration), the other group of cells (●) received no addition. The concentration of α-aminoisobutyrate was subsequently lowered by diluting the stimulated cells 100-fold into medium containing no α-aminoisobutyrate (△); the first point was obtained 15 s after this dilution. (A 100-fold dilution of stimulated cells into medium containing α-aminoisobutyrate had no effect on the level of methylation.) Similar data have been obtained for type II and type III attractants. *b*, Cells were incubated with [*Me*^{3}H]methionine for 30 min and the culture divided in half. One part received no addition (●) and a mixture of type I repellents was added to the second (○). Zero time refers to the time at which the stimulus was added. The first sample was obtained 20 s after stimulation. When the repellent was removed (at 2 min) by filtration and the cells resuspended in medium containing [*Me*^{3}H]methionine, the level of methylation returned to its initial value 20 min after filtration, the earliest time studied (data not shown, M.S.S. and M.F.G., unpublished).

the methyl donor for the reaction. Cells partially starved of methionine respond to the addition of attractants but do so for abnormally long periods[54,55]. The severity of this adaptation defect increases as the bacteria become further depleted of methionine[55] until finally adaptation fails entirely[56]. Thus, two independent methods of blocking methylation lead to the same conclusion: methylation is involved in the process of sensory adaptation.

The changes in methylation level following addition or removal of stimuli (see Fig. 4) could serve as the biochemical mechanisms which regulate the processes of adaptation and de-adaptation[46,56]. This hypothesis may be summarised as follows: (1) the level of methylation of the MCPs observed before a stimulus is added corresponds to a state in which the cell is fully sensitive to the stimulus; (2) the increase in methylation level that follows the addition of an attractant constitutes the process of adaptation to the attractant; (3) the final level of methylation corresponds to the state of complete adaptation to the attractant, and maintenance of the level corresponds to the maintenance of that state; (4) demethylation, which results from removal of the attractant, constitutes the process of de-adaptation whereby sensitivity is re-established; (5) for repellents, as suggested by the opposite nature of the behavioural responses, the adaptation and de-adaption processes are reversed relative to attractants, so that the decrease in methylation that follows addition of repellent represents the process of adaptation, whereas the increase in methylation that follows its removal corresponds to the process of de-adaptation.

There is considerable evidence to support this proposal. First, the methylation and demethylation reactions show the same asymmetry as the adaptation and de-adaptation processes[16,17,26,46]. Specifically, methylation, like the process of adaptation which follows addition of an attractant, is slow, while demethylation, like the process of de-adaptation which follows removal of an attractant, is fast (Figs 1*a*, 4*a*). This analogy holds true in reverse for repellents. Second, if the methylation reaction actually controls the adaptation process, the cells should respond to an attractant only while the level of methylation is increasing. Data indicate that the time required for the increase in methylation is very similar to that required for adaption[46]. In fact, when two stimuli are compared it is found that the ratio of the length of the responses to these two stimuli is equal to the ratio of the half-times of the changes in methylation induced by the stimuli[46]. Third, there is a striking correlation between the methionine dependency of the behavioural response and the methionine dependency of methylation[46,56]. Adaptation to attractants is methionine dependent, but once a cell has adapted to an attractant it will remain adapted even if methionine is subsequently removed; furthermore, de-adaptation can occur in the absence of methionine[56]. Correspondingly, it has been demonstrated that methylation requires the presence of methionine, but that both maintenance of an attractant-induced level of methylation and demethylation when the attractant is removed do not[46]. Taken together, these observations support the hypothesis that the state of methylation of the MCPs regulates the state of adaptation of the cell.

The control of the level of methylation

As seen in the preceding sections, the methylation and demethylation of the MCPs are carefully regulated. A study of the generally non-chemotactic mutants suggests that the products of some of the *che* genes play a part in the control of these processes. The *che* mutants can be divided into two groups based on their methylation phenotypes.

cheX and *cheB* mutants of *E. coli* (*cheR* and *cheX* of *S. typhimurium*) incorporate virtually no radioactive methyl groups into the MCPs[35,36,43,47]. Present evidence indicates that the product of the *cheX* gene is the methyl transferase[47], and the product of the *cheB* gene is the methyl esterase[50,57]. (Apparently, *cheB* mutants fail to incorporate label into the MCP polypeptides because they are always fully methylated[57]

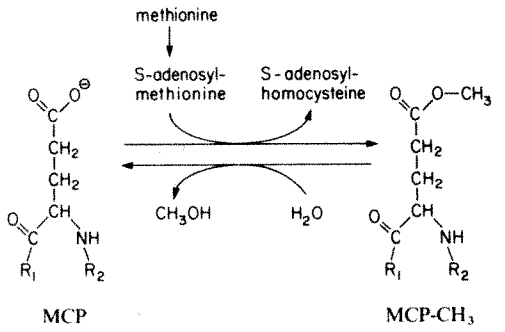

Fig. 5 Protein modification reactions discussed in this article.

and cannot demethylate to provide sites for the incorporation of labelled methyl groups.) Interestingly, lesions in either of these genes affect the methylation of all three MCPs[35,36,43,47,50,57], so the methylating and demethylating enzymes are probably not specific for any single MCP. From biochemical studies[84] it seems that the specificity required to permit a particular stimulus to affect the methylation of only MCP I or MCP II or MCP III results from physical contact between a chemoreceptor and one of the three MCPs, an interaction that alters the ability of that MCP to be methylated or demethylated.

Mutations in the other *che* genes produce strains that do incorporate radioactive methyl groups, although in some cases the amount and/or the distribution of label incorporated into the various MCPs is altered (refs 35, 36, 43, 47 and M.S.S. and M.F.G., unpublished). However, no interpretation of these defects has been formulated, and the functions of the products of these genes remain unknown.

Sensory excitation in bacterial chemotaxis

In the above discussion the chemotactic response has been separated into two processes, called excitation and adaptation. The validity of this separation is demonstrated best by the *cheX* mutants, which become excited in response to stimuli but fail to adapt. Excitation, like adaptation, seems to involve the MCPs[35,36], as mutations in *tsr*, *tar* and *trg* (the genes that apparently code for MCP I, II, and III) produce strains that are defective in excitation of type I, II and III stimuli, respectively[35,36,39,58], and a triple mutant carrying all three lesions is unable to produce an excitatory response to any stimulus tested (C. B. Ball and H. Kondoh, unpublished). However, unlike adaptation, excitation does not involve methylation of the MCPs, as *cheX* mutants, which have the MCPs but cannot methylate them, can still give an excitatory response[52,53]. The molecular details of the excitatory process remain to be elucidated.

A working model for the role of methylation in bacterial chemotaxis

Regulation of the chemotactic response is ultimately manifested as control over whether the flagella rotate in the anticlockwise or clockwise direction and hence whether the cell swims smoothly or tumbles. Some parameter, which we call the rotation regulator, must determine the sense of this rotation. (In previous work this parameter has been called the response regulator or the tumble regulator[9,12,14].)

In our model there are two processes that involve the MCPs: an excitatory process, whose activity changes rapidly when a stimulus is presented, and an adaptational process, whose activity changes slowly (Fig. 6*a*). It is the ratio of these two activities that determines the level of rotation regulator. When the system is at rest (that is, when the cell is not responding to any stimulus) the two processes are balanced so that the rotation regulator is present at a level that allows both smooth swimming and tumbling (see Fig. 6). If an attractant is added, the receptors immediately produce a signal that results in a rapid increase in the activity of the excitatory process, and the level of the rotation regulator rises. The flagella rotate exclusively anticlockwise and tumbling is suppressed (that is sensory excitation occurs). At the same time, the receptor signal also causes a slow increase in the activity of the adaptation process, namely, an increase in the level of methylation of the appropriate MCP. This tends to counteract the effect of the excitational process, and the level of the rotation regulator begins to return to the resting level. Ultimately, when the new plateau level of methylation is reached, the two processes are again in balance, and the level of the rotation regulator has returned to a point that allows both smooth swimming and tumbling (Fig. 6*b*, *c*). The cell has adapted, and the response is terminated. When the attractant is removed, both the excitatory process and the level of methylation fall to their original value. However, the removal of methyl groups lags slightly behind, and there is a brief decrease in the level of the rotation regulator, resulting in a brief tumbling response. Once this is completed the cell has de-adapted and is ready to respond again. (According to this model the response to addition of a repellent would be exactly analogous to the response to removal of an attractant, and removal of repellent would be like addition of attractant.) A molecular interpretation is presented in Fig. 7.

Our model is representative of a class of models which use two competing processes to initiate and terminate behavioural responses[59–61]. Such two-process models have been successfully applied previously to explain the properties of the chemotactic response in bacteria[16,26]. Although our version accounts for most of the phenomena of chemotaxis, including the relationship of methylation to the response, there are several observations which do not fit well into the framework as presented.

The model predicts that *cheX* strains, which do not have the complete apparatus with which to methylate their MCPs[47], should not tumble at all (since the activity of the excitational process should always exceed that of the adaptation process) whereas *cheB* strains, whose MCPs are permanently methylated[50,57], should tumble continuously (since the activity of the adaptation process should always exceed that of the excitational process). Indeed, this is true in most conditions[14,15]. However, *cheX* mutants can be made to tumble by the addition of a repellent[47,52,53] and *cheB* mutants can be made to swim smoothly by addition of an attractant[14]; thus, additional studies of these mutants and/or refinements of the model are required.

Several important questions pertaining to the methylation and demethylation reactions remain unanswered. First, the identity of the rotation regulator has not been established, although evidence has been presented that in *Bacillus subtilis* it may be intracellular calcium ions[62]. Second it remains to be seen how the MCPs function to control the level of the rotation regulator. For example, they could be enzymes that synthesise the rotation regulator, or they could be ion gates that control the

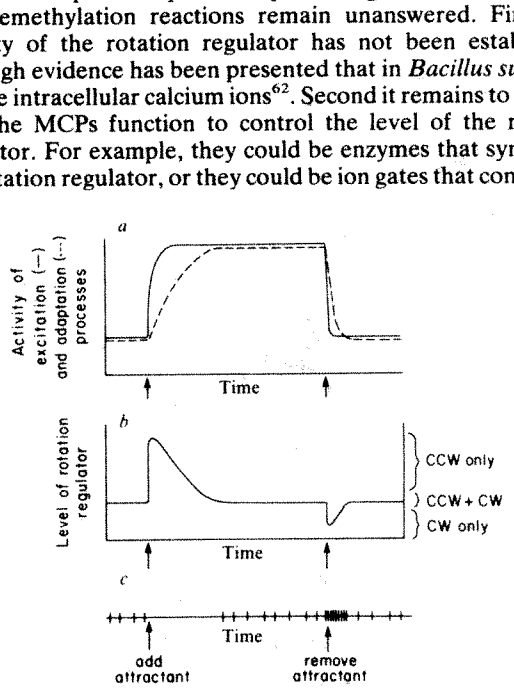

Fig. 6 Model for the role of methylation in bacterial chemotaxis. CCW stands for anticlockwise rotation of the flagella, which corresponds to smooth swimming, and CW stands for clockwise rotation, which corresponds to tumbling. Figure 6*c* is repeated from Fig. 1*a*. See text for explanation. (Increase in level of rotation regulator producing anticlockwise rotation is an arbitrary choice; it could just as well be a decrease.)

level of an ion which serves as the regulator. Third, we do not know the details of how the binding of stimulatory chemicals to chemoreceptors influences the methylation of the MCPs.

Despite the work that remains to be done, the identification and characterisation of the methylation and demethylation reactions represent a significant step forward in the effort to understand how bacteria transduce sensory signals into a behavioural response.

Carboxyl methylation in eukaryotic systems

The existence of protein-carboxyl methylation in eukaryotes was known before the discovery of the reaction in bacteria[63-71]. However, its function in eukaryotic cells is only now beginning to be understood. This reaction seems to regulate several processes, some behavioural in nature. The one most closely related to the bacterial system described above is leukocyte chemotaxis.

A number of different types of white blood cells use chemotaxis in the initial phase of their response to infectious or inflammatory agents[72]. Many natural and synthetic substances act as attractants for these cells[73]. During the past two years several groups have investigated the possibility that a carboxyl methylation reaction might be involved in this phenomenon[74,75]. Measurement of the methanol released when carboxyl-methyl esters are hydrolysed at high pH[74] has shown that the addition of an attractant to leukocytes causes a perturbation of the level of carboxyl methylation[74], and that both the behavioural response and the change in carboxyl methylation can be prevented by the prior addition of an attractant antagonist[76]. Furthermore, it has been found that incubation of leukocytes with compounds that inhibit methylation reactions in general[75,77,78] blocks the behavioural response[75,79]. Thus methylation seems to be involved in the sensory response of leukocytes.

It is interesting that methyl-acceptor proteins and a methylating activity are also found in high concentrations in mammalian testis, spermatazoa and spermatids[66,71,80]. It is possible that here, too, there is involvement of protein methylation in a chemotactic response. Although there is at present no evidence for or against the idea, it may be that mammalian spermatazoa use chemotaxis as an aid to fertilisation; certainly, this occurs in simpler animals[81].

Protein-carboxyl methylation also plays a part in neural and endocrine functions, as indicated by the following results. (1) Protein-carboxyl methylase is found in most mammalian organs but most abundantly in nervous tissue and endocrine glands, for example brain and pituitary[66,70,71]. Methyl-acceptor proteins are also widely distributed, the pituitary gland being the richest source[70,71]. (2) The methylating enzyme is apparently transported down axons and occurs in synaptosomal preparations[71]. A function at the synapse is indicated by the fact that synaptosomes from the hypothalamus undergo changes in the level of methylation following depolarisation[82]. (3) Stimulation of the adrenal medulla, which results in the secretion of catecholamines, produces an increase in methylating activity[76,83]. When methylation is blocked by an inhibitor, secretion does not occur[76]. (4) In the parotid gland β-adrenergic stimulation, which releases amylase, is accompanied by an increase in the level of methylation of methyl acceptor proteins[80].

Taken together, these results suggest that some of the functions of carboxyl methylation in eukaryotes, as in prokaryotes, concern signal transduction and the control of behaviour at the cellular level.

Conclusion

The methylation and demethylation of protein-carboxyl groups are reactions which may play important parts in the regulation of cellular activities. Protein-carboxyl methylation has already been implicated in several behavioural control mechanisms in a variety of prokaryotes and eukaryotes. That the widespread occurrence of this reaction has only recently been recognised is due at least in part to the lability of carboxyl esters which hinders their identification by usual analytical techniques. With improved methodology protein-carboxyl methylation may be found as ubiquitously as the better known protein phosphorylation reactions.

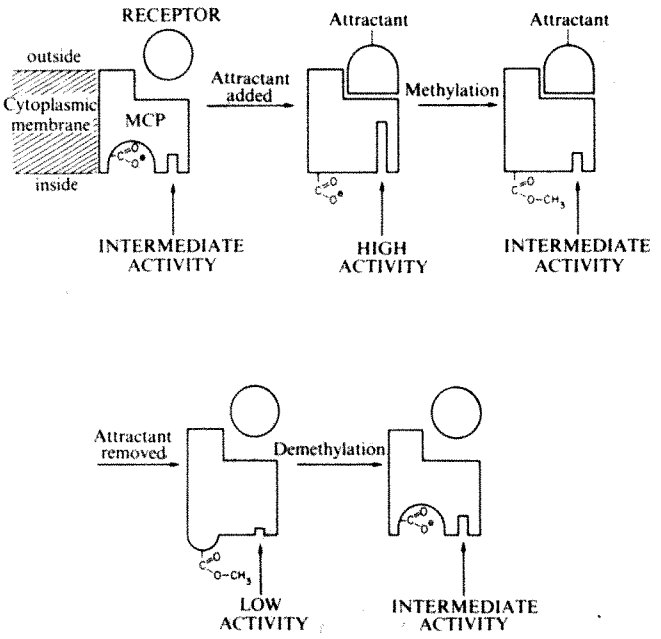

Fig. 7 Speculative molecular model for effect of attractant on the activity of MCP. This activity (ability to generate rotation regulator) is indicated in the figure at various points in the response. In the unstimulated state (top left) MCP has intermediate activity leading to an intermediate level of rotation regulator, and thus both anticlockwise and clockwise rotation can occur (see Fig. 6). When the attractant is added (top centre), it binds to the chemoreceptor and brings about a physical interaction between the receptor and the appropriate MCP. This has two effects: (1) via the excitation process, there is a rapid increase in activity and thus a rise in the level of rotation regulator, so that only anticlockwise rotation occurs; and (2) carboxyl groups become exposed and available for methylation. Slowly methylation then takes place (top right) and causes the activity to return to the intermediate level; thus adaptation occurs. Removal of attractant (bottom left) decreases the activity of MCP; this leads to a decrease in the level of rotation regulator and thereby produces clockwise rotation. Demethylation (bottom right) restores the activity to the unstimulated level. As discussed in the text, neither the nature of the rotation regulator nor the means of its generation by MCP is known. The model shows several features which have been experimentally determined. First, MCP is believed to span the cytoplasmic membrane: interaction of chemical stimuli with chemoreceptors must take place on the outside of the cytoplasmic membrane, and at least some of the receptors are found in the periplasm (the space between the cytoplasmic membrane and the cell wall)[8]; methylation and demethylation must take place on the inner surface of the cytoplasmic membrane, since the enzymes that catalyse these reactions are cytoplasmic[47,50]. Second, upon interaction with ligands, conformational changes in chemoreceptors have been described[85,86]; these observations have been used previously to postulate a ligand-induced conformational change as an obligatory first step prior to the interaction of receptor with subsequent components of the chemotaxis machinery[87]. Third, chemoreceptors appear to interact with MCP directly[84].

Bacteria such as *E. coli* and *S. typhimurium* offer a favourable system for the study of the relationship of protein methylation to behaviour, because these organisms are relatively simple and well characterised both biochemically and genetically. From studies of sensory transduction in bacteria a set of facts and concepts may emerge that is generally applicable to our understanding of the phenomena that underlie behaviour and signal transduction in higher organisms, as evolution seems to have conserved at least some of the biochemical mechanisms involved.

A general riftward younging of surficial volcanic units is a feature of the Addis Ababa sector of the Ethiopian rift valley. The narrowing of the volcanic zone with time is due to crustal necking and topographical control.

THE development of continental rift valleys can be accompanied by a progressive narrowing of the zone of tectonism and volcanism as crustal thinning proceeds[1]. In the Ethiopian rift valley, this phenomenon is difficult to discern owing to voluminous cover from Quaternary rhyolitic ash-flow and air-fall tuff eruptions. However, the complex and perhaps atypical Addis Ababa embayment[2] reveals disconnected exposures of older volcanic units with an overall gentle southeastwards dip towards the rift axis[3–12]. This embayed sector of the western margin of the rift has developed as a broad downwarp lacking any major escarpment; although faulting is common, it is limited to block tilting with associated downthrows to the south-east of tens of metres[2,8].

We review here radiometric ages of volcanic rocks along a 100-km-wide swathe, south-east from the Abbay (Blue Nile) basin via Addis Ababa on the rift margin to the rift floor axis at

Table 1 K–Ar age determinations on volcanic samples from the northwestern sector of the Addis Ababa–rift floor traverse

Sample	Locality	Lat (grad N)	Long (grad E)	Analysed portion	% K_2O	Vol ^{40}Ar ($\times 10^{-4}$ mm^3 g^{-1})	% atmospheric ^{40}Ar	Age (Myr)
Aphanitic basalt (2211)	19 road Km N. of Addis Ababa	10.17	43.06	Whole-rock	1.47	11.17 10.65	56.6 13.3	22.8 ± 1.5
Porphyritic trachyte (ENT)	North side Entoto, 5 km north of Addis Ababa	10.13	43.07	Felspar	5.31	38.01 37.86	44.6 30.9	22.0 ± 0.8
Olivine basalt (2213)	North–Central Addis Ababa	10.07	43.07	Whole-rock	0.72	1.69 1.83	65.5 64.6	7.5 ± 0.6
Basalt (2214)	Northeastern Addis Ababa	10.06	43.09	Whole-rock	0.94	1.95 2.09	64.8 68.2	6.6 ± 0.5
Basalt (2215)	Southwestern Addis Ababa	9.995	43.010	Whole-rock	3.07	3.71	37.5	3.7 ± 0.4
Fiammé-rich welded tuff (A1)	Eastern Addis Ababa	10.020	43.080	Feldspar	1.56	2.61 2.56	80.4 92.9	5.11 ± 0.4
Welded tuff (A2)	Eastern Addis Ababa	10.020	43.085	Felspar	6.28	6.30 6.92	54.7 70.3	3.26 ± 0.1
Felsphyric basalt (2207)	South side Mr Yerer	9.87	43.30	Whole-rock	2.28	2.60	31.3	3.5 ± 0.4
Felsphyric basalt (2207)	South side Mt Yerer	9.87	43.30	Feldspar	0.79	1.00	78.7	3.9 ± 0.4
Trachyte (2208)	South side Mt Yerer	9.87	43.30	Feldspar	3.67	4.34	41.6	3.7 ± 0.4
Rhyolite (2209)	South side Mt Yerer	9.87	43.30	Feldspar	5.08	5.35	69.2	3.3 ± 0.4
Porphyritic rhyolite (MEN)	Mt Menegasha tholoid	10.04	42.87	Feldspar	5.75	5.76 5.70	55.6 44.2	3.09 ± 0.12
Porphyritic trachyte (Z1)	Northeastern base of Mt Zukwala	9.51	43.195	Feldspar	4.14	1.64 1.79	80.4 96.1	1.28 ± 0.15
Porphyritic trachyte (Z2)	Half-way up northeastern side Mt Zukwala	9.50	43.185	Feldspar	5.52	1.57 1.71	80.9 79.8	0.92 ± 0.04
Porphyritic trachyte (Z3)	North rim of Zukwala crater	9.493	43.170	Feldspar	5.40	1.41 1.54	88.1 90.6	0.85 ± 0.05

Samples collected by W.H.M., analysed by D.C.R.
$\lambda_e = 0.581 \times 10^{-10}$ yr^{-1}; $\lambda_\beta = 4.962 \times 10^{-10}$ yr^{-1}; $^{40}K/K = 1.167 \times 10^{-2}$ atom %.

Wolenchiti (Fig. 1), and include 33 new K–Ar age determinations on samples critically selected for their position along the rift transect.

Plateau sequence

The plateau basalt sequence exposed along the Abbay gorge road section, 150 km north-west of Addis Ababa, is observed in tributary canyons to thicken southeastwards. The Abbay basalts have yielded K–Ar ages ranging from 27.9 Myr (basal flow) to 24.0 Myr (top flow)[13]. These data are consistent with values obtained by Zanettin and coworkers[9] on equivalent basalts and a rhyolitic ignimbrite from the upper reaches of the Mugher tributary, but are appreciably older than the 22.1–20.2 Myr age-range obtained by Jones[14] on the same Mugher basalt flows. Maximum ages of 29 Myr have been obtained for basalts from the opposing, eastern shoulder of the rift valley[11,12].

On the 2,600 m plateau immediately north of Addis Ababa, the top flood basalt at Sululta yields an apparent age of 22.8 Myr (Table 1), conforming with the Abbay basalt ages and the observed addition of intervening, less far-travelled flows derived from the rift-margin sources[15]. Basalts (~13 Myr old) of the Gorfu Mts volcanic centre[9] are built on the plateau.

Embracing Addis Ababa, the arc of the Entotto hills is formed of gently north-dipping comenditic lavas and obsidian-rich tuffs overlying related olivine trachytes[16,17]. Our date of 22.0 Myr for a northern Entotto lava is concordant with a previous 22.6 Myr age for a southwestern Entotto comendite[9]. These early Miocene silicic volcanics may represent a localised terminal episode to massive Oligocene fissure–basalt activity in the Addis Ababa region, but their stratigraphic relations to the Sululta basalts immediately to the north are not exposed because of a faulted contact. The only other silicic rocks of known similar age occur near the bottom of the Kassam gorge within the rift valley, 40 km east of Entotto, where separate investigations have produced radiometric ages in moderate agreement. Justin-Visentin *et al.*[9] obtained an age of 23.9 Myr, and Rex *et al.*[18] an age of 21.4 Myr for the lowermost silicic ignimbrite within the exposed 1,000 m thick Kassam basalt section. (The base of the basalt pile farther down the Kassam gorge has not been sought since Francaviglia's provocative identification there of a restricted window of unfossiliferous, supposedly Mesozoic sediments[19].) The available evidence for early Miocene silicic volcanism in the Addis Ababa region suggests an isolated centre at Entotto, with erupta thinning both riftwards and plateauwards: this centre was later strongly upfaulted as a NE–SW trending horst at the margin of the developing rift.

Above the lower basalts of the Kassam gorge, a 100 m thick trachytic bed at 2,100–2,200 m elevation in the northwestern wall has yielded an age of 16.0 Myr, suggesting a downwarped equivalent to plateau-surface (2,800 m) outcrops in the Debra Berhan region, 60 km farther north-east[9]. Thin rhyolitic ignimbrites of the upper Kassam and Shano area (Fig. 1), with ages in the 13–11 Myr bracket, interdigitate with basalts of the Gorfu and Meghezez piles[9], and on the opposing, eastern side of the rift valley, ignimbrites of the same age-range form the 'main silicic formation', up to 300 m in thickness[20].

In the environs of Addis Ababa, the oldest visible rocks post-dating the Entotto rhyolites are alkali olivine basalts lapping the southern flanks of the Entotto horst[4,21]. These very localised basalts yield ages clustering around 7 Myr (Table 1 and ref. 22), and seem to have no time/composition equivalents except on the opposing, eastern shoulder of the rift valley[11]. However, thin but widespread rhyolitic ignimbrites that occur along the plateau margin north-east of Addis Ababa yield ages in a broad 9.2–7.9 Myr range[9].

In Addis Ababa town itself, the north-east-trending Filwoha fault separates, to the north, the 7 Myr-old basalts here overlain by pantelleritic welded tuffs from strongly welded trachytic tuffs to the south. The latter yield apparent ages of 5.1 and 3.3 Myr (Table 1). These ages overlap with the periods of activity of two important trachyte volcanoes: Wachacha, 15 km west of Addis Ababa, and Yerer, 25 km south-east of Addis Ababa (Fig. 1). Wachacha erupted a terminal lava phase (thick biotite–anorthoclase trachyte flows) dated at 4.6 Myr[9,23]. Isolated patches of welded tuff in the Sululta region, dated at 5.4 Myr[9], as well as the

5.1 Myr welded tuff in Addis Ababa, were probably derived from the Wachacha centre before the Entotto and Filwoha faulting. Likewise, welded tuff exposed in the Akaki river canyon, 25 km south of Addis Ababa and dated at 5.3 Myr, was probably derived from Furi, a satellite of Wachacha.

Yerer volcano lacks the lava cap featuring Wachacha, and its more bare aspect belies the clustering of K–Ar ages at 3.6 Myr (ref. 24 and Table 1). The succession at Yerer is[25]:

(4) NW–SE trending basaltic and subordinate trachytic dykes
(3) Vesicular porphyritic basalts (<20 m), flanking 2
(2) Thick trachytic agglomeratic tuffs and subordinate lavas
(1) Massive welded tuffs

In Table 1, the rhyolite and trachyte ages of 3.3 and 3.7 Myr belong to unit (2), and the basalt ages of 3.5 (whole-rock) and 3.9 (plagioclase) Myr to unit (3). A tendency for ^{40}Ar migration into plagioclase phenocrysts of Ethiopian rift basalts has been detected by J.G.M. (unpublished data). Contemporaneous activity formed the isolated Managasha tholoid on the northern flanks of Wachacha volcano, but extensive volcanism was now migrating south-east towards the axis of the proto-rift.

For the sector between Bishoftu and Mojjo (respectively 45 and 70 km south-east of Addis Ababa) no radiometric ages are available. In contrast to the Addis Ababa–Bishoftu sector, where NE–SW faulting upthrown north-west exposes units derived from Yerer, Wachacha and superimposed end Pliocene–Pleistocene basalt cones[22,25], exposures on the plains south-east of Bishoftu are restricted to small silicic centres and young Quaternary basalt cones associated with the Bishoftu maars[25,26]. At the Mojjo River canyon, Pleistocene volcaniclastic and diatomaceous sediments a few metres thick lie on 20 m+ of ignimbrite, but thicken riftwards to 15 m+ (base not seen) in the Melka Lemi canyon 3 km east of Mojjo[27,28].

At Tedi village, 5 km east of Mojjo, the Gadamsa segment of the Wonji fault belt (WFB) is encountered, a zone of closely-spaced, anastomosing normal faulting[29,30]. The WBF here is 10 km wide and comprises some 12 strip-like blocks, each 700–1,000 m wide, that are tilted down to the ESE at 2–3 grads dips. The separating faults trend NNE and have upthrows to the east averaging about 15 m. However, throws of up to 100 m are responsible for narrow horsts at the margins of the fault belt. The summary stratigraphy within the WFB here is:

(3) Weakly-welded tuff, thickening and more crystal-rich eastwards (2–4 m)
(2) Massive pumiceous sediments with occasional well-bedded sub-units and palaeosols (10–20 m)
(1) Strongly welded tuff, base not exposed (55 m+)

Unit (1), exposed also in the Mojjo River canyon, is presumed to have been derived from the Mukie volcanic centre 15 km north of Adama (Fig. 1). Unit (2) thickens both east and west, away from the higher topography of the WFB in the Mojjo–Adama sector. On the eastern side of the WFB, feldspar-phyric basalts are interbedded near the top of unit (2). They were derived from sources aligned along the subsequently faulted western margin of the Adama graben[30], although basaltic eruptions continued within the Adama graben after the deposition of unit (3). Unit (3) resembles unit (2) in being thinner or absent from the higher blocks and horsts of the WFB, but additionally thins out eastwards to zero.

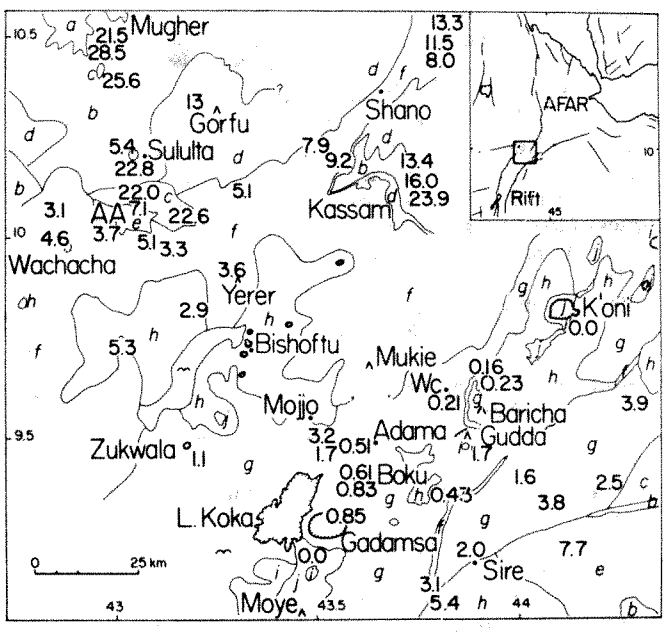

Fig. 1 Chronostratigraphic map of the Addis Ababa region and northern sector of the Ethiopian rift. Numbers are K–Ar ages in Myr. The lettered formations are: *a*, Mesozoic sediments; *b*, plateau basalts (older than 22 Myr); *c*, silicic lavas and tuffs (23–21 Myr); *d*, shield basalts and subordinate rhyolites (16–13 Myr); *e*, olivine basalts (8–6 Myr); *f*, ignimbrites and lavas (11–3 Myr); *g*, ignimbrites (<3 Myr); *h*, olivine basalts (<3 Myr); *i*, Holocene obsidian flows; *j*, Holocene mafic lavas. AA, Addis Ababa; Wc, Wolenchiti. The detailed fault pattern is omitted. Latitude and longitude in grads provide scale; 1 grad latitude equals 100 km.

New K–Ar dates for the WFB transect

We present four new K–Ar dates for this WFB transect (Table 2). Unit (3), sampled from the eastern foot of the Kimbibit horst[22,29], yielded an apparent age of 0.51 Myr. The basalt flow interbedded in unit (2) was sampled from the 'Stegosaur' horst overlooking the Adama graben, and yielded an apparent age of 0.61 Myr identical with that of a small olivine basalt flow lapping Gara Boku, 7 km farther south-east. Unit (1) was sampled 4 km east of Tedi and yielded an apparent age of 1.7 Myr, coeval with major silicic volcanism at Boseti Gudda volcano (on the Boseti segment of the WFB, east of Adama) and shield volcanism on the future eastern shoulder of the rift valley[11,12,31]. However, older rocks floor the rift under the Gadamsa WFB segment, according to the age of porphyritic comenditic obsidian forming the Gara Mariam horst at Tedi (Table 2). Our new date of 3.2 Myr revises previous values for this tholoid[22], and proves activity contemporaneous with Yerer and at the eastern, Siri margin of the rift[11,12]. Gara Mariam, like Entotto, is a discrete silicic igneous centre that has since been upfaulted among younger rocks, in response to isostatic forces acting at the margin of a tensional zone.

Gadamsa volcano with a 10-km-diameter caldera lies on the Gadamsa segment of the WFB some 20 km SSW of Adama[32]. An age of 0.85 Myr (Table 2) pinpoints the middle period of build-up of the Gadamsa cone. One surprise of our dating program is that an indistinguishable age, 0.83 Myr, applies to a late-stage obsidian lava from the similar-sized Boku caldera situated midway between Gadamsa and Adama (Fig. 1). Boku caldera is so severely broken that it required satellite imagery for its initial recognition[29,32]. It seems that the caldera–cone diameter ratio at Boku was probably close enough to unity that caldera collapse facilitated the destruction of the greater part of the remnant cone.

Zukwala volcano, 30 km north-west of Gadamsa, lies on an isolated (non-WFB) volcanotectonic line that projects NNE via a Holocene basalt lava cone to the Bishoftu maars[33]. The Zukwala trachytes yield a progressive sequence of ages, from 1.28 Myr for a basal exposed flow to 0.85 Myr for a crater rim flow (Table 1).

The Boseti segment of the en-echelon WFB is encountered east of Adama. The geology of this area is dominated by Boseti Gudda volcano[29,34], where a caldera is largely buried by a subsequent high cone of pantelleritic tuffs, pumice and subordinate lavas. Morbidelli *et al.*[11] obtained a K–Ar age of 1.6 Myr for a near-summit lava, but the fresh morphology of satellite cones and flows on the southern slopes of Boseti Gudda shows that parasitic activity continued into recent times. Boseti Gudda, and its comenditic neighbour Boseti Baricha immediately to the

Samples collected by P.M., analysed by J.G.M.
Constants as for Table 1.

north, lie on a line of major crustal fracturing from which mildly alkaline olivine basalts have erupted[34,35]. An extensive such flow sampled 2 km south of Bofa on the southern flank of Boseti Gudda yields an apparent age of 0.44 Myr (Table 2). Perfectly preserved end-Pleistocene cinder cones lie on a basalt fissure line displaced 7 km west from the Bofa–Boseti line[35,36].

On the lower western flanks of Boseti Baricha, the Jinjimma olivine trachyte cone issued a flow which we date at 0.21 Myr, consistent with rather well-preserved morphology[29,35]. The cone has been broken by a NNE-trending fault with an upthrow of ~200 m to the west[29], and smaller parallel faults cut the flow. 6 km farther NNE along this active and intensely sliced zone, trachyte obsidians from the spectacularly faulted and fissured Gara Chisa dome yield ages of 0.23 Myr (northern flank) and 0.16 Myr (summit). The Jinjimma–Chisa line of silicic volcanism thus seems to represent a recent westward side-stepping of silicic volcanism in the WFB. However, young mafic eruptions have continued from the main Boseti alignment, most notably voluminous and highly fluid mugearite flows from the col between Gudda and Baricha[34,35]. Our date of 0.36 Myr for a mugearite specimen from Sogido (Table 2) is certainly too old, as these lavas are stratigraphically younger than flanking obsidian flows from Gara Chisa dated at 0.23 Myr. If excess argon occurs at a level common to many Ethiopian rift basalts[37], then an age of 0.23 Myr would be indicated.

Conclusions

In summary, a general riftward younging of surficial volcanic units is a clear feature of the Addis Ababa sector of the Ethiopian rift valley. Exceptions to this pattern are interesting but second-order phenomena, such as the Zukwala volcanic line along the western margin of the rift, and young centres on the plateau west of Addis Ababa[27,40]. The younging phenomenon is consonant with the broad crustal downwarp developed between the Abbay basin and the rift axis[38,39]. Downwarping towards the future site of the rift valley began in late Jurassic time, continued throughout Oligocene–Miocene flood basalt extrusion, and was active together with block faulting during early–mid Pleistocene differential uplift of the Ethiopian plateaux.

But does the progressive confining of rift volcanism with time merely reflect topographic control, from deepening of the proto-rift trough that culminated in mid-Pleistocene downfaulting of the rift valley? Or does it reflect a fundamental control of eruptive sites from processes of crustal necking and separation[41]? Plate tectonic analysis of the Afar triple-junction has led to two estimates of Ethiopian rift 'opening' of 65 km (ref. 42) and 40 km (ref. 43). The latter better fits the geological and geophysical constraints. Geologically, there is continuous exposure of ~24 Myr-old volcanic units for at least 20 km riftwards down the Kassam gorge; and at the southern end of the Ethiopian rift, the floor is severely faulted but exposes Precambrian rocks[44]. Geophysically, crustal thickening occurs east across the Ethiopian plateau to Addis Ababa and possibly as far as Bishoftu[45,46]; however, gravity modelling of the crust within the rift implies drastic thinning and an extension of 25–40 km if stoping processes are ruled out[47,48].

Elucidation of the cause of progressive confinement is complicated by the changing character of rift volcanism with time, from voluminous flood basalt lavas through episodic but intimate mafic and silicic eruptions, to relatively voluminous silicic tuffs. Furthermore, earlier eruptive sites are now hidden. We conclude, on the basis of our work together with known geophysical constraints, that narrowing of the volcanic zone in the Ethiopian rift with time is due partly to crustal necking, but more significantly to topographical control[49].

P.M. thanks R. G. H. Raynolds and Mikael Tesfaye for assistance with field sampling. This work has been partly financed by NERC and by Smithsonian Institution SRF grant 71702113.

Sequences at the somatic recombination sites of immunoglobulin light-chain genes

Hitoshi Sakano, Konrad Hüppi, Günther Heinrich & Susumu Tonegawa

Basel Institute for Immunology, 487 Grenzacherstrasse, Postfach, CH-4005 Basel, Switzerland

The entire nucleotide sequence of a 1.7-kilobase embryonic DNA fragment containing five joining (J) DNA segments for mouse immunoglobulin κ chain gene has been determined. Each J DNA segment can encode amino acid residues 96–108. Comparison of one of the five J DNA sequences with those of an embryonic variable (V) gene and a complete κ chain gene permitted localisation of a precise recombination site. The 5′-flanking regions of J DNA segments could form an inverted stem structure with the 3′-non-coding region of embryonic V genes. This hypothetical structure and gel-blotting analysis of total embryo and myeloma DNA suggest that the somatic recombination may be accompanied by excision of an entire DNA segment between a V gene and a J DNA segment. Antibody diversity may in part be generated by modulation of the precise recombination sites.

IMMUNOGLOBULIN polypeptide chains consist of two regions, the amino-terminal half, called the variable (V) region, and the carboxyl-terminal half, called the constant (C) region. In embryonic cells the two regions are encoded in widely separated DNA segments. During differentiation of bone marrow-derived (B) lymphocytes the two DNA segments are brought into proximity by site-specific recombination, producing a single transcription unit[1,2].

The details of the sequence organisation before and after recombination have been worked out in the mouse λI light-chain system by analysis of cloned DNA fragments [3,4]. These studies revealed that in embryo cells the conventionally defined V region is itself encoded in two separate DNA segments, one (V DNA) coding for the major part of the V region (residues 1–97) and the other (J DNA) coding for the rest of the V region (residues 98–109). Although the distance between the V and the C DNA segments is unknown, the J DNA segment has been mapped at 1.2 kilobases towards the 5′-side, relative to the direction of transcription, of the C DNA segment.

Somatic recombination takes place at the 3′-end of the V DNA segment and the 5′-end of the J DNA segment. Consequently, in a λI chain synthesising B lymphocytes or plasma cells, although the DNA segment coding for the entire V region is much closer to the C DNA segment, the two DNA segments are still separated by 1.2 kilobases. This untranslated sequence (intron)[5] separating the J and C DNA segments is thought to be removed at the RNA level by a process called splicing[6,7]. Hence, the J DNA segment and its flanking sequences seem to be involved in two key processes essential for the expression of an immunoglobulin gene: site-specific V–J recombination and J–C splicing[3].

More recently, we have analysed the organisation of mouse κ light-chain genes[8,9]. A comparison of the sequence organisation of the two light-chain gene systems revealed both common and differing features. As in the λ gene system, a secreted κ chain is encoded in three separate DNA segments in embryonic cells, Vκ, Jκ and Cκ. In addition, somatic recombination takes place between embryonic Vκ and Jκ DNA segments. However, unlike the λI gene system, the mouse genome contains multiple Vκ and Jκ DNA segments, the latter being clustered in the vicinity of a single copy of the Cκ DNA segment.

For a better understanding of the structural features of the recombination sites we have determined the nucleotide sequences of the Jκ cluster as well as the 3′-end region of an embryonic Vκ DNA. This information, in addition to Southern

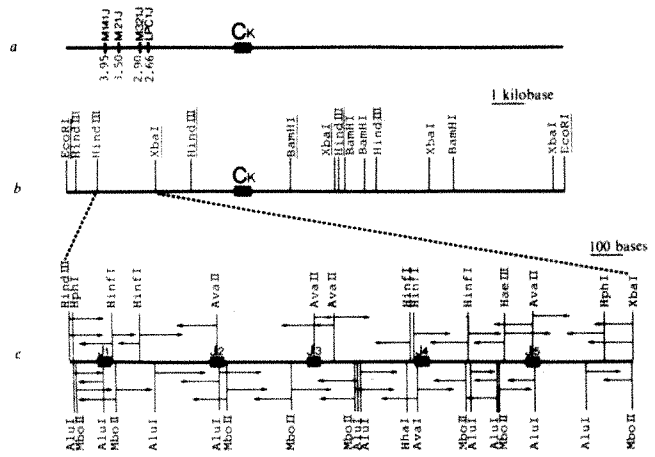

Fig. 1 *a*, R-loop map of the 15-kilobase insert of Ig146. κ mRNAs from four different myelomas, MOPC141, MOPC21, MOPC321 and LPC1, were individually annealed with the Ig146 *Eco*RI DNA fragment and the position of the corresponding J DNA segment was determined by electron microscopy (see ref. 9 for details). The bars represent the J DNA segments. The numbers indicate their distance from the Cκ DNA segment. *b*, Restriction enzyme cleavage map of the 15-kilobase insert of Ig146. The whole Ig146 phage DNA and the purified vector phage (λWES)[30] arm DNA (1 μg each) were digested either with one of the indicated enzymes or with that enzyme plus *Eco*RI, and separated by electrophoresis in a 1% agarose gel. Comparison of the single and double digestion patterns allowed localisation of the outermost cleavage sites of each enzyme on the 15-kilobase insert. Other cleavage sites were determined by comparing the pattern obtained by a single enzyme digestion (enzyme A or B) with that obtained by a double enzyme digestion (enzyme A plus B). The position of the Cκ DNA segment relative to the underlined cleavage sites was determined by examination of R-loop structures formed between MOPC321 κ mRNA and the Ig146 DNA predigested with the corresponding enzyme. *c*, Sequencing strategy and a restriction map of the 1.7-kilobase *Hin*dIII–*Xba*I fragment. The rightmost cleavage site of each enzyme was identified by comparing the cleavage pattern of the 1.7-kilobase *Hin*dIII–*Xba*I fragment with that of the 2.7-kilobase *Hin*dIII–*Hin*dIII fragment. For determination of additional cleavage sites the *Hin*dIII–*Xba*I fragment was end-labelled with [γ-^{32}P]ATP and separated into two fragments by *Hha*I digestion followed by electrophoresis. The purified *Hin*dIII–*Hha*I and *Hha*I–*Xba*I fragments were digested with one of the indicated enzymes in limited conditions and the cleavage sites were deduced according to the method of Smith and Birnstiel[31]. Horizontal arrows indicate the direction and the extent of sequence determination. The boxes indicate positions of J DNA segments as determined by the nucleotide sequence analysis.

gel-blotting experiments, was used to formulate a model for somatic recombination. We also discuss V–J joining with respect to generation of antibody diversity and evolution of immunoglobulin genes.

Sequencing strategy for the J DNA cluster

We have previously reported cloning of a 15-kilobase embryonic DNA fragment (clone Ig146κ) containing a single Cκ DNA copy[8]. Analyses of R-loops formed between this DNA fragment and five different κ mRNAs isolated from myelomas MOPC141, MOPC21, MOPC321, LPC1 and HOPC8 identified at least four different J DNA segments (HOPC8 J and LPC1 J may be identical) in the region 2.5–4.0 kilobases to the left of the Cκ DNA segment (Fig. 1*a*)[9]. To determine the nucleotide sequence of this region, we first constructed a restriction map of the 15-kilobase Ig146κ DNA using restriction enzymes *Hin*dIII, *Bam*HI, and *Xba*I (Fig. 1*b*). The position of the Cκ DNA segment in the restriction map was determined by examining R-loops formed between MOPC321κ mRNA and the Ig146κ DNA predigested with the enzymes listed above. From a comparison of this restriction map with the R-loop map previously constructed for J segments we concluded that the J DNA cluster is on the 1.7-kilobase *Hin*dIII–*Xba*I fragment (Fig. 1*a*,*b*). We then determined the entire nucleotide sequence of this fragment using a strategy shown in Fig. 1*c*.

Complete nucleotide sequence of the J-rich 1.7-kilobase *Hin*dIII–*Xba*I fragment

Figure 2 shows the complete nucleotide sequence of the *Hin*dIII–*Xba*I fragment. To date, about 30 mouse κ chains of BALB/c and NZB strains have been sequenced around the J region[10,11]. If one assumes that the Jκ region begins with residue 96 and ends with residue 108 (see below) based on the analogy to the Jλ region[4], the 30 Jκ regions fall into 10 different classes (Table 1). We therefore scanned the nucleotide sequence determined for each of the 10 predicted J sequences, and identified four (J1, J2, J4 and J5). Taking advantage of the fact that all known J regions are extensively homologous, we looked for additional J or J-like sequences and found one (J3) for which no sequenced κ chain is known. A systematic computer search for other J-like sequences that are related to the known or predicted J sequences by more than 50% homology revealed no more than the five Js in the 1.7-kilobase *Hin*dIII–*Xba*I fragment.

The amino acid sequences of the MOPC21 and MOPC321 κ chain J regions correspond to the predicted sequences of J2 and J4, respectively. Positions of these Js as determined by sequencing agree well with the positions of Js identified by R-loop mapping using the respective κ mRNA. We therefore conclude that J2 and J4 encode MOPC21 and MOPC321 J regions, respectively. Amino acid sequences of the MOPC141 and LPC1 (or HOPC8) J regions are unknown, but based on the R-loop map (Fig. 1*a*) we predict that these J regions are encoded in J1 and J5, respectively.

The distance between adjacent Js is quite constant. The five Js are arranged as follows: J1-310 base pairs-J2-246 base pairs-J3-268 base pairs-J4-299 base pairs-J5. We have recently completed sequencing a stretch of about 1 kilobase on each side of the *Hin*dIII–*Xba*I fragment and have found no J or J-like sequences. If all Js are clustered and regularly arranged every 300 or so base pairs, there should be no J sequences other than those identified here. On the other hand, if all J peptides (see Table 1) are germ-line encoded, there should be additional J DNA segments elsewhere. Alternatively, some J peptides may be somatically generated (see below).

Precise boundaries of J DNA segments

Our previous nucleotide sequencing studies of embryonic Vλ, embryonic Cλ and myeloma Vλ + Cλ DNA clones identified the site of V–J recombination within one of two alternative pairs of phosphodiester bonds[4]. To obtain similar information for a κ chain gene, it is necessary to identify a germ-line V DNA of a specific κ chain for which the J DNA sequence is known, and determine the nucleotide sequences of both germ-line V DNA and myeloma (V + C) DNA. To this end the germ-line V gene of MOPC321 κ chain, Vκ21-C, was cloned and sequenced (details to be published elsewhere). We also determined the partial nucleotide sequence of the cDNA clone of MOPC321 κ mRNA, 5D10 (ref. 3). Nucleotide sequences around the putative recombination sites on Vκ21-C and J4 (which encodes the Jκ peptide of MOPC321 κ chain, see above) as well as the sequence of the corresponding region of 5D10 are:

```
                    95
                    AsnGlnAspProPheThrPheGly
5D10                AATGAGGATCCATTCACGTTCGGC

Vκ21-C              AATGAGGATCCTCCCACAGTGGCT

J4                  GAATCACTGTGATTCACGTTCGGC
```

Examination of these sequences enabled us to conclude that the recombination is at the phosphodiester bond linking the second and third nucleotides of the proline codon at residue 95. This corresponds to residue 97 in the λ chain numbering system. In the case of one λ gene we have shown that recombination occurs either between the His(97) and Phe(98) codons or between the

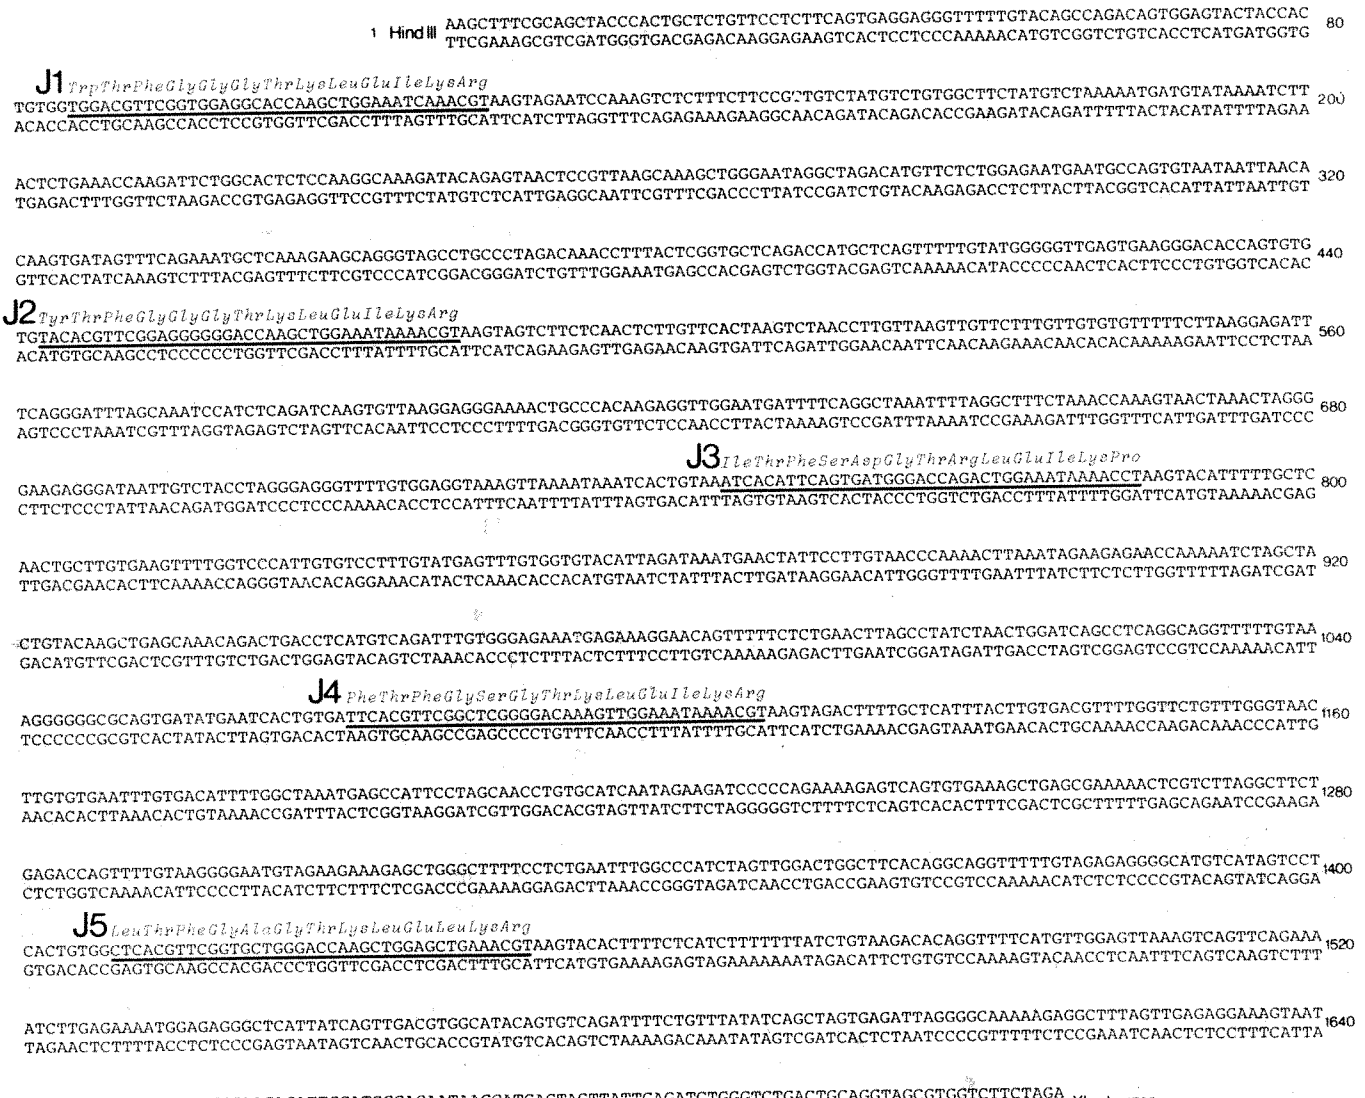

Fig. 2 Complete nucleotide sequence of the 1.7-kilobase *Hin*dIII–*Xba*I fragment containing the J cluster. For sequencing, a 2.7-kilobase *Hin*dIII–*Hin*dIII fragment carrying the J cluster (Fig. 1*b*) was subcloned into a plasmid vector pBR322 (ref. 32). A 300-μg portion of the chimaeric plasmid DNA was digested with a mixture of *Hin*dIII and *Xba*I and separated in a 6% polyacrylamide gel (20 × 40 × 0.5 cm); the 1.7-kilobase *Hin*dIII–*Xba*I fragment (Fig. 1*b*) was then purified. A 5-μg aliquot of this fragment was digested with *Hin*fI, *Mbo*II, *Alu*I, *Ava*I, *Hph*I, *Hae*III or *Ava*II, end-labelled and sequenced by the method of Maxam and Gilbert[33] as described previously[26]. In some experiments, 3′-ends of the DNA fragments were labelled with [α-^{32}P]nucleoside triphosphates (NTPs) using the Klenow fragment of *Escherichia coli* DNA polymerase I (ref. 34). For this, 1 μg of DNA was incubated with 20 μCi each of four [α-^{32}P]-NTPs (3,000 Ci mmol^{-1}, NEN) and 1 unit of the Klenow enzyme (Boehringer, Mannheim) at 25 °C for 20 min in 50 μl of 6 mM Tris-HCl, *p*H 7.5, 50 mM NaCl, 6 mM $MgCl_2$ and 6 mM β-mercaptoethanol. Aliquots (50 mM) of each of the four NTPs and 0.5 unit of the enzyme were then added to the reaction mix and the incubation was continued for another 10 min. The reaction was terminated by heating the mixture at 70 °C for 10 min and DNA was precipitated by ethanol. For strand separation the labelled DNA samples were dissolved in 20 μl of 50% (v/v) dimethyl sulphoxide, 10 mM Tris-borate, *p*H 8.3, 1 mM EDTA, 0.5% (v/v) xylene cyanol and 0.05% (v/v) bromphenol blue, heated at 90 °C for 3 min, chilled on ice and fractionated in a 6% or 8% strand-separation gel (bisacrylamide/acrylamide = 1/62.5) (A. Maxam, personal communication). Amino acid sequences predicted from the identified J DNA segments are shown in italics.

first and second bases of the latter codon[4]. Thus, the exact sites of recombination in the two cases seem to differ by one or two bases. It remains to be seen whether this difference is due to characteristics of the two recombination systems, one for κ chains and the other for λ chains. An alternative possibility is that the recombinases allow a limited flexibility in the sites of breakage and reunion regardless of the chain type (see below). In this respect it is relevant that all mouse κ chains sequenced to date carry proline at residue 95. As none of the Js reported here can code for this proline (Fig. 2) it is very likely that the first residue fully encoded in J is always at position 96. However, precise recombination sites can only be defined by comparative sequencing analysis of the three DNA segments involved.

Where does coding by J end? The sequences of J4 and 5D10 in the relevant regions are as follows:

```
                    108
                    LeuGluIleLysArgAlaAspAla
5D10                TTGGAAATAAAACGGGCTGATGCT
J4                  TTGGAAATAAAAC|GTAAGTAGACT
```

These sequences indicate that J4 can code for MOPC321 κ chain up to the second base of the Arg(108) codon, CGG. However, as J is followed by an intron preceding the C DNA segment and as most introns start with GT (ref. 12), we suggest that coding by J actually ends with the first base of the triplet CGT, as indicated by the vertical line. As shown in Fig. 3, sequences around the splice site are highly conserved among the five Js. In all cases except for J3, for which no κ chains are

Table 1 Classification of BALB/c and NZB myeloma κ chains

Group	Myeloma					Jκ Peptide (96 → 108)												Jκ DNA Segment

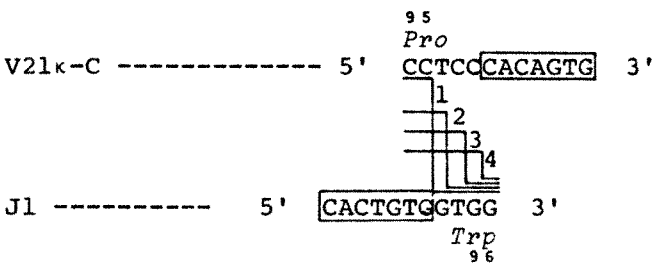
BALB/c and NZB myeloma κ chains are classified into 10 groups according to the amino acid sequence of the Jκ peptide (residues 96–108)[10,11]. The DNA segments coding for four Jκ peptides, J1, J2, J4 and J5, have been identified on the embryonic Cκ clone, Ig146κ, in the present study. No myeloma κ chain is known for the fifth J DNA segment, J3, also identified in the present study. Those amino acid residues different from the corresponding residues of the J1 peptide are underlined.

* Myelomas classified by R-loop mapping rather than by amino acid sequencing (see text).



known, the doublet GT is present in the last J triplet (CGT) that can partially encode κ chains. It is likely, therefore, that coding by J always ends with the first base of this triplet. In the equivalent position of J3 a Pro codon, CCT, replaces the Arg codon, CGT. It is not clear whether J3 is a genuine J, and if so, where the coding precisely ends.

Inverted repeat-stem structure could be formed between embryonic V and J sequences

Figure 3 compares the sequences of five Js in the coding and flanking regions. Sequences are highly conserved in the coding regions and around the RNA splice sites. In contrast, sequences in the rest of the flanking regions are rather diverse, although the non-coding sequences between J3 and J4, and J4 and J5 are somewhat similar. Nevertheless, there are two short conserved sequences in the 5′-non-coding regions. One is a decamer, GGTTTTTGTA, located about 30 base pairs away from all Js, and the other is a palindromic hexamer interrupted by an AT base pair at the centre of symmetry, CACTGTG, immediately preceding the Js. The same or closely related sequences are also present at the equivalent position in the λI chain gene clone[4].

The significance of these conserved sequences with respect to V–J joining became apparent when the sequences of an embryonic Vκ gene clone, IgVκ21-C, and an embryonic VκI clone, Ig99λ (ref. 4), were examined. Both V DNA clones contain sequences closely related to the decamer and heptamer described above on the anti-sense strands in the 3′-non-coding regions. The presence of these sequences could permit the formation of an inverted repeat stem structure between the 3′-end of an embryonic V sequence and the 5′-end of a J sequence. Examples of such stem structures are shown in Fig. 4*a–d*. Vκ21-C can form a stem structure of similar stability with any one of the five Js. Another Vκ gene, VK-2 (ref. 13), which codes for a V region remotely related to the MOPC321 V region, can also form such a stem structure with any one of the five Jκs (Fig. 4*c*). We note that the majority of bases conserved in the 3′-non-coding regions of the two Vκ genes participate in base pairing with Jκs. A stem structure can also be constructed between embryonic Vλ and embryonic Jλ, although the homology is lower than that of the Vκ–Jκ stems (Fig. 4*d*). We propose that the hybrid stem structures are part of the recognition signals for the putative site-specific recombinase.

In all cases known, a few base pairs occur between either one or both cut points of recombination and the stem bases. Thus, for the V–J joining leading to the MOPC321 κ chain gene, the only case in which the exact cut points are known, three base pairs intervene between the cuts on V21κ-C and the stem bases, whereas the cuts on J4 are actually at the bases (Fig. 4*a*). We do not know whether this relationship between the cut points and the stem bases applies to other recombination events between various pairs of Vκs and Jκs, nor whether recombination between Vκ21-C and J4 always occurs at the same sites as shown in Fig. 4*a*. As residue 96 is a hot spot[10,11], one intriguing possibility is that the recombinase can cut and rejoin the DNA strands of a given pair of V and J at slightly different positions so that different triplet codons are reconstituted at the recombination site. For example, the hypothetical recombination events between V21κ-C and J1 (Fig. 4*b*) may occur in any one of the following four ways:

where recombinations 1 and 2 give the same dipeptide Pro(95)–Trp(96), whereas recombinations 3 and 4 generate Pro(95)–Arg(96) and Pro(95)–Pro(96), respectively. The latter two recombination events can account for the group III and group IV J peptides, respectively (see Table 1). It follows that the total number of Jκ DNA segments might be considerably less than the number of different Jκ peptides.

The inverted repeat structures described above have some resemblance to those found at the ends of prokaryotic insertion elements. Ohtsubo and Ohtsubo[14], and Grindley[15] determined sequences of IS1 and found that some 30 bases at one end are invertedly repeated on the other end. Inverted repeat sequences of similar length have also been found at the ends of most insertion elements. Integration of insertion elements into host DNA generates 5- or 9-base pair direct repeats at the outer ends of the inverted repeat sequences[15–22,36]. The conserved palindromic sequences, CACAGTG near V genes and CACTGTG near Js, can be considered to be equivalent to these direct repeats observed at the margins of integrated insertion elements. Although these structural similarities may be coincidental, they could reflect a common evolutionary origin or a common enzymatic mechanism for the two recombination systems, or both.

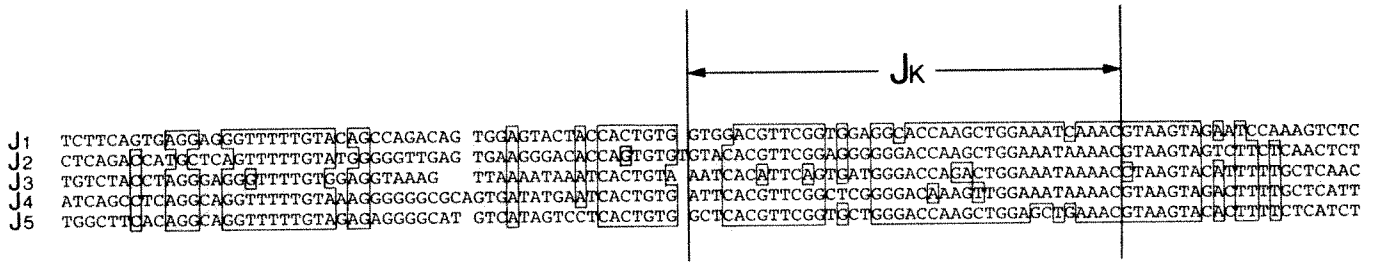


Fig. 3 Comparison of nucleotide sequences of the five J-coding and the flanking regions. Nucleotides common in at least four Js are outlined. Vertical lines indicate determined or predicted ends of the J-coding DNA segments.

V–J joining probably results in deletion

Several models have previously been proposed for recombination of immunoglobulin genes[2]. In the 'copy–insertion' model, a specific V DNA segment is duplicated and the copy is inserted at a site adjacent to a J DNA segment. The 'excision–insertion' model suggests that a specific V DNA segment is excised into an episome-like structure, and this in turn is integrated adjacent to a J DNA segment. According to the 'deletion model' the entire DNA in the interval between a particular pair of V and J DNA segments loops out, is excised, and is diluted out on subsequent cell multiplication. In the 'inversion' model the V and the C DNA (also J DNA) segments are arranged in opposite directions, and a segment of chromosome between a particular V DNA (inclusive) and a J DNA (exclusive) is inverted.

In the context of these models, let us consider the fate of the DNA sequences immediately adjacent to the 3′-end of V, or immediately adjacent to the 5′-end of J. In all the models except for the deletion model, either one of the two sequences or both should recombine with DNA sequences elsewhere in the genome on V–J joining. In contrast, the deletion model predicts that both sequences should be eliminated. To test these two alternatives, we investigated the λI chain gene in which both V and J are unique. We digested embryo and myeloma (H2020) DNA with various restriction enzymes, fractionated the digests in a 0.8% agarose gel, and analysed the DNA by Southern gel-blotting procedures. As the hybridisation probes we used a DNA fragment of about 300 base pairs from an embryonic VλI clone, Ig99λ, or from an embryonic CλI clone, Ig25λ, that includes the respective recombination site as shown in Fig. 5*E*. Both DNA fragments contain not only the sequence to be examined (*b* or *c*) but also an adjacent sequence (*a* or *d*) known to be incorporated into the rearranged λ chain gene. We deliberately chose such DNA fragments as hybridisation probes to let the *a* and *d* part serve as internal hybridisation controls.

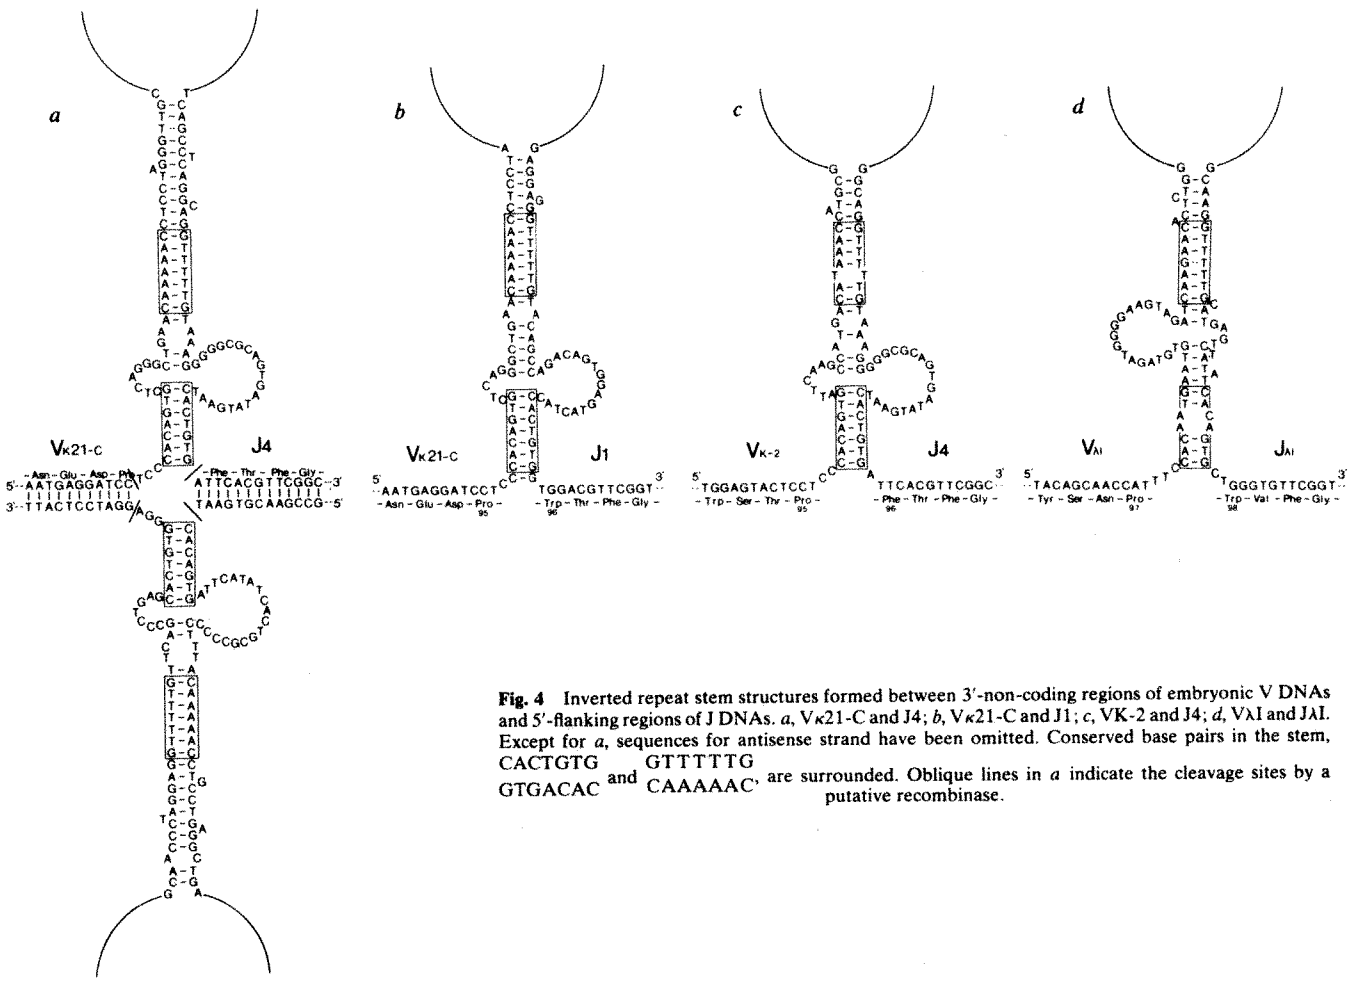

Fig. 4 Inverted repeat stem structures formed between 3′-non-coding regions of embryonic V DNAs and 5′-flanking regions of J DNAs. *a*, Vκ21-C and J4; *b*, Vκ21-C and J1; *c*, VK-2 and J4; *d*, VλI and JλI. Except for *a*, sequences for antisense strand have been omitted. Conserved base pairs in the stem, CACTGTG GTTTTTG / GTGACAC and CAAAAAC, are surrounded. Oblique lines in *a* indicate the cleavage sites by a putative recombinase.

Figure 5*A* compares hybridisation patterns of embryo and myeloma DNA that were digested with *Eco*RI and analysed with the *ab* probe. Embryo DNA gave two bands of 4.8 and 3.5 kilobases that had previously been identified as VλII- and VλI-containing fragments, respectively[3-5]. In the myeloma DNA an additional band of 7.4 kilobases known to contain the rearranged, complete λI gene[4] was observed, but no previously unidentified band was present, which would have been expected if the DNA sequence corresponding to the *b* part of the probe had recombined with another DNA sequence. Results of analogous experiments obtained with the *cd* probe are shown in Fig. 5*C*. Embryo DNA gave a band of 8.6 kilobases known to contain the CλI sequence, and another band, X. The latter band contained a sequence homologous to JλI and its flanking regions (unpublished observations). Myeloma DNA gave these two bands and an additional band of 7.4 kilobases containing the rearranged λI chain gene[3]. Again, we observed no myeloma-specific band that could be attributed to the hypothetically recombined DNA containing the *c* part of the prqbe. Similar results obtained with *Hin*dIII are shown in Fig. 5*B* and *D*. We did not observe myeloma-specific DNA fragments that could not be accounted for by the rearranged, complete λI chain gene with either probe. We have carried out similar experiments using *Kpn*I, *Bam*HI, *Hin*dII and *Hae*III, and obtained results that lead us to the same conclusion (data not shown). Although the results do not unequivocally prove the deletion model (more complicated models in which elements of the other models are combined cannot be ruled out), they suggest strongly that it is the correct one.

Evolution of light-chain genes

We thus suggest that V–J joining is a recombination event accompanied by excision of the DNA sequence between the V and J DNA segments. This DNA sequence, which we call *excison*, carries at its ends characteristic inverted repeat sequences consisting of about 30 bases that could form a stem-loop structure somewhat similar to those of prokaryotic insertion elements. In the light of these findings and the intron–exon structure of immunoglobulin genes we will consider some aspects of the evolution of light-chain genes.

The V and C regions of light chains show a weak sequence homology and are similar in their size, in arrangement of intra-chain disulphide bonds and in three-dimensional structure[23-25]. Based on these observations it has been generally thought that the DNA segments coding for the two regions arose by duplication of a primordial gene coding for a single homology unit (Fig. 6, step *a*). As we discussed elsewhere this duplication step probably generated a 'dimeric gene' in which the ancestral V- and C-coding DNA segments are separated by a spacer[26]. When this gene is expressed, the entire DNA is transcribed into a single RNA molecule and the spacer sequence is presumed to have been removed by splicing of the V- and C-coding RNA sequences. We assume that the J DNA segment was an integral part of the ancient V DNA because the J region is homologous to the carboxyl end of the C region[35].

The ancestral V DNA, together with some flanking sequences, duplicated, triplicated, and so on under pressure to increase V-region diversity (Fig. 6, step *b*). As splicing is most probably an intramolecular reaction, one requirement of such a 'polymeric gene' would be that the V and C DNA sequences are co-transcribed. In the long RNA transcript every V-coding sequence would have one half-pair of RNA splice sites at its 3′-end (the other half-pair is at the 5′-end of the C-coding sequence), so that a series of mature mRNAs containing different V-coding sequence and the same C-coding sequence could be generated. However, the V–C co-transcription requirement would impose a limit on the size of such a polymeric gene because the transcription unit would become intolerably long as the gene grows. To accommodate 200 V-coding DNA segments, a number estimated for mouse κ chains[2,8,13,27,28], the transcript would have to be 100 kilobases long even if no spacer

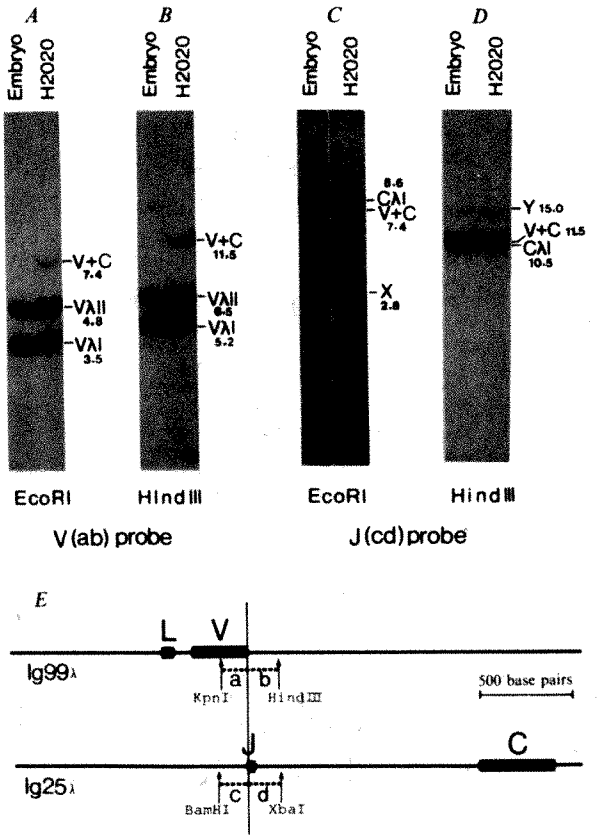

Fig. 5 Southern gel blots of total cellular DNA assayed with hybridisation probes containing the sequences around the recombination sites. High molecular weight DNA extracted from 13-d-old mouse (BALB/c) embryo or from λI light-chain-producing myeloma, H2020, was digested with *Eco*RI (*A* and *C*) or *Hin*dIII (*B* and *D*). The DNA fragments were separated in a 0.8% agarose gel and transferred to a nitrocellulose filter (Schleicher–Schuell, BA85). Filters were then incubated as previously described[3] in the presence of 2×10^7 c.p.m. of one of the two nick-translated DNA probes, $a+b$ and $c+d$, whose sequence compositions are indicated in *E*. *A* and *B*, hybridisation with the $a+b$ probe composed of the 330-base pair *Kpn*I–*Hin*dIII fragment purified from an embryonic VλI gene clone, Ig99λ. *C* and *D*, hybridisation with the $c+d$ probe composed of the 294-base pair *Bam*HI–*Xba*I fragment purified from an embryonic CλI gene clone, Ig25λ. Among the bands detected, those indicated to contain λ-coding sequences have previously been characterised by the analysis of DNA clones containing the corresponding DNA fragments. Band X was also cloned, and analysed by electron microscopy of heteroduplexes formed between the cloned DNA and the Ig25λ DNA. It contains a sequence homologous to JλI and its flanking region (unpublished observation). Band Y has not yet been characterised. Note that both band X and band Y are present not only in the myeloma DNA but also in the embryo DNA. Molecular sizes are indicated in kilobase pairs.

between two adjacent V DNA segments is postulated. The hypothetical transcript may be much larger because at least one such spacer seems to be 10 times longer than a V DNA segment[9]. One obvious solution is to duplicate the entire polymeric gene of a still allowable size. Indeed, all mammals studied so far seem to carry several unlinked sets of light-chain V DNA clusters each associated with a C-coding DNA segment.

An alternative solution is to rearrange DNA sequences somatically so that the V DNA to be expressed is brought in the vicinity of the C DNA in the lymphocytes. We propose that such a mechanism was initiated when an IS-like DNA element was accidentally inserted into one of the multiple V DNA copies of an ancestral polymeric gene, splitting it into two portions, one corresponding to the present day embryonic V DNA segment and the other to the J DNA segment (Fig. 6, step *c*). While this insertion was fixed in the germ-line genome, a mechanism to excise the inserted DNA and rejoin the split V-coding sequences was established in lymphocytes. As excision is a common and major manifestation of prokaryotic IS elements, the basic mechanism for such a process would probably have been

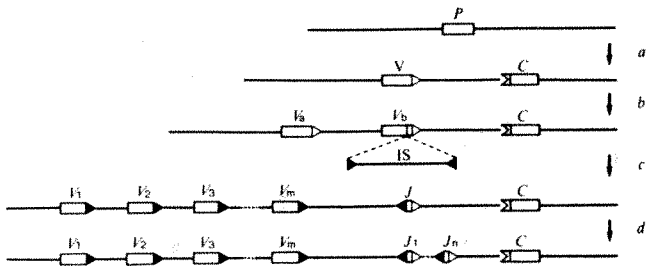

Fig. 6 A hypothetical scheme for the evolution of the κ-light-chain genes. *P*: a primordial gene coding for a single homology unit of immunoglobulin chains. *V*: an ancient variable-region gene. *C*: a constant-region gene. IS: a DNA element thought to be inserted into one of the *V* copies, splitting it to a 5′-portion, *V*, and a 3′-portion, *J*. ▷ and ▷◁ designate a pair of splice sites. ► and ◄ designate inverted repeat sequences at the ends of IS. Step *a*, duplication of *P* and generation of a pair of splice sites at or near the inward ends of *V* and *C*. Step *b*, limited multiplication of *V* and accidental insertion of IS into one of the multiplied *V*s, *V*b. Step *c*, multiplication of *V* and one half-pair of the inverted repeat sequences. Step *d*, multiplication of *J* and the other half-pair of the inverted repeat sequences. See text for details.

available in vertebrates. Once an ancestral V DNA is split, the major body of the V-coding sequence and the flanking sequences containing one of the two invertedly repeated sequences can multiply independently of the J DNA (Fig. 6, step *c*). Because every copy of the duplicated V DNA would have the excision–recombination site at its 3′-end, it can rejoin with the J DNA which is kept in the vicinity of the C DNA. Because the rearranged V DNA can bring in its own promoter, it is no longer necessary to confine the duplicated V DNA copies and the C DNA within the same transcription unit in the germ-line genome.

Multiplication of J DNA segments is an additional aspect of the evolution of light-chain genes (Fig. 6, step *d*). Amino acid sequencing studies of mouse κ chains suggest that a single J DNA segment can recombine with more than one V DNA segment in different lymphocyte clones. Conversely, a single V DNA segment seems to be capable of recombining with more than one J DNA segment[10,11]. In addition, a single J DNA segment can give rise to multiple J peptides by a slight shift of the recombination site between a given pair of V and J. Although the pressure under which J DNA segments multiplied is unknown, diversification of V regions may have been the primary source. As residue 96, the first amino acid fully encoded in J, is one of the third complementarity-determining residues[29], the J peptide could contribute to the antigen-binding activity of the antibody.

Thus, the V–J joining may well be a reversal of an ancient accidental insertion of an IS-like DNA element which was subsequently exploited by vertebrates to increase the V-region diversity within the general framework of the intron–exon structure of higher cell genes.

We thank D. J. McKean and M. Potter for unpublished results, Y. Shimura for restriction enzyme *Ava*II, T. Friedmann for advice on the 3′-end labelling of restriction fragments, T. Knaak for the computer program, G. Dastoornikoo and André Traunecker for technical assistance, and T. Bickle, M. Julius and R. Maki for reading the manuscript.

Statistical mechanics of supercoils and the torsional stiffness of the DNA double helix

A. V. Vologodskii, V. V. Anshelevich, A. V. Lukashin & M. D. Frank-Kamenetskii

Institute of Molecular Genetics, Academy of Sciences of the USSR, Moscow 123182, USSR

The distribution of closed unknotted polymer chains over the writhing number is calculated by the Monte-Carlo method. For circular duplex DNA the variance of the distribution equals approximately half the observed variance of equilibrium distribution over the linking number. The balance which arises from fluctuations in DNA twisting makes it possible to estimate the torsional stiffness of the double helix.

MANY intriguing questions such as the spatial structure of superhelical DNA and the packaging of DNA inside virus particles and chromosomes, are often discussed in terms of the conformational flexibility of the double helix. In most cases changes in the DNA tertiary structure are thought to stem from small continuous local deformations of the double helix[1–7]. Within the framework of this model, DNA can be thought of as an elastic rod with properties completely characterised by its bending and torsional stiffnesses[8]. The resistance of DNA to the bending of the axis of the double helix is deduced from the experimentally determined DNA persistence length using the Bresler and Frenkel theory[9] (see also refs 10, 11).

Although in the past there has been an ambiguity in the value of the DNA persistence length, recent precise measurements using new techniques have provided a reliable estimate of about 600 Å in standard ionic conditions (0.2 M Na^+)[12–16]. This has made it possible to calculate the energy associated with the bending of the helix axis in DNA packaging within viruses[5], nucleosomes[6] and in the formation of the DNA superhelix[7].

The value of the torsional stiffness of the double helix, however, remains obscure. This is partly because the torsional stiffness does not affect any properties of linear DNA molecules. On the other hand, all properties of closed duplex DNA should depend in one way or another on the torsional stiffness of the double helix. But in most cases experimentally observed characteristics depend only indirectly on torsional stiffness, and recent attempts to evaluate the torsional stiffness have led to contradictory results[17,18].

In this article we demonstrate that the experimental data of Depew and Wang[19] and Pulleyblank *et al.*[20] offer a reliable estimation of the DNA torsional stiffness. These authors measured the equilibrium distribution of closed duplex DNA molecules over the number of titratable superhelical turns after enzymatic conversion of open circular (nicked) molecules into the closed form. Although this experimental distribution is determined by thermal fluctuations both in the torsional winding of the double helix and in the number of its tertiary turns[19,21], the latter may be theoretically calculated provided that the bending stiffness is known. The balance makes it possible to estimate the torsional stiffness of the double helix.

Rigorous formulation of the problem

Our treatment is based on the important results obtained in the field of differential topology during the last 20 years[22–25]. Fuller[26] was the first to emphasise the crucial significance of these findings for an analysis of closed duplex DNA and overtly introduced the important notion of the writhing number (Wr). This was defined as the difference between the topological characteristic of closed duplex DNA, the linking number (Lk) of the two complementary strands, and the total twist (Tw) of the strands measured along the helix axis.

The concepts of Lk, Tw and Wr are explained at length by Fuller[26,27] and Crick[28]. The central point is that the writhing number depends only on the spatial arrangement of the helix axis. Roughly speaking, this concept corresponds to our intuitive notion of the number of tertiary turns. However, even in the simplest case of a regular superhelix, the writhing number does not equal the number of superhelical turns[26–28].

In terms of the values of Lk, Tw and Wr, the problem of quantitative interpretation of the experimental results on equilibrium closing of nicked DNA[19,20] may be formulated as follows[21]. In nicked DNA the deviation ΔTw in twisting from the mean value and changes in the writhing number occur due to thermal motion. The experimentally determined value of ΔLk is expressed through these fluctuating characteristics:

$$\Delta Lk = \Delta Tw + Wr \qquad (1)$$

It is obvious that the averaged values $\langle Wr\rangle = \langle \Delta Tw\rangle = \langle \Delta Lk\rangle = 0$. However, the values of $\langle(\Delta Tw)^2\rangle$ and $\langle(Wr)^2\rangle$ should be nonzero and because in a nicked molecule the fluctuations in twisting and in the number of tertiary turns occur independently from each other[19,21]:

$$\langle(\Delta Lk)^2\rangle = \langle(\Delta Tw)^2\rangle + \langle(Wr)^2\rangle \qquad (2)$$

The value of $\langle(\Delta Lk)^2\rangle$ was determined experimentally[19,20,29]. On the other hand, the value of $\langle(Wr)^2\rangle$ is fully determined by the bending stiffness of the helix axis. So, if it were theoretically calculated using the known value of the DNA bending stiffness, the value of $\langle(\Delta Tw)^2\rangle$ would remain the only unknown quantity in equation (2). The value of $\langle(\Delta Tw)^2\rangle$ is connected with the value of the torsional stiffness in a simple way.

So, to determine the DNA torsional stiffness from the experimental data[19,20,29], one should calculate the $\langle(Wr)^2\rangle$ value. To this end we used the Monte-Carlo method. To obtain a reliable estimate of the desired value the calculation scheme should meet the following requirements: (1) An algorithm should make it possible to generate closed chains in space with a correct probability distribution. (2) A strict algorithm should make it possible to calculate the writhing number for an arbitrary spatial curve. (3) Since the experiments[19,20,29] were performed with molecules extracted from cells and virus particles in the closed duplex form, the samples most probably contained only unknotted molecules (in a general case the process of replication of a knotted DNA molecule should meet with obstacles[30]). However, when one randomly generates a closed chain it may prove to be knotted with some definite probability[30]. To discard such knotted chains in the course of the Monte-Carlo calculations a reliable computer algorithm is needed to recognise them. (4) Since the Monte-Carlo calculations are performed for some simplified models of the real DNA molecule, one should prove that the results are still valid when one passes to more realistic models.

Note that Benham[21] who recently attempted to solve the same problem used a calculation scheme that satisfied none of the above requirements. In contrast, the calculation scheme outlined below meets all the above requirements and makes it possible to obtain, for the first time, a reliable estimation of the $\langle(Wr)^2\rangle$ value.

The calculation scheme

To calculate the writhing number for a closed curve in space simulating the position of the central axis of a DNA molecule we have used two independent but equally rigorous approaches.

The first one is as follows[26]. A curve is projected onto a plane perpendicular to an arbitrary direction. For this projection the so-called directional writhing number[21,26] is calculated. The writhing number Wr is the average of the directional writhing

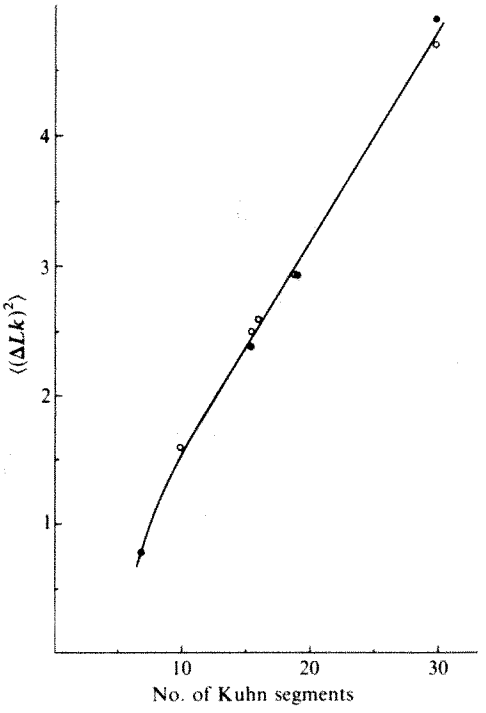

Fig. 1 Experimental dependence of the variance of equilibrium distribution over the linking number Lk on the number of Kuhn statistical segments in DNA molecules. The points correspond to the following DNAs (the values in parentheses are the numbers of base pairs): plasmid 15 of *E. coli* (2,300); minicol (3,300); SV40 (5,224); polyoma (5,380); Col E1 (6,360); fd (6,408); PM2 (10,050). The $\langle(\Delta Lk)^2\rangle$ values were taken from refs 20, 29 (○) and ref. 19 (●). The Kuhn statistical length was chosen to be equal to 1,150 Å (338 base pairs)[16].

number over all directions. A practical limitation of this method is that to obtain a reliable Wr value one has to analyse a great number of projections of a curve in different directions, so this is too time-consuming for routine Monte-Carlo calculations.

Another method based on a representation of the writhing number in terms of the gaussian integral is more convenient. It follows from the definition of the Wr value[26] and from the results in refs 22–25 that

$$Wr = \frac{1}{4\pi} \int\int \frac{(d\mathbf{r}_1 \times d\mathbf{r}_2)\mathbf{r}_{12}}{r_{12}^3} \qquad (3)$$

where $\mathbf{r}_1$ and $\mathbf{r}_2$ are the radius vectors whose ends run along the curve and $\mathbf{r}_{12} = \mathbf{r}_1 - \mathbf{r}_2$. Although in routine calculations we used the second method based on equation (3), our main results were also verified by the first method. Note that when the first method is used in Monte-Carlo calculations it is essential that the directional writhing number for each generated curve be averaged over its different projections before averaging the value $(Wr)^2$ over the different curves. Otherwise $\langle (Wr)^2 \rangle$ values are overestimated (this is one of Benham's[21] faults). A great advantage of the use of equation (3) in the Monte-Carlo calculations is that in these calculations the curves always consist of straight segments. We therefore represented the double integral in equation (3) for a total curve as the double sum over these segments and used an analytical expression for the value of the integral for a pair of straight segments.

To see if a randomly generated closed curve is knotted, we have calculated the topological invariant of knot (Alexander polinomial) as we did previously in our study on statistical mechanics of knots[30,31].

The Monte-Carlo calculations can be performed only for some simplified polymer models. These calculations are simplest for a model of freely joined straight segments, but actual DNA is most probably a continuous worm-like structure. It is known, however, that various mean characteristics of a polymer chain depend on the number of Kuhn statistical segments alone, and are independent of the particular polymer model, if the number of Kuhn segments is not too small. Special calculations show that this is also true for $\langle (Wr)^2 \rangle$. Indeed, the results hold as one passes from the free-joint model to a model with a free rotation of adjacent segments within a cone determined by a fixed angle between the segments. We compared the results obtained on the two models for the same number of Kuhn statistical segments. So we believe that our results should be valid for the worm-like model which is a limit of the model with free rotation.

We did not take into consideration the excluded volume effects because they are known to be negligible in ordinary conditions for the DNA chain lengths involved.

Finally, note that there is a very effective algorithm for the model of a freely joined chain (A. M. Dykhne, unpublished), making it possible to generate only closed chains in space. There is no such algorithm for the free-rotation model. To check the validity of our results for the free-rotation model we repeated some of the calculations using a very cumbersome method involving straightforward generation of arbitrary chains of a given length with a subsequent selection of those having a small enough distance between the ends.

Results

Figure 1 shows all the published experimental data on the variance of equilibrium distribution over the linking number $\langle (\Delta Lk)^2 \rangle$ as a function of DNA chain length. Chain length is expressed in terms of the number of Kuhn statistical segments, using the Kuhn statistical length of 1,150 Å given by Kovacic and van Holde[16]. Note that other recent estimations of this quantity[12–15] differ insignificantly from the chosen value (the Kuhn statistical length is double the persistence length). In the original papers[19,20] it was proved that the experimentally measured distribution over the linking number was in fact an equilibrium distribution. Note the high accuracy of the experimental data, as demonstrated by the very good agreement between results obtained in two different laboratories with several different DNA preparations and with two different enzyme systems (DNA ligase and a nicking-closing enzyme).

Figure 2 shows the results of our calculations of the variance of distribution over the writhing number $\langle (Wr)^2 \rangle$ as a function of the number of Kuhn segments in a closed polymer chain. The dotted line shows the results obtained when the $\langle (Wr)^2 \rangle$ value was calculated for all randomly generated closed chains both unknotted and knotted. The solid line corresponds to the results obtained for unknotted chains only. As mentioned above, it is probable that only the latter results correspond to the experimental situation. Note that although for the number of segments under study the percentage of knotted chains is very small (not more than about 5%, see refs 30, 31) they contribute appreciably to the $\langle (Wr)^2 \rangle$ value. Thus analysis of randomly generated chains on their topological state proved to be absolutely essential (see also below).

Figures 1 and 2 show that the calculated value of $\langle (Wr)^2 \rangle$ is almost equal to half the experimental $\langle (\Delta Lk)^2 \rangle$ value. Our data sharply contradict the data of Benham[21] who calculated a value for $\langle (Wr)^2 \rangle$ which was about four times larger than ours. In this connection it should be stressed that our calculations meet all the above-listed requirements and their statistical error is negligible. Our results can therefore be used for obtaining, from the experimental data summarised in Fig. 1, a reliable estimation of the variance of the twisting of DNA strands about the central axis $\langle (\Delta Tw)^2 \rangle$ which, according to equation (2), is simply the difference $\langle (\Delta Lk)^2 \rangle - \langle (Wr)^2 \rangle$. Figure 3 shows the results.

The result presented in Fig. 3 was obtained for a particular Kuhn statistical length (1,150 Å). The accuracy of the latter may be estimated at about 10% (see refs 12–16). It means that the possible error in the $\langle (\Delta Tw)^2 \rangle$ value estimation is about 20%.

The ΔLk value has a gaussian distribution[19,20,29]. Our calculations show that the same is true of the Wr value. It follows from these data and equation (1) that the ΔTw value should be normally distributed.

Let us now interpret the obtained value of $\langle (\Delta Tw)^2 \rangle$ in terms of the DNA torsional stiffness. We shall only consider the simplest model of independent variations of adjacent angles between nucleotide pairs. If a DNA molecule consists of $N+1$ base pairs it has N such independent angles. For each of them

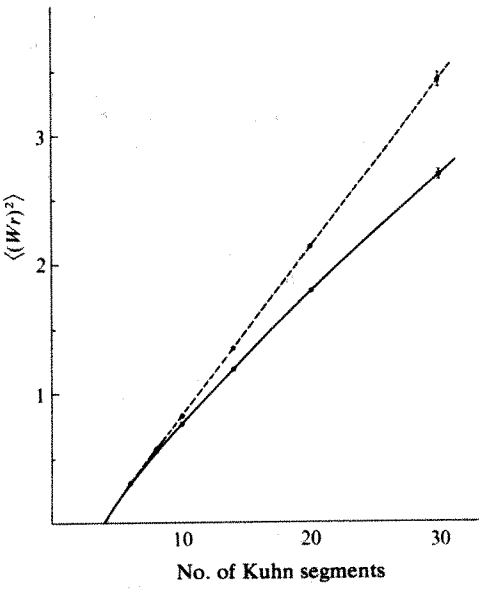

Fig. 2 Results of calculations of the variance of distribution over the writhing number Wr for a closed polymer chain as a function of the number of Kuhn statistical segments in it. The solid line refers to the case of unknotted chains only. The dotted line corresponds to the case when all randomly generated closed chains, both unknotted and knotted, are taken into consideration. The error bar is shown for the case of 30 segments. In all other cases the statistical error of the Monte-Carlo calculations is negligible.

one can use a parabolic dependence of the energy f on the deviation $\Delta\tau$ of the angle from its equilibrium position:

$$f = \tfrac{1}{2}g(\Delta\tau)^2 \quad (4)$$

where g is the value of torsional stiffness.

The probability of a given value of $\Delta\tau$ should conform to the Boltzmann equation

$$P(\Delta\tau) \sim \exp\left(-\frac{f}{RT}\right) = \exp\left(-\frac{g(\Delta\tau)^2}{2RT}\right) \quad (5)$$

As a result the variation in the total twisting angle of the molecule expressed in terms of the number of revolutions will have a gaussian distribution with the variance

$$\langle(\Delta Tw)^2\rangle = N\frac{RT}{g} \quad (6)$$

So, the value of $\langle(\Delta Tw)^2\rangle$ should be directly proportional to N and the slope of the straight line determines the value of torsional stiffness g. In accordance with equation (6) the calculated value of $\langle(\Delta Tw)^2\rangle$ is directly proportional to N (see solid line in Fig. 3). This result is by no means trivial and is valid only for precise calculations. This is demonstrated by the dotted line in Fig. 3, which was obtained from the same experimental data as Fig. 1, but using the theoretical curve for the $\langle(Wr)^2\rangle$ value calculated without the exclusive selection of unknotted chains (the dotted line in Fig. 2).

If the $\Delta\tau$ value is measured in angular degrees, then the numerical value of torsional stiffness which follows from the application of equation (6) to the data of Fig. 3, is

$$g = 0.036\,RT \quad (7)$$

It follows from the above estimation of the accuracy of determination of the $\langle(\Delta Tw)^2\rangle$ value that the obtained g value should be accurate to within 20%.

Note that we have restricted ourselves to considering only the simplest model of DNA torsional fluctuations. In principle, the same value of $\langle(\Delta Tw)^2\rangle$ may originate, for instance, from rare but marked changes in the winding angle of the double helix. An ultimate choice between different models cannot be made on the basis of the obtained $\langle(\Delta Tw)^2\rangle$ value alone. As mentioned in the introductory section, the above model which treats DNA as an elastic rod seems today preferable to other models. Note that there is no contradiction between this model and the concept of local fluctuational opening of the double helix[32,33], because the probability of the latter process in linear or nicked DNA is too small to account for the observed bending as well as torsional flexibility.

Discussion

The above results make it possible to clear up several intriguing questions. First the data lead directly to the conclusion that half of the total number of the titratable superhelical turns in closed duplex DNA is realised as tertiary turns (writhing number) and the other half is realised as the axial twisting (or untwisting) of the double helix. Note that all experimental techniques give the number of titratable superhelical turns only (see for example ref. 34). Our results make it possible for the first time to infer the number of tertiary turns (more exactly, the writhing number) from the experimentally determined number of titratable superhelical turns which is of great importance, for example, for a quantitative interpretation of the hydrodynamic properties of superhelical DNAs. The number of titratable superhelical turns remains strictly constant under fixed external conditions in a given molecule, but this constant value may be distributed in different ways between writhing and twisting. Using the results of theoretical treatment of the problem by Le Bret[17] and our results it is clear that the distributions over the writhing number and twisting in closed duplex DNA are virtually identical and their variance amounts to half the variance in nicked DNA calculated above.

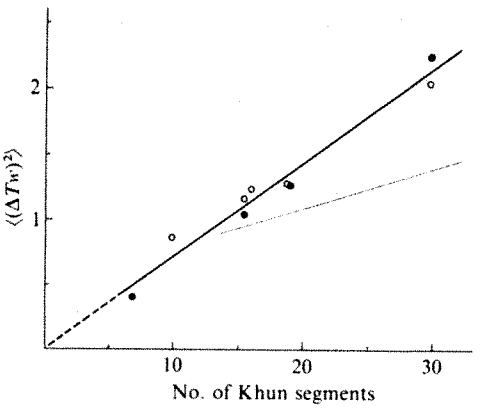

Fig. 3 The variance of the distribution over axial twisting Tw, calculated on the basis of Figs 1 and 2. Points are obtained from the experimental points in Fig. 1 and the solid line in Fig. 2 which corresponds to unknotted chains. The straight solid line is plotted through the resulting points. The dashed line is obtained from the same experimental data as for Fig. 1 but using the dotted line in Fig. 2 which was obtained without exclusive selection of unknotted chains.

For example, let us consider PM2 DNA. It has, in standard conditions, about 100 titratable superhelical turns[34]. So, the number of tertiary turns (the writhing number) for this DNA should be about 50, with the root-mean-square deviation of about unity. Note that the latter value does not contradict the fact that a sample containing the superhelical DNA molecules with a given number of topological turns gives a very sharp band in gel electrophoresis with a halfwidth much smaller than the distance between two bands which differ by one topological turn (that corresponds to only half a tertiary turn). As was emphasised by Depew and Wang[19], the width of a single band does not reflect the distribution of molecules with a given topology over different numbers of tertiary turns. So this width cannot be used for estimating the variance of the distribution as Le Bret[17] attempted to do.

Our estimation of the DNA torsional stiffness makes it possible to evaluate, for the first time, the free energy that is required to change the DNA winding angle at a given value. This free energy proved to be unexpectedly small. For instance, a change in the angle of 2.6°, which is the difference in this angle between the B and C forms of DNA, corresponds to a change in free energy of no more than 0.12 RT (72 cal mol^{-1} of base pairs).

Assuming that angles between different base pairs change independently one can estimate the amplitude (root-mean-square deviation) of thermal fluctuations in the value of the angle between adjacent base pairs that proves to be as large as ±5°. This may be directly estimated from the data in Fig. 3 without any additional assumptions (the amplitude is equal to $(\langle(\Delta Tw)^2\rangle/N)^{1/2}$). Note that, within the framework of the continuous model, this value may be overestimated only if there is a strong correlation between changes in the winding angle of sites far removed from each other. Of course, some correlation may exist but it is not very likely to be significant.

The large fluctuations in the winding angle that follow from our results most probably reflect more complex fluctuational changes in the DNA conformation. Theoretical conformational analysis suggests that the energy map of DNA has a long 'ravine' that corresponds to forms of the so-called B family[35]. It is natural to assume that the fluctuations in the winding angle correspond to a motion along the bottom of this ravine. In this case one can expect that along with the large fluctuations in the winding angle, other parameters, such as the inclination of base pairs (tilt) and the propeller of bases in the pairs should also markedly fluctuate. Presumably it is these fluctuations that lead to the considerable absorption of the light polarised along the helix axis[36]. Note that our concept does not contradict the results

of X-ray analysis of DNA fibres just because these fluctuations in fibres may be much smaller than those seen in solution due to intermolecular interaction.

Our conclusion that the large variability in DNA structural parameters can entail simple thermal motion may help clarify the mechanism of DNA–protein recognition. Indeed, these data throw great doubt on any concept that relates that recognition to small variations of DNA structure in sites with different sequences.

Weak low-latitude X-ray sources and local galactic structure

A LONG-STANDING problem of astronomy has been the elucidation of conditions that prevail in the local solar neighbourhood. Starting with Gould[1], work has continued to try to map out the morphology of the Milky Way in the vicinity of the Sun. It was noted a century ago[1] that the nearby OB stars were not distributed symmetrically with respect to the galactic plane. We report here some of the interesting contributions that X-ray sources make towards this picture.

Evidence is mounting that the low latitude ($|b^{II}| < 20°$), weak ($S < 200$ Uhuru c.p.s.) X-ray sources are situated in the solar neighbourhood. I have shown previously that the latitudinal distribution of these sources places them probably within ~ 2 kpc of the Sun, radiating between 10^{32} and 10^{34} erg s^{-1} in the 2–6 keV range[2]. This is corroborated by the discovery of stars such as Algol and γ Cas radiating in this energy band with this luminosity, as well as by models of Fabian, Pringle and Rees[3] that yield X-ray energies of this magnitude originating from accretion onto white dwarfs.

A remarkable statistic emerges when the galactic latitude of these sources ($5 < S < 50$ c.p.s.) is plotted from the 4U catalog[4]: 32 of the sources have negative galactic latitudes whereas only eight have positive values. The probability that this is a chance occurrence of a uniformly distributed population is 9×10^{-5}, calculated by

$$\sum_{i=8}^{n} \binom{n}{i} \times 0.5^n,$$

where $S = 32$ and $n = 40$. Thus, this is a statistically significant ($\approx 4\sigma$) indication of a non-random distribution of X-ray sources about the galactic plane. Furthermore, if one extends the analysis to 200 c.p.s. (where confusion will be caused by galactic centre sources), and to 4 c.p.s. (where confusion will be caused by extragalactic sources), the statistic remains $> 3\sigma$. For the inclusive population ($4 < S < 200$ c.p.s.), 50 sources have negative latitudes and 25 are positive. This is shown in Fig. 1, and summarised in Table 1. Note that the Ariel 5 satellite identified 22 new sources not in the Uhuru catalog: 15 are below the plane, and seven are above[5,6]. Unfortunately, the statistics are not adequate for a two-parameter fit to an equation of the type $b^{II} = A \sin l^{II} + B \cos l^{II}$ (see ref. 2), but a coincidence emerges when gross features are examined. For example, in the region $90° < l^{II} < 300°$, 22 sources ($4 < S < 200$) have negative galactic latitudes, and six are positive. This is close to the region where most local O and B stars are found to be below the galactic plane[7–9], and is further evidence that the weak sources reside in the solar neighbourhood. In fact, within 300 pc of the Sun, 115 O and B stars are located below the plane, and 79 are above[9], an asymmetry which is approximately 3σ. This result is subject to observational selection as it excludes parts of the southern Milky Way; thus, the asymmetry will, if anything, be enhanced.

Extending the anaology with local objects we can for the first time understand the log N log S slope of -0.4, discovered by Matilsky, *et al.*[10] and later verified by Forman *et al.*[4] using the improved data from the 4 Uhuru catalog. As pointed out by Johnson[11], the -0.4 slope does not arise simply from any spiral arm geometry. However, all previous analyses assumed a uniform density distribution, and this is probably not the case. Because of the unique position of the Sun in a locally dense

Table 1 Distribution of X-ray sources with $4 < S < 200$ c.p.s.

Uhuru intensity	No. of sources	Latitude interval	Probability

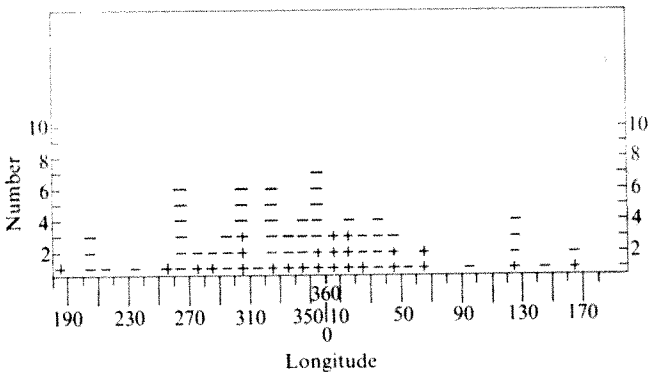

Fig. 1 Distribution of $|b^{II}| < 20°$ sources with $4 < S < 200$ Uhuru c.p.s. Number of sources in 10° longitude bins is plotted. '+', the source lies above the plane; '−', negative galactic latitude. Supernova remnants and clusters of galaxies are excluded.

region of a spiral arm, the density function of B stars *decreases* with increasing distance from the solar neighbourhood, in the region from 300 pc to ~2,000 pc. Although there are subtle variations with galactic longitude due to obscuration and other effects, McCuskey[8] has derived composite density functions which indicate an approximate density $D_s(r) \propto 1/r$ for early B stars. Thus it does not seem inappropriate to assume that a similar function exists for the local X-ray sources. This does not, of course, mean that these X-ray sources are members of typical OB star binary systems but merely that these sources probably have a local distribution function similar to that delineated by the nearby, early type stars. These may be single early type stars whose X-ray emission is due to a stellar wind interacting with the ambient interstellar medium[12], although the X-ray flux ought to be a bit softer than that of a Uhuru source. It is more probable, however, that these objects are similar to Wray 977 (4U1223–62), a 40 c.p.s. source, identified with a $m_v = 11$, B1 supergiant, which has a long (21 d) period, and whose smaller X-ray flux is due to the decreased mass transfer associated with the wide separation of the components. To arrive at a -0.4 slope for $d \log N/d \log S$, $D_s(r)$ will be proportional to $r^{-1.2}$, for the galactic sources distributed in the disk. There are, of course, possibilities that source confusion and source variability can obscure this straightforward view. However, these effects do not seem to change substantially our picture of the extragalactic component[13], which generally contains yet fainter sources and is represented by a steeper $\log N/\log S$ slope, which thereby ought to cause more severe problems than the galactic distribution. Thus it seems that a negative source density gradient in the solar neighbourhood is the most probable explanation of the distribution of the low luminosity X-ray sources.

Differential solar rotation depends on solar activity

SUNSPOTS have long been used as tracers to determine the rotation rate of the Sun. Scheiner[1] noted 250 years ago that low-latitude sunspots rotate more rapidly than those at high latitude ('differential rotation'). In a recent review, Howard[2] stressed the limitations of the sunspot technique for determining rotation rate and differential rotation, as long-lived spots may have substantial individual motions, random and systematic, in both longitude and latitude. For example, leading and following spots of a sunspot group diverge early in the group's lifetime[3]; rotation rates for isolated ('unipolar') spots and groups differ, with group rates depending on the shape of the group[4]. Another problem in using sunspots is the Wilson effect, a surface depression of the spot causing errors in longitude estimates away from the central meridian. Despite these difficulties, spots have been used previously to establish that there is no secular variation in rotation rate and differential rotation, nor any variations with phase of the solar cycle[5], the only possible exception being during long-term disruptions in the solar activity cycle mechanism[6]. We present here evidence to suggest that the first of these conclusions is incorrect, and that differential rotation does depend on the amplitude of the solar cycle, at least for unipolar spots.

The time-averaged differential rotation law for sunspots may be written as

$$\langle\omega\rangle = \alpha + \beta \sin^2\phi + \gamma \sin^4\phi \qquad (1)$$

where $\langle\omega\rangle$ gives the daily angular sidereal motion in terms of solar latitude ϕ. Since sunspots are concentrated to within 30° latitude of the solar equator, the γ term is usually ignored. The most quoted determination for $\langle\omega\rangle$ is that of Newton and Nunn[5], who found from an analysis of sunspot data for the interval 1934 to 1944 that

$$\langle\omega\rangle = 14.38\ (\pm 0.01) - 2.96\ (\pm 0.09) \sin^2\phi \text{ deg per day} \qquad (2)$$

Newton and Nunn used stable recurrent spots in their determination: 174 unipolar spots dominated their analysis, although 89 leader and 8 follower spots of groups were also included. Because of what is known about non-uniform characteristic motions, particularly in groups, Newton and Nunn's comparison of the 1934–44 data with information on earlier cycles (given in refs 7 and 8) may be invalid. Data selection for the earlier cycles seems to have been based on the longevity of spots, irrespective of whether they were unipolar or leaders of groups—the actual fraction of each is not given, although reference is made to 'the large percentage of cases' where spots used were group leaders. Thus the evidence for the long-term invariance of differential rotation is inadequately founded. However Newton and Nunn's result for the invariance during a single cycle apparently stands, despite the small data sample near cycle minimum.

Since Ward[4] found that rotation estimates were a function of spot size and shape, with 'streamers' moving more quickly than 'bipolar' spots, which in turn move faster than unipolar spots, for comparison of daily angular sidereal motion from cycle to cycle it is necessary that only unipolar spots of restricted size range be used. We have done this for three years centred near the maxima of the solar cycles which peaked in 1883–85 and 1956–58, at the extremities of the 80-y 'Gleissberg Cycle'. The annual mean sunspot number at the maximum of the 11-y cycle, R_{max}, for 1956–58 was three times that for 1883–85, R_{max} having increased steadily between the two. Spot sizes were limited to 30 to 300 millionths of the visible solar disk, and latitudes to less than 30°. Although spot positions are available in the '*Daily Results*' and '*Ledgers*' of the Royal Observatory (based on plates taken at Greenwich, and subsequently Herstmonceux, and complemented with plates from Dehra Dûn, Mauritius, Cape of Good Hope, Kodaikanal, and Mt Wilson), all plates and

0028-0836/79/300299—02$01.00

© Macmillan Journals Ltd 1979

prints for the two epochs were individually checked and where necessary spot positions remeasured. An additional selection criterion was spot longevity (at least 10 days). The only relaxation of these conditions was that the short-term appearance of a small companion to a long-lived unipolar spot was ignored. Spot positions within 10° of the limb were not used because of difficulties in determining accurate longitude from a foreshortened image of the spot. A more stringent criterion is needed for estimating the centre-of-gravity for sunspot groups; however we found that for unipolar spots positional estimates were reproducible and accurately determinable beyond 10° of the limb.

The strict application of the above selection criteria severely restricted the data sample to only 1 to 2 spots per month—50 long-lived unipolar spots were found suitable for 1883–85, and 67 for 1956–58. (Extending the time intervals to include spots from near cycle minima would not have significantly increased the data sample size because of the scarcity of long-lived unipolar spots near cycle minima.) The latitude ranges for the data used (combining northern and southern hemispheres, since there is no apparent difference in spot rotation rates, ref. 5) were—

	No. of spots	
Latitude	1883–85	1956–58
0–5°	6	3
5–10°	17	8
10–15°	13	17
15–20°	5	11
20–25°	7	20
25–30°	2	8

A total of 354 spot positions for 1883–85 and 525 positions for 1956–58 were included in the subsequent analysis. A least-squares analysis was used to determine the sunspot rotation relationship for $\phi \leq 30°$.

1883–85 $R_{max} \sim 60$

$$\langle\omega\rangle = 14.372\ (\pm 0.012) - 2.628\ (\pm 0.166)\ \sin^2\phi \quad \text{deg per day} \tag{3}$$

1956–58 $R_{max} \sim 180$

$$\langle\omega\rangle = 14.349\ (\pm 0.011) - 3.367\ (\pm 0.094)\ \sin^2\phi \quad \text{deg per day} \tag{4}$$

In this analysis it was assumed that the spots had a common proper motion in both longitude and latitude, and it was further assumed that the motion in latitude is directed towards the equator. Individual proper motions of the spots were ignored.

It seems that the equatorial rotation rate, α, remained essentially constant over the interval of interest, a result in accord with previous investigations (for example, refs 1–5) when standard errors are accounted for. However, Eddy (personal communication) has detected a variation in equatorial rotation rate between 1890 and 1960 by fitting all Greenwich sunspot group data to a modified rotation law

$$\langle\omega\rangle = a + b\phi + c\phi^2$$

and allowing for spot proper motions fitted to a quadratic. (b lies within the experimental uncertainty of value zero, and may be ignored.) By fitting our data to this same relationship, we confirm our initial finding of constant 'a' for the 1883–85 and 1956–58 maxima. Indeed, only the 1890–1900 cycle in the Eddy analysis shows a value markedly discrepant with our conclusion of constant equatorial rotation rate.

There seems to be a dramatic variation in differential rotation factor β, in the sense that high-latitude spots rotate more slowly with increasing R_{max}. Expression (2) is compatible with such an interpretation, since R_{max} for the 1938–39 maximum was ~110, although it must be stressed that the Newton and Nunn results did include a significant fraction (about one third) of leader and follower spots. A 20% higher estimate for our 'c' value for the 1956–58 maximum compared with Eddy's is compatible with Ward's conclusion regarding the differing behaviour of groups and unipolar spots.

All the above determinations depend on the adopted value of i, the inclination of the solar equator to the ecliptic, and Ω the longitude of the ascending node of the solar equator on the ecliptic. The values used today were estimated by Carrington[9] over a century ago. Recently Wöhl[11] has pointed out that there could be large errors in Carrington's values for i and Ω. The constant of differential rotation β would change if i and Ω were changed. Carrington used the latitude observations of individual sunspots covering an 8-yr interval to derive the constants. Since we have similar data we attempted to re-evaluate the solar elements and the results are shown together with estimates of the internal errors in the table below.

	Present evaluation	Carrington (1863)
i	7.22 ± 0.02	7.25
Ω_{1850}	73.94 ± 0.20	73.67

The present value of Ω is $\Omega_{1850} + 0.01396t°$ where t is the number of years since 1850. The error in Ω is larger than in i because the method enables the quantities $\Omega \sin i$ and i to be determined, and their errors are about equal. These results are in the same sense but much smaller than those predicted by Wöhl[11] who gives a table of previous determinations from sunspots and calculates his own set of elements from Doppler measurements of the solar plasma, which differs considerably from Carrington's values.

In view of the possibility of large systematic errors in the estimation of Carrington's elements, and the small difference in these new values it seems advisable to continue to use Carrington's values published in 1863 until techniques are further improved.

A satisfactory explanation of differential rotation remains a matter of debate—for a recent review see ref. 10. The evidence presented here suggests that any future theory must account for an invariant equatorial rotation rate α, but a differential factor β which varies with the amplitude of the sunspot cycle, at least in the case of unipolar spots.

We thank Miss C. Y. Hohenkerk for assistance with computer programming. We have appreciated discussions with Professor Jack Eddy, and thank him for providing results of his analysis prior to publication.

Origin of the jovian ring and the galilean satellites

THE discovery by Voyager I of a thin flat stream of rocks orbiting Jupiter at a radius of some 130,000 km, or $\sim 2R_P$ ($R_P = 6.677 \times 10^9$ cm = present polar radius), in its equatorial plane opens a new avenue of information in our understanding of the formation of the Solar System. Each of the major planets which possesses a regular satellite system also possesses a ring system. Theories for the formation of the major planets should

0028–0836/79/300300—03$01.00

© Macmillan Journals Ltd 1979

therefore address themselves to this phenomenon of the co-appearance of rings and regular satellite systems, especially in considering the question whether Neptune, which has no regular satellites, may also not have a ring. We suggest here that Jupiter's rocky belt formed through condensation from a gaseous disk which was shed by the rotating gaseous envelope that originally contracted to form that planet. The four galilean satellites were formed from gaseous rings which were shed by the same envelope at an earlier and more turbulent stage in its evolution. It is possible that Jupiter may possess another rocky satellite belt at orbital radius $4R_P$[1].

The regular satellite systems of Jupiter, Saturn and Uranus are remarkable for the near coplanarity and circularity of their orbits. In addition, the orbital radii R_n, when numbered from the outermost members inwards ($n = 0, 1, 2, \ldots$), form nearly perfect geometric sequences

$$R_n/R_{n+1} = \text{constant} = \Gamma \tag{1}$$

where for Jupiter $\Gamma = 1.65$. We have recently[2] suggested that these regular satellite systems were formed in a manner similar to the hypothesis originally advanced by Laplace[3] for the formation of the planetary system; namely, through condensation from a set of gaseous rings which were shed by the primitive contracting gaseous envelopes, which make up the bulk of the mass of these planets[4,5]. Now, although Laplace's hypothesis was largely abandoned over a century ago because of a number of objections[6,7], one of us (A.J.R.P.) has shown these objections can be overcome if one takes into account a supersonic turbulent stress arising from the motions of overshooting convective elements within the cloud[8,9].

The turbulent stress has a radial component given by $\langle \rho_t v_t^2 \rangle = \beta \rho GM(r)/r$ where ρ is the gas density and $M(r)$ the mass interior to radius r, while β is the so-called turbulence parameter[10,11]. Typically, for $\beta \simeq 0.1$ the turbulent stress is some 30 times the normal gas pressure $\rho \mathcal{R}T/\mu$ just beneath the photosurface of the cloud. The main effect of this stress is to cause the gaseous envelope to become very centrally condensed; that is, it drastically lowers the moment of inertia $I \equiv fM_{env}R_e^2$, where M_{env} is the total envelope mass, and R_e is the equatorial radius. Typically, we find $f \simeq 0.01$–0.02. The turbulent stress also leads to the development of a very dense shell of non-turbulent gas at the surface of the cloud. As the cloud contracts to the fully rotating configuration at radius R_0, given where the centrifugal force at the equator first matches the gravitational force there, the dense outer shell evolves into a belt-like structure at the equator. This belt, of mass m, is left behind by the cloud while the latter withdraws dynamically to a smaller radius, stabilising itself rotationally through the extrusion of fresh material to the surface. The gas density of the detached ring diminishes with distance ξ from the mean Kepler orbit R_0 according to

$$\rho(\xi) = \rho_0 \exp(-\tfrac{1}{2}\alpha\xi^2/R_0^2) \tag{2}$$

where $\rho_0 = \alpha m/4\pi^2 R_0^3$ is the density on the mean orbit and $\alpha = \mu GM_{env}/\mathcal{R}T_0R_0 = \mathcal{O}(10^2)$.

The process of shedding gas rings repeats itself at the sequence of orbital radii R_n which satisfy the equations

$$R_n/R_{n+1} = [1 + m/M_{env}f]^2 \tag{3}$$

Thus if the contraction occurs homologously, meaning that both m/M_{env} and f are preserved, then R_n/R_{n+1} is constant and the sequence R_n is geometric. Next, taking $R_n/R_{n+1} = 1.65$ and $f = 0.02$, equation (3) tells us that the masses of the jovian rings were each about the same and equal to

$$m = 1.1 \times 10^{28}\ \text{g}$$

Such a mass of gas of solar composition contains rock and rock + H_2O ice components

$$m_{\text{rock}} \simeq 5 \times 10^{25}\ \text{g}, \quad m_{\text{rock+H}_2\text{O ice}} \simeq 12 \times 10^{25}\ \text{g}$$

The observed masses of the rocky satellites Io and Europa are 9×10^{25} and 5×10^{25} g, respectively, whilst the ice-like satellites Ganymede and Callisto have masses 15×10^{25} and 11×10^{25} g. This suggests that the protojovian envelope probably did shed rings of gas of roughly equal mass equal to that shown above.

To determine the chemistry of the galilean satellites, a turbulent polytropic numerical model of the fully rotating protojovian envelope was constructed having mass $M_{env} = M_J = 1.901 \times 10^{30}$ g. The turbulence parameter $\beta = 0.109$ is chosen so that the Titius–Bode 'constant' $\Gamma = \Gamma(\beta) = 1.65$. During uniform contraction the ratio of surface to central temperatures T_s/T_c is a fixed fraction θ_{ph} of the ratio of surface to central molecular weights μ_s/μ_c. Choosing $\theta_{ph} = 0.003$ we achieve a model where the condensation point for H_2O ice lies between the orbits of Europa and Ganymede, as required by the observational data.

The results of the calculations are summarised in Table 1. There we show the envelope moment-of-inertia coefficient f, the ratio P_s of turbulent stress to gas pressure just beneath the photosurface, and the temperature T_n and density ρ_n on the mean orbit of each gas ring just after the moment of detachment t_n from the planetary envelope, which is measured from initial radius $R_e = 30\ R_P$. We assume that a gas ring was shed at the orbit of each of the satellites and that Callisto's orbit marks the radius R_0 where the contracting envelope first became rotationally unstable. The cloud is energetically stable at each radius because of the turbulent support. The factor f increases slowly to 0.015 during the contraction owing to the steady dissociation of H_2. The final column details the composition of the condensate at each orbit, derived from the chemical condensation sequences computed by Lewis[12].

We note that Io and Europa form from a mixture of hydrous mineral silicates. For Io, the Fe combines with S to form troilite, whilst for Europa the Fe appears as FeO. As the various condensates draw together along the mean orbit of the gas ring to form the satellite, the heat released through their compaction

Table 1 Physical properties of the protojovian envelope and gas rings and the expected composition of the galilean satellites

Satellite	Orbital radius R_n/R_P	Moment-of-inertia coefficient f	Turbulent stress ratio P_s	Temperature T_n(K)	Gas density ρ_n(g cm^{-3})	Time of ring detachment t_n(10^6 yr)	Chemical composition of the condensate
Io	6.3	0.0150	26.1	533	4.4×10^{-4}	14.2	$CaTiO_3$, $MgSiO_3$, Ni, $(Na, K)AlSi_3O_8$, FeS, tremolite, talc
Europa	10.1	0.0148	25.9	338	1.1×10^{-4}	11.4	As above, with FeS → FeO (= 'rock')
Ganymede	16.0	0.0141	24.9	220	2.4×10^{-5}	7.3	rock, H_2O ice
Callisto	28.2	0.0130	23.5	133	4.0×10^{-6}	0.8	rock, H_2O ice

will cause the S as well as H_2O to leach out from the growing satellite's interior. This may account for the copius deposits of S observed on the surface of Io, as well as for the icy plains of Europa. For Europa, the black-body temperature due to the jovian envelope falls below the H_2O ice point some 2.5×10^7 yr after its formation, long after its gaseous ring has evaporated. The satellites Ganymede and Callisto condense below the H_2O ice point in this model and therefore consist of dirty ice.

According to the present theory, the contracting envelope also shed one or two more gaseous rings at orbital radii about $4R_P$ and $2.5R_P$. Why then do there appear to be no major satellites at these interior positions? The answer to this question lies in the rate of settling of the condensate particles compared with the dissipation rate of the gaseous ring. The gaseous rings thermally evaporate over a time scale $t_{evap}\sim10^4$ yr. The condensing particles settle onto the central keplerian orbit R_n of the gas ring over a time $t_{set}\propto 1/\rho_s a^2$ where, at Io's orbit, $t_{set}=10^3$ yr for particles of radius $a=10^{-2}$ cm and mass density $\rho_s=3$ g cm^{-3}. The galilean satellites are therefore expected to contain their full share of condensate. Inside Io, however, where the temperature is higher ($T_n\propto R_n^{-1}$), the particles are less hydrous and more dusty, and therefore more likely to remain suspended in the gas as a fine smoke[13]. In addition, the inner rings are most likely stirred by the increased envelope luminosity, which may also frustrate the settling out process. The mass of segregated rocky material at orbital radii $4R_P$ and $2.5R_P$ may therefore be only a small fraction of the total mass of condensate (about 5×10^{25} g) which existed at each of these orbits. If, further, this settled mass is less than $\sim2\times10^{18}$ g in the case of a protojovian envelope having $f=0.015$, or less than 2×10^{21} g for $f=0.02$, there will be insufficient time for the rocks to aggregate into a single body before the gaseous component of the ring disperses, taking with it the finer material. These mass bounds are consistent with the fact that so far no satellites have been detected at these orbits.

It is possible that the tiny satellite Amalthea (mass $\geq10^{21}$ g, orbital radius $\sim2.72R_P$) somehow formed from the ring near $2.5R_P$. But the dark red spectral features of this body[14], which suggest a composition similar to C-type asteroidal material, together with the absence of any corresponding satellite at $4R_P$, raises instead the more likely possibility that Amalthea is a stray asteroid captured by Jupiter at some time after its formation.

The process of shedding gas rings cannot proceed indefinitely as a uniform contraction of the outer layers of the cloud would lead to unrealistically high surface temperatures T_s. Instead we suggest, following the non-turbulent cloud calculations of Graboske *et al.*[15], that soon after radius $R_c=3R_P$ has been passed, where $T_s=1{,}120$ K, T_s begins to downturn and level off to ~600 K by radius $1.5R_P$. Now, a downturn in T_s implies a slowing down in the rate of release of gravitational energy $d\Omega/dt\propto R_c^2T_s^4$ and hence a diminution in the degree of supersonic turbulent convection in the cloud. But such a drop in turbulence also leads to a closer spacing between the rings of gas, as a weakly turbulent cloud is unable to support as much material at the equator. Computationally, we find that as T_s falls from 1,120 to 600 K, that β falls from 0.11 to 0.07 and $\Gamma=R_n/R_{n+1}$ drops sharply from 1.65 to 1.02 during the contraction from radius $R_c=3R_P$ to $1.5R_P$, for a cloud which maintains the same $f=0.015$. For $R_c\leq2.5R_P$ the rings are so closely spaced that they essentially merge together to form a continuous disk. Any largish grains condensing out in this dense ($\rho\sim3\times10^{-3}$ g cm^{-3}) gaseous keplerian disk settle onto the mid-plane to form a rocky sheet. Owing to the vigorous thermal stirring likely to be present in the gas, however, the mass of this solid disk is again likely to be much less than the total available condensate mass $\sim2\times10^{25}$ g. The disk is unable to coalesce into a few single bodies owing to its differential rotation[16,17]. After the gaseous component of the disk has dispersed, orbital resonances and other tidal phenomena[18] lead to evolutionary changes in its structure, which may account for the observed sharp inner edge at radius $1.9R_P$.

Optical absorption coefficients of water

THE absorption spectrum of water in the visible region has been widely investigated[1–9] because of the basic, technological and environmental importance of liquid water. Despite these efforts, there are significant disagreements between experimental results: discrepancies of factors of ~2 in the absorption coefficients are not uncommon between various data. Possible reasons for the disagreements among the various studies are: (1) a lack of a reliable, sensitive technique for measuring small absorpton coefficients in liquids; (2) the presence of a significant amount of light scattering by particles (note that the amount of Rayleigh scattering by pure water is quite small and predictable in the visible[8]; and (3) measurements are often not done for pure distilled water stored in a noncontaminating vessel. We present here the first accurate measurement of the absorption coefficient of pure water at 21 °C in the 450–700-nm region. We have utilised a recently developed opto-acoustic (OA) technique[10], using pulsed dye lasers and immersed piezoelectric transducers. This technique is ideally suitable for measuring weak linear or nonlinear absorptions in nonfluorescing neat liquids or solutions[11,12]. Our present absorption spectra for water, having typical accuracies of ±5%, should be useful not only for a basic understanding of the properties of water, but also for practical applications like underwater light propagation or intracavity dye laser measurement of dissolved materials in aqueous solutions.

We used the OA cell shown in Fig. 1. There are several important changes to the cell previously used for benzene[10]. We have designed a special transducer with a stainless steel casing which has a flat polished inside surface against which a lead zirconate titanate (PZT) cylinder is pressed. (Details of the cell's construction and its operation will be published later.) This transducer is superior to the commercially available transducers

0028-0836/79/300302—03$01.00

which we previously used because the possibility of contamination of the water sample and the formation of small air bubbles on the transducer surface are eliminated. The OA cell is filled with triple-distilled deionised water. Since the coefficient of thermal expansion of water changes drastically with temperature[13], a small chromel–alumel thermocouple in contact with the water is used to monitor the water temperature which is stabilised at 21.5 ± 0.2 °C for the present experiments. This is necessary since the OA signal arising from the absorption of the optical radiation depends crucially on the coefficient of thermal expansion of the liquid as seen from equation (3) of ref. 10. An expansion tube is attached to the side of the OA cell to ensure that the water sample is at atmospheric pressure. With the above precautions, no contamination problems were encountered, and the OA spectrum was reproducible for a freshly distilled water sample as well as for the same sample stored in the OA cell for several weeks. To obtain the absorption spectrum, a flashlamp-pumped dye laser that can scan through the visible region (with various laser dyes) was used. The OA signal amplitude, A, is detected by the submersed transducer, and the laser pulse energy, E, is detected by a pyroelectric detector as the laser frequency, ν, is scanned by a stepping motor drive. A minicomputer collects the data and plots A/E as we scan ν. The normalised OA spectrum is directly proportional to the actual absorption spectrum[10] (note that conventional spectrophotometry measures absorption plus scattering, while here we only measure absorption). The proportionality constant can be obtained by a comparison method[11,12]; that is comparing the OA signal for pure water with the OA signal for an aqueous solution (water doped with a known small amount of nonfluorescing dye). In the present experiment, $KMnO_4$ is used as the nonfluorescing dye[14]. Absolute absorption coefficient at 659.9 nm is measured to be $(3.7 \pm 0.3) \times 10^{-3}$ cm^{-1}.

The OA absorption spectrum of distilled water at 21.5 °C is shown in Fig. 2, which exhibits a minimum at 21,050 cm^{-1} (475 nm) with a minimum value of α (21,050) = 1.7×10^{-4} cm^{-1}. It also exhibits distinct shoulders at 19,460 cm^{-1} and at 16,550 cm^{-1}. These shoulders, which are absent in heavy water[3], are due to sixth and fifth harmonics of the O—H stretch, respectively (being analogous to the absorption peaks observed in liquid benzene[15] due to the harmonics of the C—H stretch). We found that the nth harmonic absorption peak (or shoulder) in water is reasonably well given by the following simple anharmonic formula

$$\nu_n = n(3{,}620 - 63n) \quad \text{cm}^{-1} \qquad (1)$$

The comparison of experimental peak or shoulder positions in water with the predicted position by equation (1) is given in Table 1.

A comparison of our OA absorption spectrum with attenuation of absorption spectra given by other authors is given in Fig. 2. Of special interest is a comparison with the most recent data of Querry *et al.*[9] who performed a split laser pulse attenuation

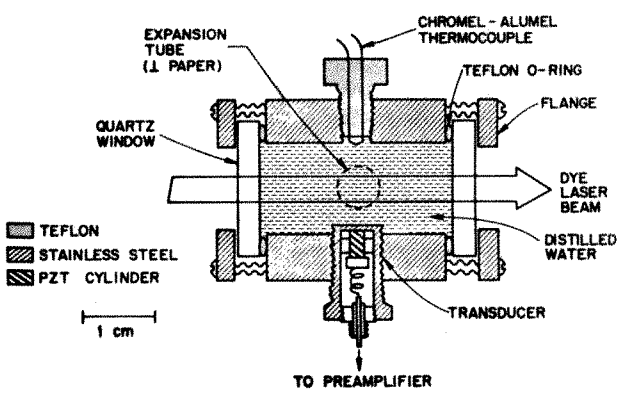

Fig. 1 Experimental OA cell for distilled water.

measurement on deionised filtered water. The spectral features exhibited by our data and the data of Querry *et al.* are strikingly similar, except that their attenuation coefficient is displaced upward by about 2×10^{-4} cm^{-1} from our absorption coefficient. Our data agree reasonably well with the review compilation of Irvine and Pollack[5], and of Hale and Querry[6] in the blue region (450–500 nm) but agreements at some points outside this region are sometimes poor. Agreements with Hulbert's[2] absorption data and Hass and Davisson's[8] adiabatic laser calorimetry measurements for distilled water in the blue are also good; however, their absorption coefficients are significantly lower than our values at longer wavelengths. The critical compilation of Kopelevich[7] seems strongly to underestimate the absorption in the 400–500-nm range.

In conclusion, we believe we have reported the first reliable absorption spectrum of pure distilled water at 21.5 °C. The absorption spectrum does not change appreciably from 20 to 30 °C. An overall comparison of the data by various authors indicates a broad absorption minimum near 475 nm. However, some values differ by as much as an order of magnitude. Agreement on the red side of the 600-nm region is much better and the existing data agree with our measurements to ±20%. Our presently reported data are believed to be the most reliable values so far. There are no clear-cut explanations for the large difference among the previous measurements themselves and for the differences between the previous measurements and our present ones. However, we suggest the following problems with the earlier optical transmission studies which measure extinction coefficients. (1) Conventional optical transmission measurements for pure water require long path lengths because of small absorption coefficients. To extract an absorption coefficient from such a transmission measurement, attenuation caused by scattering must be taken into account. Light scattering by suspended small particles can often be significant compared with the true absorption in the blue region. Accurate accounting of such light scattering effect is difficult. (2) Corrections are necessary for absorption and reflection losses at the optical windows. (3) Possible lateral displacements of the optical beam by water sample causes systematic errors. (4) Long cells may often require use of materials which may add contaminants to the pure water. The previous transmission measurements typically require corrections from (1) and (3) above and some authors probably over-correct their data while others under-correct their data. None of these problems limit the reliability of the measurements reported here since the OA technique measures true absorption directly and the careful construction of the OA cell out of primarily stainless steel has very nearly eliminated contamination problems.

The only possible source of error in our measurements exists in the fundamental requirement for quantitative OA spectroscopy that the optical absorption must only result in nonradiative decay producing heat (but no fluorescence or chemical changes). The above requirement is met in our present OA measurements of water and is justified on two considerations: first, vibrational relaxation of polyatomic molecules in liquid state at room temperature is known to proceed on a

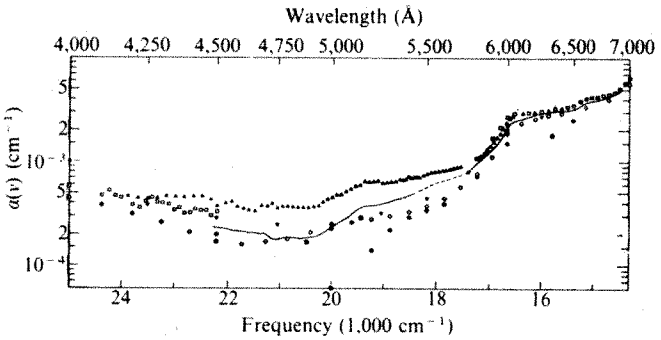

Fig. 2 Absorption spectrum of triple distilled deionised water by OA determination (solid line). The dashed parts are interpolations not covered by the tuning range of the laser dyes used. Also shown are experimental data of other authors for compaison: ◇, ref. 2; □, ref. 3; ◆, ref. 5; ▽, ref. 6; ●, ref. 7; ⊗, ref. 8; △, ref. 9. Statistical accuracy of our data is about ±5%. The uncertainty in the absolute calibration (which does not affect the shape of the curve) does not exceed ±10%.

picosecond time scale[16]. Molecules excited to high vibrational level (high harmonics) are expected to relax even faster as exemplified in the case of benzene[17]. Second, fluorescence yield is negligible unless there is a substantial Frank–London overlap between the singlet ground state and the singlet excited electronic state. The lowest known excited electronic state of H_2O is a triplet ($^3A_2$) situated at[18,19] about 36,300 cm^{-1} (275 nm). Thus the observed absorption in the visible region ($\lambda > 400$ nm) does not involve electronic excitation. Thus no excited electronic states of H_2O which could fluoresce to the ground state are produced in the present experiment. No fluorescence was experimentally observed in the water samples during our studies. Prominent spectral features are due to harmonics of the O—H stretch and seem to be represented reasonably well by the simple anharmonic formula given in equation (1). No other fine structures in the spectrum (which we measured in high resolution) are found, in agreement with Drummeter and Knestrick.[4] Detailed tabulation of the absorption coefficients of light and heavy water as well as further details of the comparison between existing data and our new measurements will be given elsewhere[20].

We thank R. J. Kerl for technical assistance and T. D. Harris for stimulating discussions.

Two-photon absorption spectra and cross-section measurements in liquids

THE recently developed high-sensitivity opto-acoustic (OA) absorption measurement technique[1] has proved ideal for the measurement of a variety of weak absorption phenomena in liquids[2–4]. We report here the results of an investigation of two-photon absorption in liquid benzene using the OA technique. Weak two-photon spectra (cross-section $\lesssim 10^{-51}$ cm^4 $molecule^{-1}$ $photon^{-1}$ s) in nonfluorescing liquids have been difficult to measure. The only previous published study for such a measurement used thermal blooming[5], which is difficult to interpret theoretically and apparently produces a poor signal-to-noise ratio. We demonstrate here that far superior spectra can be obtained by the simple and sensitive two-photon OA spectroscopy (TPOAS) technique. Polarisation dependence, vibrational intervals and electronic origin are obtained, and two-photon absorption cross-sections are derived for the first time in this study for the case of a weak two-photon absorption band in liquid benzene. Note that Bonch-Bruevich *et al.*[6] have recently attempted similar two-photon OA measurements, but they can only measure strong absorption (cross-section $\gtrsim 10^{-48}$ cm^4 $molecule^{-1}$ s) with a poor signal-to-noise ratio.

The two-photon absorption we study here is the $B_{2u} \leftarrow A_{1g}$ transition of benzene[7] which is symmetry forbidden but becomes allowed in two-photon absorption due to vibronic coupling. The $B_{2u} \leftarrow A_{1g}$ transitions have been extensively studied in vapour phase benzene[8–14] by fluorescence monitoring. In the liquid phase, however, fluorescence studies are severely hampered by the rapid nonradiative singlet to triplet relaxation[15,16] ($>4\times10^7$ s^{-1} in liquid benzene at room temperature). Quantum fluorescence yield[15] of the singlet excited state is small (<0.07) and decreases rapidly with vibrational energy[9,10]. The triplet state produced also undergoes rapid nonradiative decay[17–19] to the ground state ($\gtrsim 10^7$ s^{-1} in liquid benzene at room temperature). Thus no fluorescence monitoring of the $B_{2u} \leftarrow A_{1g}$ band in neat benzene at room temperature seems possible. TPOAS is ideal for measuring such weak two-photon spectra in nonfluorescing liquids. The $B_{2u} \leftarrow A_{1g}$ two-photon spectrum we obtain in the liquid resembles the corresponding vapour phase spectrum[8–13]; similarities include strong intensities of the $14_0^1 1_0^n$ vibronic transitions, laser polarisation dependence, and nearly identical values for ν_{18}, ν_{14} and ν_1 of the $^1B_{2u}$ state in the liquid as in the vapour case. However, the following differences are noted: (1) the electronic origin is 37,724 cm^{-1} in the liquid phase, compared with [7–11] 38,086 cm^{-1} in the vapour phase; (2) the absorption lines are broader (by a factor of ~10) in the liquid as compared with the vapour case[9,10] so that the rotational branches are unresolved; and (3) since fluorescence quantum efficiencies rapidly drop with higher vibrational excitation[9] even in the vapour phase, the two-photon spectra by fluorescence monitoring[8–13] shrink and vanish rapidly at higher vibrational excitation; this does not occur in our case.

The experimental apparatus used includes a scanable Chromatix CMX-4 flash-lamp pumped dye laser which provided the following tuning ranges with the Exciton dyes: Coumarin 2: 448–476 nm; LD 473: 469–500 nm; LD 490: 485–516 nm; Coumarin 504: 502–538 nm. Typical pulse energies of 2 mJ and bandwidth of 2 cm^{-1} with pulse durations of 1 μs were available at 10 pulses s^{-1}. Output beam diameter was 3 mm. A 5-cm focal length lens was used to focus the laser beam at the centre of a cylindrical stainless steel OA cell[1] (1 cm i.d. and 2 cm length), fitted with quartz windows and filled with distilled spectrograde benzene. A quarter-wave plate allows us to convert the normally linearly polarised laser beam to a circularly polarised one for appropriate studies. The transient ultrasonic signal produced by the two-photon absorption was detected by a submersed PZT transducer[1]. The transducer

0028–0836/79/300304—03$01.00

© Macmillan Journals Ltd 1979

consisted of a 4 mm diameter × 4 mm high lead zirconate titanate (PZT) cylinder (LTZ-2 from Transducer Products, Connecticut). To obtain good reproducibility, it is essential that there should be no small microbubbles on the transducer face. The transducer signal and the square of the input laser pulse energy were measured with boxcar integrators. part of the dye laser output was analysed with a 2-m grating spectrometer. Either a Rb lamp or Ar laser lines provided markers for accurate calibration.

Figure 1*a* shows an OA spectrum of benzene in the 18,600 cm^{-1} to 22,200 cm^{-1} region obtained with linearly polarised radiation from the dye laser. The OA signal is normalised to the square of the input power. The seven peaks marked a, b, c, d, e, f, and g are identified as arising from the $B_{2u} \leftarrow A_{1g}$ two-photon absorption. The spacings between the peaks b, c, d, e, f, and g, are approximately 462 cm^{-1} which is in excellent agreement with the expected value of $\nu_1/2$. There are subsidiary small peaks between the major peaks and these are marked by A, B, C, D, and E. Table 1 compares the positions of these peaks with those observed in the high resolution study of two-photon absorption in vapour phase benzene. In order to make a satisfactory comparison, we have to choose the $B_{2u} \leftarrow A_{1g}$ electronic origin at 37,724 cm^{-1}. The identifications and the assignments seem to be consistent and reasonable.

The region of 18,600–22,200 cm^{-1} has two expected weak linear absorption regions arising from the seventh and the eighth harmonic of C—H stretch of benzene. We have studied the seventh harmonic at 18,810 cm^{-1} earlier[3]. This peak was mistaken as a two-photon peak by Twarowski and Kliger[5]. However, the input power dependence of this peak is found to be 1.05 ± 0.08 which indicates that input power dependence of the various peaks are necessary for correct identifications. Table 1 lists the measured input power dependence of the various peaks, obtained with the 5-cm focal length lens.

To further distinguish between the one-photon and two-photon absorption in benzene in our tuning range, we have also investigated the OA spectrum with no focusing lens. The resultant decrease in the light intensity (by a factor of 10^5) makes two-photon absorption unobservable while the linear absorption signal which is independent of intensity is unaffected. In these conditions only two absorption peaks are detected by the transducer with amplitudes depending linearly on input power and whose positions are $18{,}810 \pm 3$ cm^{-1} and $21{,}040 \pm 7$ cm^{-1}. These are identified as the seventh harmonic[3] and the eighth harmonic[20] of the C—H stretch of benzene, respectively. The peak height of the eighth harmonic at 21,040 cm^{-1} is $\leqslant 10\%$ of the two-photon peak at 21,031 cm^{-1} observed with the focusing lens. Thus the two-photon spectrum is essentially undistorted by the presence of the underlying single photon absorption.

We now estimate the absolute peak magnitude of the two-photon absorption cross-section for linear polarisation (peak c at 20,106 in Fig. 1*a*) by comparing it with the one-photon absorption peak X at 18,810 cm^{-1}. At a fixed laser pulse energy of 1.8 mJ, we observe that the ratio of the transducer signals U_c and U_X at peaks c and X respectively is

$$U_c/U_X \approx 3 \tag{1}$$

Since all the nonradiative lifetimes involved are shorter than 100 ns, while the laser pulse is 1 μs long, we assume that all the absorbed light energy is transformed into heat at the end of the laser pulse, causing local thermal expansion, which produces the transducer signal. The amplitude of the transducer signal depends linearly[1] on the light energy absorbed per unit length multiplied by an effective path length l. For the two-photon absorption case, l is taken to be twice the confocal length, that is $l_c \approx 0.05$ cm in our case. For the linear absorption case, l is taken as the laser path length directly in front of the transducer, that is $l_X \approx 0.4$ cm. Hence we have

$$U_c \approx K \times \sigma_c N l_c \int \Phi(t) P(t)\, dt \tag{2}$$

and

$$U_X \approx K \times \alpha_X l_X \int P(t)\, dt \tag{3}$$

where integrals are performed over the duration of the laser pulse, K is a constant, $N = 6 \times 10^{21}$ cm^{-3} is the molecular density, σ_c is the two-photon cross-section at peak c, $\Phi(t)$ is the instantaneous photon flux, $P(t)$ is the instantaneous power, and α_X is the peak absorption coefficient of the seventh harmonic of the C—H stretch, observed[3] to be $(4.5 \pm 1.0) \times 10^{-4}$ cm^{-1}. § Ref. 3.

‖ This peak can be seen only without a focusing lens; details of this linear absorption peak is given in ref. 20.

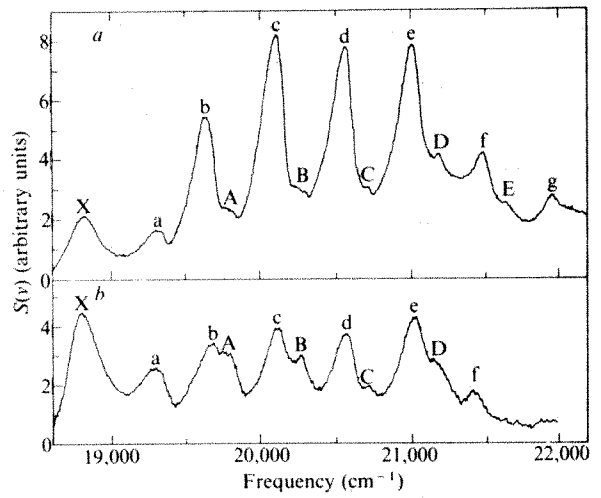

Fig. 1 Normalised two-photon spectra of liquid benzene for the $^1B_{2u} \leftarrow {}^1A_{1g}$ band. ν is the single photon energy, and $S(\nu)$ is the transducer signal amplitude normalised to the square of the laser pulse energy. Note that the absorption peak at 18,810 cm^{-1} is not a member of this band, but is the peak of the seventh harmonic of the C—H stretch. *a*, Spectrum for linear laser polarisation. *b*, Spectrum for circular laser polarisation, magnified by a factor of 2.5 compared with the spectrum in *a*.

laser pulse energy $E = \int P(t)\,dt$ is fixed at 1.8 mJ and the average $\Phi(t)$ is estimated to be 1.4×10^{27} photons $cm^2\,s^{-1}$. Note that U_c as given in equation (2) is independent of the focal length of the lens used, since tighter focusing results in a correspondingly shorter confocal length, l_c. This was verified experimentally for focal lengths of 2.5, 5 and 7.5 cm. Combining equations (1)–(3), we estimate that

$$\sigma_c \approx 1 \times 10^{-51}\ cm^4\ molecule^{-1}\ photon^{-1}\ s \qquad (4)$$

with an uncertainty of a factor of 3. The two-photon absorption cross-sections for other peaks in Fig. 1*a* can be scaled appropriately, as given in Table 1.

Judging from the signal-to-noise ratio in Fig. 1*a*, we note that the minimum two-photon cross-section presently detectable is $\sim 10^{-53}\ cm^4\ molecule^{-1}\ photon^{-1}\ s$. Also, since our OA signal becomes small near 18,500 cm^{-1} (Fig. 1*a*), we believe that possible broadband spurious effects (such as the laser electrostriction[22] effect) are negligible in our present study.

Finally, the use of circular polarisation (as opposed to linear polarisation used in the data reported above) has allowed us to obtain further check on our identification of the two photon transitions listed in Table 1. From vapour phase benzene two-photon absorption data we see that R, defined as the ratio of two photon absorption coefficient for linear polarisation to that for circular polarisation, has well defined values for various vibronic two-photon transitions in benzene. Theoretical considerations show[9,10,23] that the A_{1g} vibronic transitions should exhibit a ratio R of 5.7 (averaged over the rotational band) while the E_{2g} vibronic transitions should exhibit a ratio R of 0.66; the theory is well supported by experimental investigations in the gas phase[9,10] and in the crystalline phase[24]. For the liquid phase, the circularly-polarised TPOAS spectrum is shown in Fig. 1*b*, where the vertical scale is magnified by a factor of 2.5 compared with Fig. 1*a* to bring out the features. Note that (1) the relative heights of the various peaks are quite different and that for the A_{1g} vibronic transitions (for example, peak b or c) $R \approx 4 \pm 1$, while for the E_{2g} vibronic transitions (for example, peak a or A) $R \approx 1 \pm 0.3$ in reasonable agreement with theory[9,22]; and (2) the position of an A_{1g} transition peak is blueshifted (typically by 20 cm^{-1}) for circular polarisation as compared with the linear polarisation case, since different rotational branches are favoured for the different polarisations[9,10]; however, no shifts are observed for the E_{2g} transition peaks. However, we should emphasise that most theories of liquids do not treat molecules as being freely rotating and isolated as they would be in the gas phase, and hence the comparison between the effect of rotational structure in gas phase and liquid phase may not be strictly valid.

We have shown that TPOAS, utilising pulsed lasers and submersed transducers, represents a very powerful tool for the study of two-photon absorption spectra of non-fluorescing liquids. By this method, accurate two-photon spectroscopy of the $^1B_{2u}$ state of benzene in the neat liquid is studied with quantitative cross-sections derived for the first time. The selection rules for two-photon absorption are very different from those for one-photon absorption (at about twice the photon energy). Thus the TPOAS allows us to find and to determine the positions of vibronic levels not possible in single photon spectroscopy. We plan to extend these studies to multiphoton absorption and ionisation phenomena in various liquids.

We thank R. J. Kerl for technical assistance, and M. B. Robin for suggestions.

Photocatalytically induced fixation of molecular nitrogen by near UV radiation

A MAJOR method whereby molecular nitrogen is fixed in the soil is through microorganisms[1]. Recently, however, molecular nitrogen has been shown[2] to react with water vapour in the presence of TiO_2 under the stimulus of near UV radiation to produce ammonia and hydrazine according to the photoreducing reactions summarised as:

$$N_2 + 3H_2O \xrightarrow[TiO_2]{h\nu(\lambda \geq 365\ nm)} 2NH_3 + 3/2O_2 \qquad (1)$$

$$N_2 + 2H_2O \xrightarrow[TiO_2]{h\nu(\lambda \geq 365\ nm)} N_2H_4 + O_2 \qquad (2)$$

We report here the results of some recent experiments in which molecular nitrogen has been fixed, at room temperaure in oxidising conditions, on the surface of rutile (TiO_2) by low-energy UV photons.

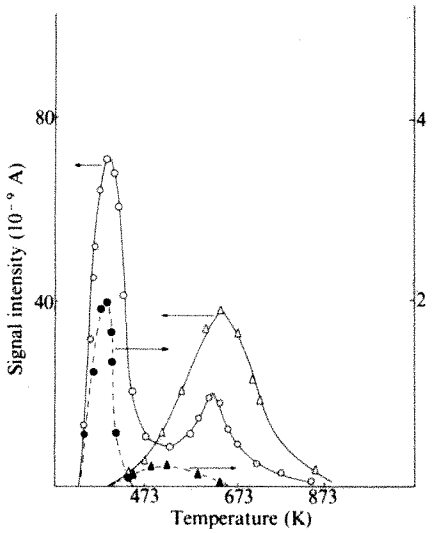

Fig. 1 Temperature programmed desorption profiles of TiO_2 surfaces: solid line, following the interaction of 20 Nm^{-2} of molecular nitrogen with a surface saturated with pre-adsorbed hydrogen peroxide; dashed line, following exposure to UV radiation ($\lambda \geq 365$ nm) in the presence of air. (The saturated surface containing $\sim 1.2 \times 10^{8}$ molecule m^{-2} of H_2O_2 was produced by adding an aqueous solution of H_2O_2 (Analar 30% w/v) to the outgassed rutile surface, followed by evacuation to remove the excess liquid.) ○●, $m/e = 32$; △▲, $m/e = 30$. For solid symbols, read right-hand scale; for open symbols, read left-hand scale.

TiO_2 powders, which contain adsorbed water, show significantly greater photochemical reactivity towards oxygen than specimens which have been dehydroxylated. It has been suggested[3] that the adsorbed hydroxyl groups, OH^-_{ads}, act as traps for the positive holes, h^+_{vb}, which are formed in the valence band of the TiO_2 when it is irradiated with photons of energy equal to or greater than the magnitude of the electronic band gap (E_g (TiO_2) ~ 3.2 eV) according to the mechanism:

$$TiO_2 + h\nu (E_g \geq 3.2 \text{ eV}) \rightarrow h^+_{vb} + e^+_{cb} \quad (3)$$

$$h^+_{vb} + OH^-_{ads} \rightarrow \dot{O}H_{ads} \quad (4)$$

The hole trapping leaves the conduction band electron, e^-_{cb}, available to interact with the ambient atmosphere and the chemisorption of molecular oxygen takes place according to:

$$e^-_{cb} + O_2 \rightarrow O^-_{2ads} \quad (5)$$

Much information has been obtained about the nature of the adsorbed species O^-_{2ads} (ref. 4), but the identification of the hydroxyl radical has been much more difficult to confirm due to its high reactivity, although there is indirect evidence[5] of its existence.

In a recent series of experiments we have used the technique of temperature programmed desorption (TPD) in conjunction with mass spectrometry and gas–liquid chromatography to investigate the surfaces of rutile powders, which contain pre-adsorbed water, following their exposure to prolonged irradiation (300 min) with near UV photons ($\lambda \geq 365$ nm) at room temperature in the presence of either pure oxygen or air. (These rutile powders, supplied by Tioxide International Ltd, contained 99% rutile with a specific surface area of 13 $m^2 g^{-1}$ as determined by krypton adsorption at 78 K.)

A comparison of the desorption spectra from these surfaces, following the irradiation treatment, with that arising from a TiO_2 surface containing pre-adsorbed hydrogen peroxide only, shows a correspondence between the molecular oxygen peaks in the respective profiles (Fig. 1). These results indicate that hydrogen peroxide is formed on the surface of the TiO_2 powder during the irradiation, probably through the direct interaction of the hydroxyl radicals which form during the hole trapping process:

$$H\dot{O}_{ads} + \dot{O}H_{ads} \rightarrow H_2O_{2ads} \quad (6)$$

A remarkable aspect of the desorption spectra from these surfaces is the appearance of a gaseous molecular species which from its mass cracking pattern ($m/e = 30$, 14, 16) and the relative peak intensity ratios of 100:6:1 has been identified as nitric oxide. In the case of surfaces containing pre-adsorbed hydrogen peroxide the nitric oxide appears only after exposing the surface to molecular nitrogen or to air. Similar effects are observed if the TiO_2 surfaces are irradiated in pure oxygen, whereas it seems that the nitric oxide forms directly if the irradiation takes place in air or a nitrogen–oxygen mixture. The quantity of nitric oxide desorbed from the surface saturated with pre-adsorbed hydrogen peroxide (Fig. 1) corresponds to a coverage of approximately 3×10^{17} molecule m^{-2}.

The surface species from which the nitric oxide arises has not yet been identified but it has been clearly demonstrated that molecular nitrogen reacts with adsorbed hydrogen peroxide (Fig. 2) and it is therefore most probable that nitric oxide arises from the direct interaction of molecular nitrogen with a species originating from the adsorbed hydrogen peroxide. Moreover it had been established that hydrogen peroxide is formed on the surface of TiO_2 (rutile) when oxygen, water and UV radiation are present simultaneously and that molecular nitrogen can be fixed at the surface of the TiO_2 through its interaction with the hydrogen peroxide which has been photosynthesised *in situ*.

Molecular nitrogen is thought to react with a species of atomic oxygen, either O_{ads} or O^-_{ads}, which originates from either the thermal or photochemical decomposition of the adsorbed hydrogen peroxide, as the interaction of molecular nitrogen with hydroxyl radicals is energetically very unfavourable[6],

$$N_2 + OH \rightarrow NO + NH \qquad \Delta H^{\ominus}_{298} = +387 \text{ kJ mol}^{-1} \quad (7)$$

We believe that the adsorbed species from which the gaseous nitric oxide originates is probably an adsorbed form of molecular nitric oxide, or one of its ions, and is created by a mechanism of the type shown in equations (8)–(11):

$$H_2O_{2ads} \rightarrow H_2O_{ads} + O^*_{ads} \quad (\text{where } O^*_{ads} \text{ is } O_{ads} \text{ or } O^-_{ads}) \quad (8)$$

$$N_2(g) + O^*_{ads} \rightarrow NO^*_{ads} + N_{ads} \quad (9)$$

$$N_{ads} + O^*_{ads} \rightarrow NO^*_{ads} \quad (\text{where NO}^* \text{ is } NO_{ads} \text{ or } NO^-_{ads}) \quad (10)$$

or

$$N_{ads} + O_{2ads} \rightarrow NO^*_{ads} + O_{ads} \quad (11)$$

X-ray photoelectron spectroscopic (XPS) examinations of the surfaces of these TiO_2 specimens show nitrogen (1s) signals at a

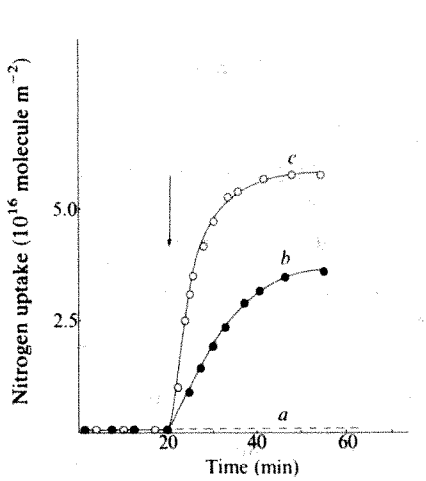

Fig. 2 The interaction of molecular nitrogen with hydrogen peroxide vapour at the surface of TiO_2 (rutile) at 298 K. *a*, TiO_2 absent; *b*, initial pressure of nitrogen = 3.3 N m^{-2}; *c*, initial pressure of nitrogen = 20.0 N m^{-2}. Arrow indicates hydrogen peroxide vapour admitted.

binding energy of 399.5 eV, confirming the presence of an adsorbed species containing nitrogen. In the experiment with pre-adsorbed hydrogen peroxide, the saturation coverage of the nitrogen species was estimated from the XPS data to be of the order of 10% of a monolayer, but it is not possible to decide whether the N(ls) signal originates from adsorbed nitric oxide or from a diatomic nitrogen species. Nitric oxide adsorption at 298 K (ref. 7), on oxidised TiO_2 surfaces, produces two irreversible states of adsorption having maxima in the desorption profile at 450 K and 660 K respectively. It is the stronger state of adsorption of nitric oxide to which the fixed nitrogen most closely corresponds. Electron paramagnetic resonance studies of the samples containing the fixed nitrogen failed to detect any species which could be ascribed to adsorbed molecular nitric oxide and we conclude that the adsorbed species is probably NO^-_{ads} (or $N_2O^{2-}_{2ads}$) as enhancement in the uptake of molecular nitrogen suppresses the formation of the species, O^-_{2ads} (ref. 7) which arises from the decomposition of the adsorbed hydrogen peroxide. In addition no mass spectrometric evidence has been found in the temperature programmed desorption profiles for the existence of molecules of N_2O or NO_2.

Titanium dioxide surfaces are probably not unique in being able to participate in the photocatalytic fixation of molecular nitrogen as many other solids exhibit photocatalytic properties[8]. The adsorbed nitrogen species formed during the fixation reaction may itself undergo further oxidation to a more stable species, such as the NO_2^- ion[9], and it seems likely that these processes can occur naturally at the Earth's surface under the stimulus of sunlight.

We thank Professor M. W. Roberts and A. F. Carley for the XPS data and acknowledge support of Tioxide International Ltd.

CS_2 and COS in the stratospheric sulphur budget

THE persistence and pervasion of the stratospheric sulphate (Junge) layer[1,2] during periods of low volcanic activities have puzzled many aeronomers. Junge[3] suggested that sulphur dioxide, SO_2, is probably the gaseous precursor for the sulphate layer. The origin of stratospheric SO_2 is, however, uncertain. The gas may originate from the troposphere through upward diffusion processes[3], while Crutzen[4] recently suggested that the presence of SO_2 in the stratosphere may be attributed to photolysis of carbonyl sulphide, COS. Recent measurements[5] showed that the mixing ratio of SO_2 remains remarkably constant in the upper troposphere and the lower stratosphere region. We show here that such peculiar phenomena may be explained by oxidation of COS and carbon disulphide, CS_2. The gas, CS_2 has been detected by Lovelock[6] in seawater samples, and by Sandalls and Penkett[7] in the lower troposphere. We[8] recently argued that CS_2 may be a precursor for atmospheric COS. Here we investigate the possible role of COS and CS_2 in the stratospheric sulphur budget and account for the source for stratospheric sulphate, the observed distributions of SO_2 and COS.

Table 1 Chemical model

Ref	Reaction	Rate constant*
9, 10	$CS_2+OH \rightarrow COS+HS$	$R1 = 1.9(-13)$§
11	$CS_2+O \rightarrow CS+SO$	$R2 = 3.7(-11)\exp[-700/T]$
	$\rightarrow COS+S$	$(fa = 0.8, fb = 0.1, fc = 0.1)$†
	$\rightarrow CO+S_2$	
12	$CS_2+h\nu \rightarrow CS+S$	$J3$‡
26	$COS+h\nu \rightarrow CO+S$	$J4$‡
9, 10	$COS+OH \rightarrow CO_2+HS$	$R5 = 5.7(-14)$§
27	$COS+O \rightarrow CO+SO$	$R6 = 1.6(-11)\exp[-2250/T]$
17	$SO_2+OH+M \rightarrow HSO_3+M$	$R7 = \frac{8.2(-13)\times[M]}{7.9(+17)+[M]}$
28	$SO_2 \rightarrow$ precipitation and scavenging	$R8 = 5.8(-7)Z < 10$ km

* The rate constants are in units of $cm^3\ s^{-1}$ for two-body reaction, $cm^6\ s^{-1}$ for three-body reaction and s^{-1} for photolysis rates and $R8$.
† *fa*, *fb* and *fc* are the relative yields for the three branches.
‡ The photolysis rates are calculated from measured cross-sections allowing properly for diurnal variation of solar intensity.
§ These are room temperature values[9]. The activation energy for $R1$ and $R5$ should be negligible based on proposed reaction mechanism[10].

The atmospheric sinks for CS_2 are,

$$CS_2+OH \rightarrow \left[\begin{matrix}S-C-S\\ \quad\ |\\ \quad OH\end{matrix}\right]^* \rightarrow COS+HS \quad (1a)$$

$$\rightarrow CS+SOH \quad (1b)$$

$$CS_2+O \rightarrow CS+SO \quad (2a)$$

$$\rightarrow COS+S \quad (2b)$$

$$\rightarrow CO+S_2 \quad (2c)$$

and

$$CS_2+h\nu \rightarrow CS+S \qquad \lambda < 2{,}200\ \text{Å} \quad (3a)$$

$$\rightarrow CS_2^* \qquad \lambda > 2{,}200\ \text{Å} \quad (3b)$$

Reaction (1a) is exothermic while reaction (1b) is endothermic[9]. Recent work by Kurylo and Laufer[10] indirectly supports reaction (1a). Reaction (2) dominates in the stratosphere and proceeds[11] primarily through reaction (2a). Photolysis of CS_2 (reaction (3a)) seems to be relatively unimportant according to

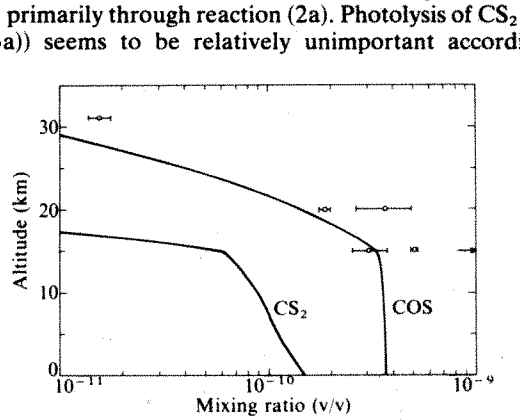

Fig. 1 Computed vertical profiles of CS_2 and COS. The profiles are calculated using a one-dimensional model described previously[20]. The rate constants for O—C—N—Cl—S chemistry are from ref. 29 and the main sulphur reactions are given in Table 1. The diffusion coefficients are from ref. 30. The boundary conditions at 0 km are 0.15 p.p.b. for CS_2 and zero flux for COS. Observed CS_2 and COS surface concentrations range from 0.07 to 0.37 p.p.b. (ref. 7) and 0.3 to 0.5 p.p.b. (refs 7, 21, 22) respectively. The stratospheric COS data[31] (○) are plotted for comparison. The arrow indicates the position of the tropopause.

0028-0836/79/300308—03$01.00
© Macmillan Journals Ltd 1979

absorption cross-section data[12]. Photo-excitation of CS_2 (reaction (3b)) and the subsequent chemistry involving CS_2^* could lead to additional production of COS and SO_2 (refs 13, 14). Reactions involving CS_2^* have not been included in this study due to lack of laboratory data. Reaction (1a) could provide a major source for COS. We assume that reaction products such as HS, CS and S would ultimately be oxidised to form SO_2 over a relatively short time, although reaction of CS with O_2 could provide an additional source for COS (ref. 15). Chemical removal of SO_2 in the stratosphere is dominated[16–18] by the reaction,

$$OH + SO_2 + M \rightarrow HSO_3 + M \qquad (4)$$

The main chemical processes are summarised in Table 1. The rate constants $R1$ and $R5$ (Table 1) used are from Kurylo[9]. These values[9] apparently conflict with the corresponding upper limits set by Atkinson *et al.*[19], whose measurements were performed in less stringent conditions (higher reactant pressure). The observed[19] nonlinear dependence of first-order OH decay rates on reactant concentration may be attributed to complications[9] associated with secondary reactions.

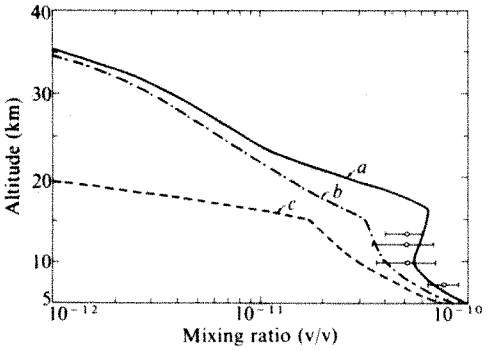

Fig. 2 Computed vertical profiles of SO_2, (lines) and measurements (circles)[5]. Curve *a* is calculated using the full model described in Table 1. Curve *b* is calculated with CS_2 chemistry omitted. Curve *c* is calculated with both COS and CS_2 chemistry omitted. In all three curves, a value of 0.3 p.p.b. is assumed for SO_2 at 1 km. This boundary is chosen such that the integrated tropospheric abundance of SO_2 is equal to 6×10^5 (S) ton, a value consistent with the global estimates of 4.5×10^5 and 5.2×10^5 (S) ton given by Mészáros[32] and Friend[33], respectively. The fixed mixing ratio boundary condition at 1 km implicitly incorporates[28] the effects of any production processes (for example, H_2S oxidation, anthropogenic and volcanic emissions) and removal processes (for example dry deposition) occurring below 1 km. Note that the reported data[5] were taken at ~50° N, while our model corresponds to 30° N. For proper comparison, the data points should be shifted upwards by ~2 km (ref. 30).

The vertical distribution of a minor species may be obtained by solving the appropriate one-dimensional continuity and flux equations[20]. Figure 1 shows the calculated altitude profiles of CS_2 and COS. The calculated mixing ratio of CS_2 drops abruptly above ~14 km altitude, reflecting the onset of the relatively fast reaction of CS_2 and O atoms. In calculating the COS profile, we specify a zero flux surface boundary condition instead of using its mixing ratio at the boundary, an assumption consistent with our premise that CS_2 is a precursor[8] of COS. The apparent agreement between the predicted and observed surface COS mixing ratios[7,21,22] of about 0.4 p.p.b. may be fortuitous in view of the possible ambiguities in rate constant data ($R1$ and $R5$ in Table 1) and paucity of CS_2 data. Nevertheless, an approximate balance in COS budget[8] may be achieved so long as the relationship

$$\frac{[CS_2]}{[COS]} \approx \frac{R5}{R1} \qquad (5)$$

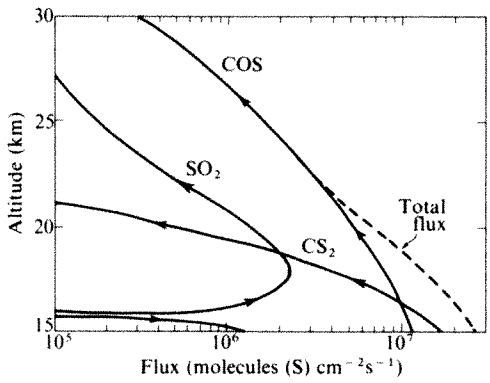

Fig. 3 Computed fluxes for CS_2, COS and SO_2. The flux of CS_2 has been multiplied by 2, reflecting that each molecule carries two sulphur atoms. The total flux Φ_t is set equal to $2\phi_{CS_2} + \phi_{COS} + \phi_{SO_2}$. The arrows indicate direction of flow.

holds in the lower troposphere. Otherwise, alternative sources and/or sinks for COS must be found to account for the observed surface concentrations of COS. If $R1$ were much less than the value[9] used here, CS_2 would remain relatively well mixed in the troposphere, making it a more potent source of stratospheric SO_2.

Figure 2 shows the altitude profiles of SO_2 and data reported by Jaeschke[5]. These three curves correspond to different assumptions concerning the atmospheric sources of SO_2. Curve *c* illustrates the case where there is no *in situ* source for SO_2. The rapid decrease in mixing ratio reflects the rapid removal of SO_2 by reaction (4). Curve *a* (standard model) represents the full model calculation where SO_2 is produced locally by reactions $R1$ through $R6$ in Table 1. Our calculation showed that SO_2 (curve *a*) is relatively well mixed in the region 10–15 km, agreeing with observed data[5], although such a feature could be accounted for by upwelling air motion during particular weather conditions of the day[5]. Note that in the absence of a CS_2 source, the calculated SO_2 distribution (curve *b*) lies somewhat below the observed data[5].

Figure 3 shows the combined flux, Φ_t, of CS_2, COS and SO_2 of about 2.5×10^7 molecules (S) $cm^{-2}\,s^{-1}$ or 2.1×10^5 ton (S) yr^{-1} into the stratosphere. This value should be compared with several independent estimates[3,23,24] of 5×10^6 to 2×10^7 molecules (S) $cm^{-2}\,s^{-1}$ necessary to sustain the sulphate layer. Note that the major contribution to Φ_t comes from CS_2 and COS, with each gas dominating at different altitude regions. The rapid increase of SO_2 flux with altitude between 15 and 17 km reflects the *in situ* production of SO_2 in the model rather than upward diffusion[3] of SO_2 from the troposphere. It seems that the persistence of the sulphate layer may be attributed partly to the oxidation of CS_2 below ~20 km and partly to the oxidation of COS above ~20 km, and that the observed altitude[3,23] (≈20 km) at which the sulphate layer peaks may be modulated by the relative strengths as well as the altitude dependence of these two sources.

The calculated global flux of CS_2 is about 6.4×10^8 molecules (S) $cm^{-2}\,s^{-1}$ or 5.4×10^6 ton (S) yr^{-1}, implying a CS_2 life time of about 0.2 yr compared with that of COS of about 0.6 yr. The calculated flux depends on the tropospheric OH concentration, CS_2 boundary condition and rate constant $R1$, all of which are subject to large uncertainties. The measured concentration of CS_2 in seawater samples reported by Lovelock[6] suggests that the ocean might provide a source of CS_2 of order 10^7 molecules (S) $cm^{-2}\,s^{-1}$ based on a simple piston model[25]. The role of the ocean in the atmospheric CS_2 budget has yet to be determined.

In conclusion, CS_2 could have an important role in the stratospheric sulphur budget. Clearly, more atmospheric measurements of SO_2, CS_2 and COS, as well as accurate determination of rate constants for $R1$ and $R5$, are needed for model validation. It is also evident that other sources of CS_2 and COS need to be identified.

We thank M. Kurylo for discussions. This work is partially supported by the Air Force Geophysics Laboratory under contract F19268-78-C-0215 and by the Manufacturing Chemists Association.

Thermohaline intrusions lie across isopycnals

A MAJOR task of physical oceanography is the determination of the fluxes of heat and salt and the identification of the processes responsible for producing the fluxes. For the development of realistic models of the ocean it is particularly important that fluxes across surfaces of constant density (isopycnal surfaces) be distinguished from those along isopycnals. We report here direct evidence that at least some of the 5–20-m thick intrusions commonly found in regions of strong horizontal variability (fronts) lie across isopycnals. The intrusions are formed by primarily lateral advection to produce complicated interleavings of the differing types of water across the fronts. The ubiquitous occurrence of intrusions in frontal regions and the fact that they cross isopycnal surfaces indicates that they are important factors in the vertical, as well as the horizontal, flux budgets of heat and salt. The low levels of cross-isopycnal fluxes due to small scale turbulence away from fronts[1] further suggests that these intrusions may be important in the overall global flux budgets of heat and salt.

The intrusions were studied at Ocean Station P (50° N, 145° W) in August 1977 during the mixed layer experiment (MILE). One of the reasons for selecting the site was its distance from known fronts. However, repeated surveys with a rapidly profiling towed vehicle revealed fronts in the weakly stratified region between 40 m (the base of the seasonal thermocline) and 100 m (the beginning of a strong salinity increase or halocline). The fronts were characterised by lateral changes along isopycnal-surfaces of 0.4 °C and 0.05% over distances <2 km.

Tongues of water up to 8 km long, with widths of 1 km and thicknesses of 10–20 m, were observed to intrude into the warmer, more saline water from the cool, low salinity side of one of the fronts. Figure 1 shows the down profiles from a tow section across a tongue. The section was roughly parallel to the front so the section shows the tongue in the direction of its minimum horizontal extent. Minima in temperature and salinity appear in the 7th profile between 0.5 and 0.55 MPa (these pressures correspond to nearly 50 m in depth) and slope downwards towards the right. The structure also becomes thicker as it deepens and shows splitting into double minima. The density changes due to the matched temperature and salinity structures are so nearly compensating that little evidence for the feature is apparent in the bottom set of profiles.

To be certain that the slope is not due to a changing internal wave displacement, the temperature and salinity contours must be examined as functions of potential density rather than of pressure. The quality of the density profiles is central to this argument. Careful laboratory tests of the temperature and conductivity sensors[2,3] show that the r.m.s. random noise in the data is equivalent to 2.1×10^{-4} kg m^{-3}, which is negligible for our purpose. The dynamic response of the temperature probe as it passed through a thin plume was obtained in the laboratory. The response of the conductivity cell, determined by comparison of the temperature–salinity diagrams from up and down depth cycles, showed that the cell response was closely matched to that of temperature. Even so, a numerical simulation of the sensors passing through features similar to those in Fig. 1 revealed that density errors equivalent to displacements of 1–3 m could occur as a consequence of microstructure in the profile. However, this is much less than the 15 m vertical displacement of feature across the tow path.

Contours of isotherms plotted in Fig. 2 with potential density as the vertical coordinate show the temperature minimum sloping with respect to lines of constant density. This figure includes data preceding that in Fig. 1, showing the nearly level isotherms in a region where an intrusion is not present. As a further test of the data, additional contours were made using only the up traces. If the slope were an artefact of a dynamic response

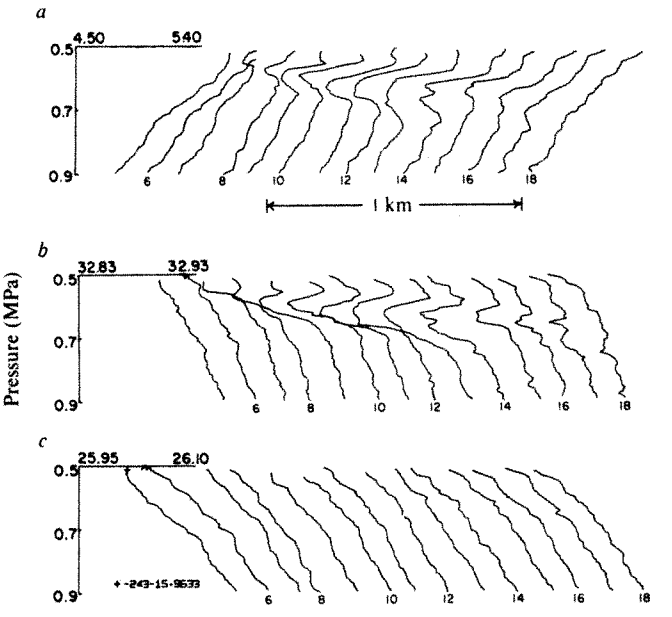

Fig. 1 Successive down profiles of temperature (*a*), salinity (*b*) and density (*c*) from a depth-cycling towed vehicle (1 MPa corresponds to a depth interval of 99.2 m). Pronounced minima in temperature and salinity slope downward from left to right and mark an intrusion of cool, low salinity water into the profile. The density effects of the cooler (an increase in density), low salinity (a decrease in density) water are so nearly compensating that there is little evidence for the feature in the bottom set of profiles.

problem, the slope should have reversed in the up casts. This is not the case and the maps are nearly identical to Fig. 2.

A section made at a 60° angle to that shown in the figures showed that the intrusion was also sloping downwards across isopycnal surfaces in a direction away from the front. Microstructure profiles through similar intrusions[5] have revealed distinctive signatures on the upper and lower boundaries of the minima that have been identified as the appropriate type of double-diffusive convection.

Double-diffusive convection is a consequence of the much lower molecular diffusivity of salt dissolved in water compared to the thermal diffusivity[6]. Consequently, when warm, saline water overlies cool, fresh water in a stratified profile small perturbations lead to a series of centimetre thick rising and descending columns known as salt fingers. When warm, saline water occurs beneath cooler, fresher water (known as the diffusive regime), a sequence of convecting regions separated by their interfaces is formed. Although the observations in Fig. 1 did not have the spatial resolution to detect the signatures of double diffusion, the inference from the microstructure observations is that salt fingering occurred above the minima and the diffusive regime below. Laboratory experiments[7] of diffusively unstable intrusions have shown that the increase in density below a salt fingering region dominates the decrease above the 'diffusive' regime, with the consequence that cool, fresh intrusions tend to sink as they move laterally. The thickening and formation multiple minima are also revealed in the laboratory work.

The cross-isopycnal slope of 100 m-thick intrusions across the Antarctic Front has been inferred[7] by a cross-spectral comparison of horizontally separated profiles. We have obtained the same result directly for much thinner features by mapping against density.

Connectance in real biotic communities and critical values for stability of model ecosystems

BIOLOGICAL communities differ in the number of species that they contain; in the number of interactions between species (primarily feeding and competitive relationships); and in the intensity of their interactions. We present here the first extensive empirical data on the relationship between connectance (defined as the fraction of the pairs of species which directly interact[1,2]) and species richness in biological communities. Our results show that connectance may decline considerably as the number of species increases.

A decade ago, most ecologists firmly believed that increased ecosystem complexity (both the number of species and the number of interactions) would lead to greater ecosystem stability. For example, Odum[3] suggested that "Higher diversity, then, means longer food chains and more cases of symbiosis (mutualism, parasitism, commensalism, and so forth), and greater possibilities for negative feedback control, which reduces oscillations and hence increases stability". This attractive and widespread statement has been shaken dramatically by May[1,2,4,5] and his followers[6-13]. May examined the complexity–stability question in model ecosystems by constructing interaction matrices with each off-diagonal element (interaction coefficient) assigned from a distribution of random numbers, where distribution itself has mean value zero, and standard deviation value (interaction strength) s; the stability of the matrices was then evaluated in terms of their eigenvalues[14]. The central feature of May's results for model ecosystems is the sharp transition from stable to unstable behaviour as soon as either the species number m, or the connectance C, or the interaction strength s, exceeds a critical value. If the equation $s\sqrt{mC} > 1$ holds, the system will almost certainly be unstable. In general, by becoming more complex a system becomes less likely to be stable. Selected empirical evidence supports such a conclusion. According to May[4], "this inverts the naive, if well-intentioned, view that 'complexity begets stability', and its accompanying moral that we should preserve, or even create, complex systems as buffers against man's importunities". May's corollaries are useful for sharpening discussion but their application to natural resource management and optimum land use is not without danger.

Recently, Lawlor[15] has shown that severe constraints must be introduced on the structure of an interaction matrix if it is to represent a biologically acceptable system. He has suggested, *inter alia*, the hyperbolic reduction of the connectance C as the number of species m increases: $Cm = 10$. This relationship ensures stability if the standard deviation s of the interaction coefficients (not variance; this is the mistake of Lawlor), is less than about one-third. Lawlor's comments induce the urgent question: What is the true connectance of real communities?

The question seems to be unanswerable on the basis of very rough, speculative or fragmentary data in most of the literature, even if such data are sometimes used in theoretical considerations. The extensive data collected by one of us[16,17] have allowed reconstitution of the food webs in a great number of plant–aphid–parasitoid communities. The parasitoids belong to three families: Aphidiidae, Aphelinidae and Encyrtidae (Hymenoptera). All host–parasitoid relationships have been tested in the laboratory. The results for one representative community are demonstrated in Fig. 1. In the cannopy of an oak–pine–birch forest (the order Pino–Quercetalia Soó 1962 in the sense of the Zürich–Montpellier phytosociological school) 37 species have been recorded of vascular plants, aphids and their parasitoids; a trophic connectance of 0.059 has been calculated for this community. Some chains have been confirmed by numerous field assessments, for example, 23 geographically distinct observations for that of *Pinus silvestris–Schizolachnus pineti–Pauesia*

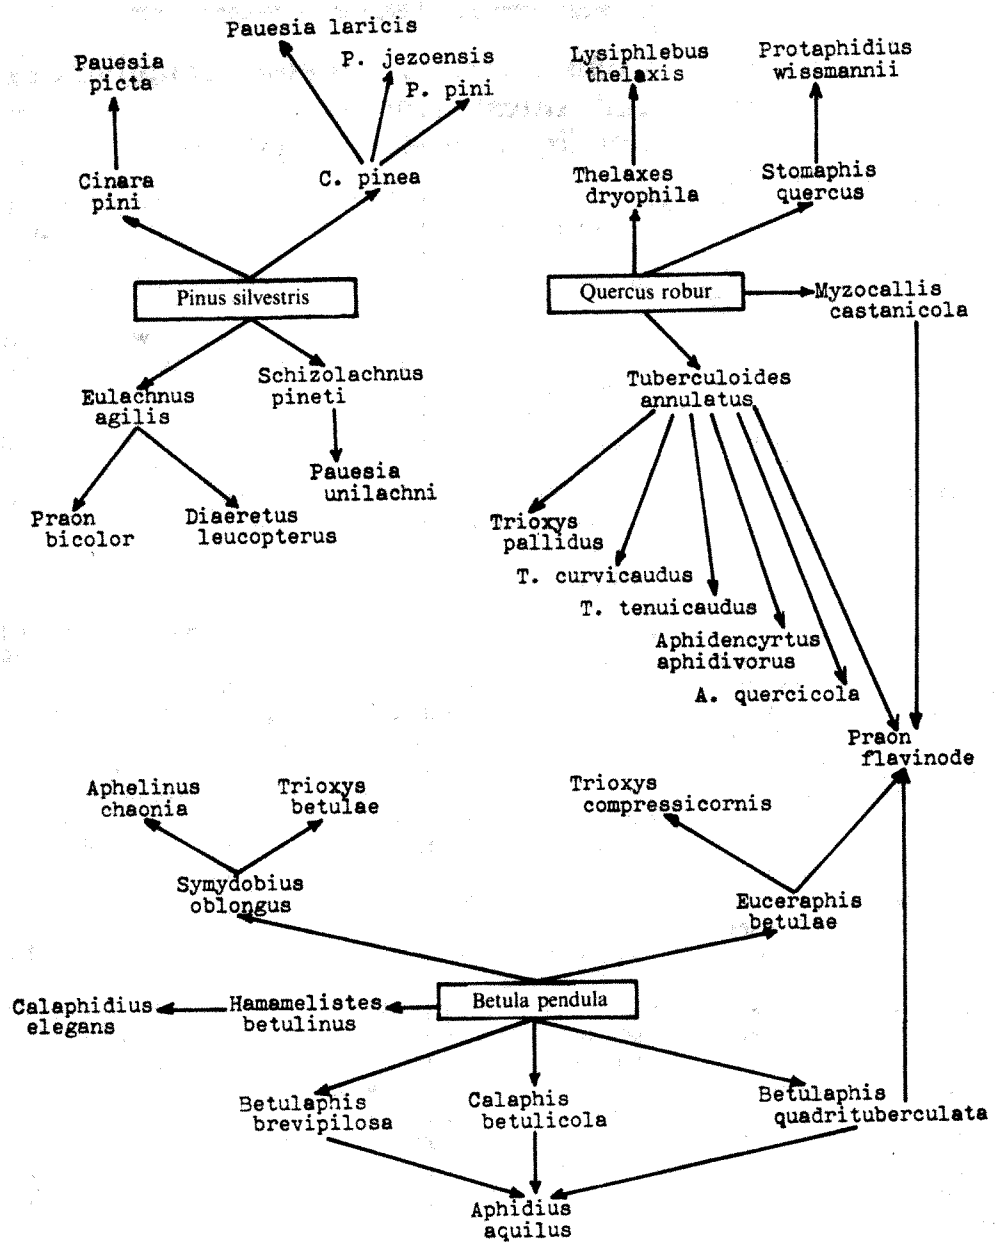

Fig. 1 An example of the plant–aphid–parasitoid food web: a cannopy of oak–pine–birch forest in Central Europe (number of species = 37, trophic connectance = 0.059, potential total connectance = 0.137).

unilachni. Other chains are not so remarkable, for example, that of *Betula pendula–Betulaphis brevipilosa–Aphidius aquilus*. The potential total connectance is highly overestimated because it has been calculated on the basis of both the discovered trophic connections and all potential competitive interactions derived from the structure of the food webs regardless of the biological reality. The aggregation of the populations[18] and the differentiation of the food niches considerably reduce the number of competitive interactions. For example, *Cinara pinea* can never directly compete with *Eulachnus agilis* or *Schizolachnus pineti* despite the common plant host.

Food webs have been reconstructed for 31 plant–aphid–parasitoid communities; the summary of the connectance analysis is presented in Fig. 2. The analysed communities cover a broad variety of Central European biotopes and successional stages. With regard to the previous comments, we may conclude that the decrease in total connectance with increased species richness fits very closely the relationship $Cm = 3$. This reduced connectance ensures the stability of model ecosystems if the standard deviation s of the interaction coefficients is less than 0.577, that is, the variance is less than one-third. It means that with this modest value of s, an increasing number of species does not cause a decrease of model stability: a conclusion which, at

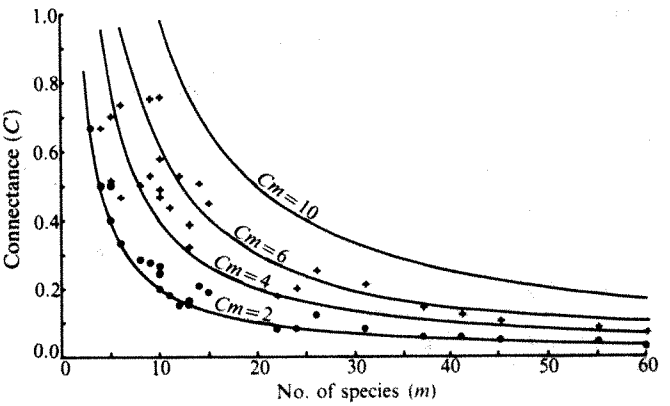

Fig. 2 Four hyperbolic approximations and the empirical relationships between connectance (c) and species number (m) in real plant–aphid–parasitoid communities. Potential total C (+) was calculated on the basis of both the discovered trophic connectance (●) ions and all potential competitive interactions derived from the structure of the food webs (see, for example, Fig. 1) regardless of the biological reality.

least, does not contradict the traditional ecological hypothesis. Connectance values for pure competition communities have recently been estimated by McNaughton[19]. His data for communities consisting of up to 20 plant species follow roughly the product $Cm = 4.7$.

The low connectance assessed by us in plant–aphid–parasitoid communities, arises undoubtedly from their organisation in guilds of species interacting within each guild, whereas their interactions with species in other guilds are only loose. Such an organisation may reduce the destabilising effect of greater system complexity[1,2]. It seems likely that the majority of the plant–aphid–parasitoid communities possesses structures which correspond to the boundary conditions of model stability. This is, of course, a rather speculative conclusion as we are unable to estimate the s values. On the other hand, there is no evidence for the existence of any plant–aphid–parasitoid communities outside the region $2 < Cm < 6$. Destabilising effects can be expected, through increased connectance caused by hyperparasitoids and predators, both with broader food spectra[20,21]; further study is required on this point.

Abnormal visual resolution of cats reared in stroboscopic illumination

REARING animals in a visually restricted environment can lead to marked abnormalities of both the response properties of single visual neurones[1–4] and the visual capacities of the organism[5,6]. These findings have important implications for understanding the development of human vision and have led to many studies of visually deprived humans[7–9]. Although there are similarities between the effects of deprivation in animals and humans there are still major difficulties in extrapolating from experimental deprivation to clinically observed amblyopia. There is, therefore, a need for quantitative psychophysical studies of visually deprived animals using the same tests as those used with human patients. We have quantified the pattern vision of visually deprived cats by measuring their spatial contrast sensitivity, an approach which has frequently been used to characterise the vision of human amblyopes[7–9]. We report here that the spatial resolution of cats reared in stroboscopic illumination is seriously impaired and that changes in their contrast sensitivity are similar to those seen in certain types of amblyopia.

Stroboscopic illumination prevents the perception of motion while allowing rather restricted pattern vision. Animals reared in this illumination show greatly reduced directional selectivity and binocularity of visual neurones in the superior colliculus and visual cortex[10,11], impaired orientation tuning in cortical neurones[11], and marked difficulties in visually guided behaviour[12,13]. However, there is as yet no quantitative description of their visual capacities.

Six cats were used. Three were reared from birth in a room illuminated by a 3-μs strobe light, flashed at a frequency of 40 min^{-1} for 12 h per day. One control cat was reared in a long duration (750 ms) flash of the same frequency as the strobe light. This 750-ms flash permitted the perception of motion while providing a control for the periodicity and low luminance of the strobe environment. The effective luminance of these two types of illumination was equated using a behavioural test in which luminance thresholds for grating discrimination were determined in normal cats for each of these light sources (T.P. and W.H.M., in preparation). When the deprived cats were at least a year old they were removed from the visually restricted environment. Testing began after at least 2 months of adaptation to normal illumination. Two more cats were obtained from a supplier and presumably had normal visual experience during development.

Our behavioural testing techniques resembled those developed by Berkley[14]. The cats were trained to discriminate between a vertical grating of sinusoidal horizontal luminance profile and a uniform field, each at a mean luminance of 15.9 cd m^{-2}. They responded by pressing with their nose on one of two transparent response panels through which the stimuli were visible. The stimuli were 30 cm behind the response panels, subtended a visual angle of $16° \times 20°$, and were generated on display oscilloscopes by conventional techniques[15].

On each trial the stimulus was present for 2 s before the response panel could be activated. Correct responses were rewarded with beef purée and the next trial began 5 s later. Following incorrect responses, no food reward was delivered and the start of the inter-trial interval was delayed 10 s. The position of the correct stimulus varied randomly.

Once the cats mastered the task (4 consecutive days ≥80% correct, 200 trials a day), measurement of contrast thresholds over a range of spatial frequencies began. Performance at a single spatial frequency was tested during each daily session of 200 trials. We used the method of constant stimuli to generate a psychometric function in each session: five contrast levels chosen to bracket the threshold were presented in random order within each block of five trials. Contrast threshold was defined from the resulting psychometric function as the contrast corresponding to 75% correct.

The results are shown in Fig. 1*a*. At the frequency of peak sensitivity, normal cats and the 750-ms control cat can resolve gratings of ~1.4% contrast. Their sensitivity decreases at lower and higher spatial frequencies. The functions for the three strobe cats show greatly reduced sensitivity at all spatial frequencies and a peak shifted towards lower frequencies. The minimal resolvable contrast for the three cats ranged from 7.6 to 29%. Strobe cats also showed a reduction of about 1.5 octaves in the high-frequency cut-off. Figure 1*b* shows log sensitivity loss for the three strobe cats, relative to the 750-ms control. This plot clearly demonstrates increasing sensitivity loss with higher spatial frequencies.

The functions in Fig. 1*a* have shown little change over more than 2 years of testing despite continuing exposure of the cats to a normal laboratory environment. Thus, these deficits are relatively permanent. It is unlikely, moreover, that optical factors can account for these losses. We tested all cats at a distance of 30 cm, which is close to the near point of accommodation for

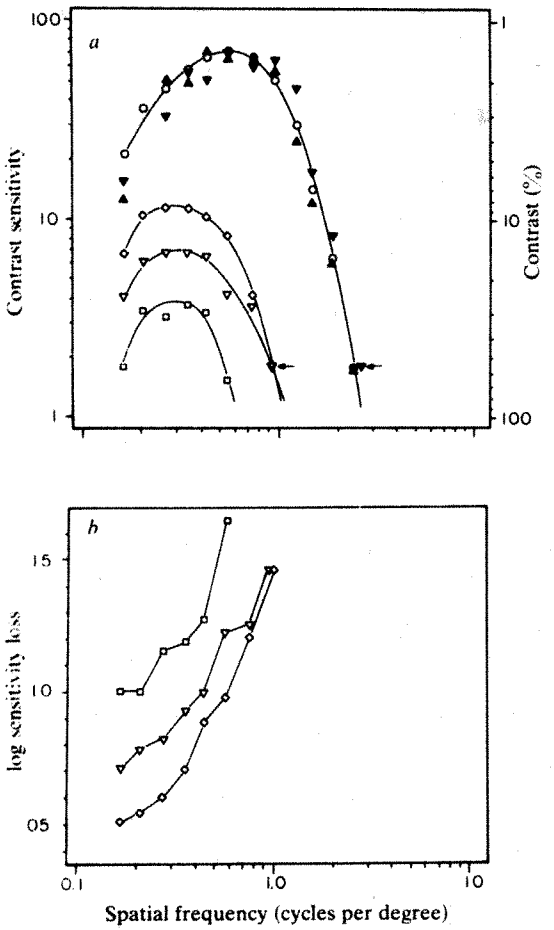

Fig. 1 *a*. Contrast sensitivity (reciprocal of threshold contrast which is shown on the right ordinate) as a function of spatial frequency. ○, 750-ms Control cat; △, □, ◇, three strobe-reared cats. Individual curves were fitted by eye. ▲, ▼, The two normal cats. Points indicated by the arrows are acuity measurements obtained by presenting a range of spatial frequencies at 55% contrast. Each point represents the reciprocal of the contrast value corresponding to 75% correct performance at that frequency and is based on at least 400 trials. Luminance, 15.9 cd m^{-2}; viewing distance, 30 cm; field size, 20° × 16°. *b*, Sensitivity loss for the three strobe-reared cats compared to the 750-ms control cat as a function of spatial frequency. The same symbol is used for each cat as in *a*. Each point represents the ratio of sensitivity of the 750-ms control cat to the sensitivity of the strobe-reared cat expressed in log units. 0.0 corresponds to no loss, 1.0 to a 10-fold reduction in sensitivity.

cats[16]. Refraction by split lamp retinoscopy showed our strobe cats to be slightly myopic (−0.5 to −1.5 dioptre), thus if their accommodative power was normal, they should have been able to focus at that distance. Moreover, optical blurring primarily degrades the resolution of high spatial frequencies[7] and could not account for the losses we observed at low frequencies. Therefore, we suggest that these deficits have a neural basis. Abnormalities in area 17, which have been reported in strobe-reared cats[11], could reduce behavioural contrast sensitivity as striate neurones are particularly sensitive to high spatial frequencies and have low contrast thresholds[17].

The profound visual loss of strobe-reared cats indicates that stroboscopic illumination, which has been used to examine the effects of motion deprivation, also severely restricts spatial vision. However, the normal contrast sensitivity of the cat reared in the long-duration flash demonstrates that the visual loss of strobe-reared cats is not due to either the low time-averaged luminance or periodicity of the strobe illumination. The pattern of visual loss, with the greatest impairment at high spatial frequencies, is similar to that found in strabismic[8,18] and anisometropic[8] amblyopia, suggesting common features between the visual environments of strobe-reared cats and human amblyopes. The visual deficit in these types of amblyopia has been attributed to the consistently blurred image in the amblyopic eye, which has its greatest impact on the visibility of high spatial frequencies. Optical blur may also be an important factor in strobe rearing as the extremely short-flash duration precludes normal accommodation, thus limiting the visibility of high spatial frequencies.

A greater loss at high than at low spatial frequencies in human amblyopes is commonly attributed to a selective impairment of sustained visual neurones[8,9], which, in contrast to transient neurones, respond better to higher spatial frequencies but prefer slower rates of temporal modulation[19]. The contrast sensitivity data reported here as well as the recent finding of reduced sensitivity to slow motion in strobe-reared cats[20] suggests that the major impact of strobe rearing is also on the sustained neurones. Consistent with this interpretation is the observation that sustained neurones are especially dependent on proper accommodation[21] and that they project exclusively to area 17 (ref. 22), which is highly abnormal in strobe-reared animals. Future measurements of the contrast sensitivity of cortical neurones in these cats will help clarify the relationship between neural and perceptual abnormalities in strobe rearing and may provide important insights into neural mechanisms involved in high spatial frequency loss.

An intrinsic factor XII–prekallikrein-dependent pathway activates the human plasma renin–angiotensin system

EXPOSURE of normal human plasma to an activating (negatively charged) surface leads to the activation of the intrinsic coagulation system and the fibrinolytic system and the generation of vasoactive peptides (kinins)[1,2]. This contact activation mechanism is known to be initiated by factor XII (Hageman factor). Surface-activated factor XII converts prekallikrein (Fletcher factor) into kallikrein, which leads to further activation of factor XII. Prekallikrein circulates in plasma as a complex with the kallikrein substrate, high molecular weight kininogen, and the latter acts as a cofactor in the reciprocal activation of factor XII by kallikrein. The experiments described here demonstrate that the renin–angiotensin system is also activated by kallikrein through the factor XII-dependent pathway.

Normally, about 80% of the renin present in plasma is in an enzymatically inactive form[3–5]. It is called 'inactive renin' or 'prorenin', as opposed to naturally occurring 'active renin'. Both forms can be separated by ion-exchange chromatography[6]. Inactive renin is converted into the active form by limited proteolysis at neutral *p*H, either in acid-pretreated plasma by one or more endogenous serine proteases[7–9] and by urinary (renal) kallikrein[10], or in untreated plasma with exogenous trypsin[5,9]. Active renin is also formed during prolonged exposure of plasma to low temperature (cryoactivation)[11]. Recent reports have suggested that factor XII and prekallikrein might be involved in the generation of active renin, but the results were contradictory[12,13]. To investigate the possible involvement of the factor XII-dependent pathway in the activation of prorenin, we treated normal plasma ($n = 10$), factor XII-deficient plasma ($n = 2$) and prekallikrein-deficient plasma ($n = 1$) by (1) dialysis at *p*H 3.3 and 4 °C for 24 h with subsequent restoration of *p*H to 7.5 (ref. 14), or (2) incubation with Sepharose-bound trypsin at *p*H 7.5 and 4 °C. Renin was then measured by radioimmunoassay of angiotensin I formed after incubation of the plasma samples with an excess of purified sheep renin substrate at *p*H 7.5 and 37 °C for 3 h (ref. 4). Results in normal plasma showed identical amounts of activated renin after acid or trypsin treatment (Fig. 1, left-hand scale). Smaller increments of active renin were obtained during cryoactivation. In plasma from patients with Hageman trait, levels of naturally occurring active renin were 17 and 21 $\mu U\ ml^{-1}$, and those of inactive (trypsin-activable) renin 180 and 210 $\mu U\ ml^{-1}$. These values were within the normal range found in our laboratory, which is 12–45 $\mu U\ ml^{-1}$ for active renin and 70–230 $\mu U\ ml^{-1}$ for inactive renin ($n = 25$). In samples from the patient with Fletcher trait, active renin was low, 8.4 $\mu U\ ml^{-1}$, but inactive renin was markedly elevated, 510 $\mu U\ ml^{-1}$. In contrast to normal plasma, both factor XII- and prekallikrein-deficient plasma generated small amounts of active renin after acidification, whereas trypsin generated normal or increased amounts. There was no detectable cryoactivation of renin in the deficient plasmas. This suggested that acid activation and cryoactivation of plasma renin depend on the presence of both factor XII and prekallikrein.

Further experiments substantiated this hypothesis. Reconstitution of factor XII-deficient plasma and prekallikrein-deficient plasma with, respectively, purified factor XII and prekallikrein resulted in a correction of the generation of active renin after acidification. Prekallikrein in normal plasma is converted into active kallikrein after exposure of the plasma to low *p*H, trypsin or low temperature (cryoactivation)[15]. Simultaneous determinations of renin and kallikrein measured as amidolytic activity[16] showed parallel increments of both activities (Fig. 1, right-hand scale).

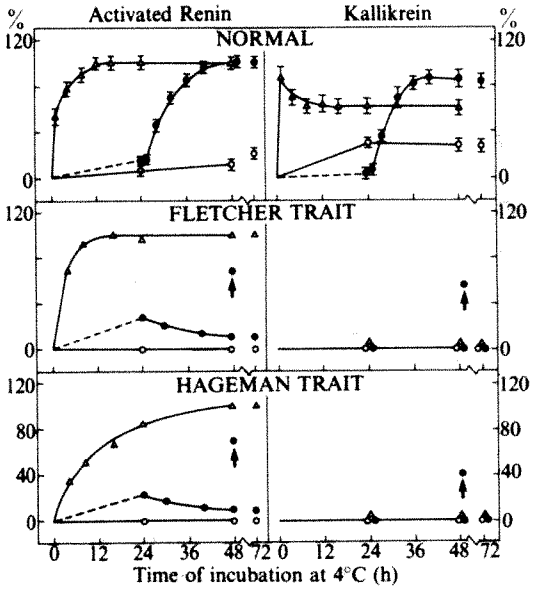

Fig. 1 Generation of active renin and kallikrein in normal plasma (mean ± s.e.m., $n = 10$), prekallikrein (Fletcher factor)-deficient plasma and factor XII (Hageman factor)-deficient plasma. Two procedures were used: acidification and addition of trypsin. Plasma, which contained 5×10^{-3} M EDTA, was acidified (- - - -) by dialysis against 0.15 M glycine-HCl buffer of *p*H 3.3 for 24 h (ref. 14). The *p*H was then restored to 7.5 with 1 M NaOH, and the generation of active renin and kallikrein was followed for 1–72 h (●—●). Trypsin (14,000 BAEE units per mg protein, Sigma) was covalently bound to CNBr-activated Sepharose (Pharmacia) in a ratio of 10 mg protein per g dry Sepharose. The immobilised enzyme was added to plasma (△—△) at a final concentration of 3,000 BAEE units per ml. After 1–48 h it was removed by centrifugation. All these procedures were carried out at 4 °C. Plasma that was kept at 4 °C without any other form of treatment served as a control (○—○). Pretreated and control plasma samples were then assayed for renin and kallikrein activity. For renin measurements the samples were incubated with purified sheep renin substrate (final concentration $6.7 \times K_m$)[4] at *p*H 7.5 and 37 °C for 3 h in the presence of the following protease (angiotensinase) inhibitors: 1×10^{-3} M EDTA, 1×10^{-3} M phenylmethylsulphonylfluoride, 3.4×10^{-3} M 8-hydroxyquinoline and aprotinin (Bayer) at a concentration of 100 kallikrein-inhibiting units per ml of incubate. The increment of renin after 48 h exposure to trypsin was taken as 100% activation. Kallikrein was measured as amidolytic activity using the chromogenic ester H-D-Pro-Phe-Arg-*p*-nitroanilide (PPAN, Kabi) as a substrate[16]. Plasma (15 μl) was mixed at 37 °C with 815 μl Tris buffer of *p*H 7.5 and 200 μl 4.1×10^{-3} M PPAN. The linear release of *p*-nitroanilide was followed at 405 nm for 1–2 min in a 1-cm semi-microcuvette at 37 °C. Complete activation of prekallikrein was obtained by mixing 100 μl of the untreated plasma with 100 μl dextran sulphate ($25\ mg\ l^{-1}$)[18]. After 7 min incubation at 4 °C, 30 μl of the mixture was added to 800 μl Tris buffer and 200 μl PPAN, and kallikrein was measured as before. The values obtained after dialysis at *p*H 3.3 and restoration of *p*H to 7.5 and with trypsin were expressed as a percentage of total activable prekallikrein as obtained with dextran sulphate. Lineweaver–Burk plots for the reactions of acid-activated renin, trypsin-activated renin and naturally occurring active renin with sheep renin substrate (1 h incubation) gave identical K_m values ($\sim 6 \times 10^{-7}\ mol\ l^{-1}$). Thus, the increase of renin activity after acidification and with trypsin is caused by a parallel change in the number of molecules of active renin rather than by changes in the enzymatic activity per molecule of active renin. When untreated normal plasma was kept at 4 °C, small increments in renin and kallikrein activity were observed ($P < 0.001$ for difference of values at 72 h from those at 0 h). Prekallikrein and factor XII were isolated from normal human plasma and purified[19]. They were added to, respectively, prekallikrein-deficient plasma (final concentration of prekallikrein ~ $50\ \mu g\ ml^{-1}$) and factor XII-deficient plasma (final concentration of factor XII ~ $28\ \mu g\ ml^{-1}$). Deficient plasmas to which Tris buffer of *p*H 7.5 was added, instead of prekallikrein or factor XII, served as controls. The reconstituted plasmas and controls were treated by dialysis at *p*H 3.3 for 24 h, and the renin and kallikrein activities were measured 24 h after the *p*H had been restored to 7.5 (results are indicated by arrows).

The acid activation of prekallikrein was confirmed by the parallel cleavage of ^{125}I-labelled prekallikrein added to normal plasma before acidification (Fig. 2). Previous experiments in which the activation of prekallikrein by activated factor XII was studied had shown that the generation of kallikrein activity was directly correlated with the extent of proteolytic cleavage[17]. Analysis of the reaction mixture by SDS-polyacrylamide gel electrophoresis in the presence of reducing agents demonstrated that the disappearance of prekallikrein of apparent molecular

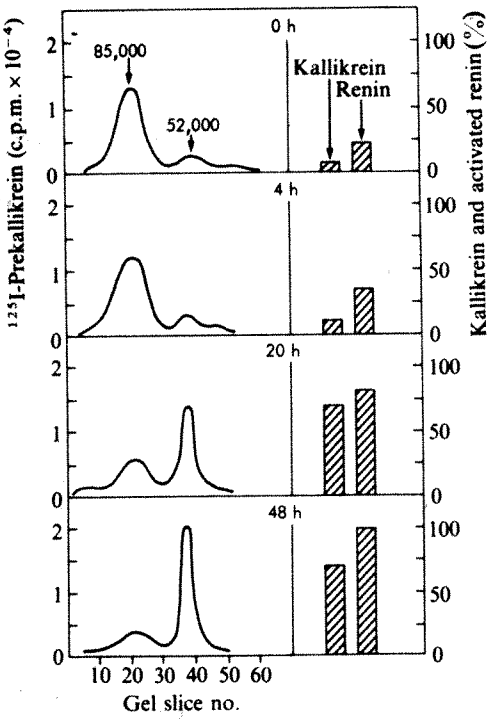

Fig. 2 Cleavage of ^{125}I-prekallikrein in acid-pretreated normal plasma. Prekallikrein was isolated from normal plasma[19] and labelled by the method of Bolton and Hunter[20]. ^{125}I-prekallikrein (~2.7 μCi in 15 μl) was added to 600 μl normal plasma. The mixture was dialysed at *p*H 3.3 for 24 h. Immediately (0 h) after restoration of *p*H to 7.5 with 1 M NaOH, and 4–48 h later, the reaction mixtures were analysed for the presence of cleavage products of ^{125}I-prekallikrein (left) and for kallikrein and renin activity (right). After reduction by β-mercaptoethanol the reaction mixture was subjected to SDS-polyacrylamide gel (7.5%) electrophoresis. The gels were sliced and the radioactivity in each slice (1.2 mm) was counted. The appearance of cleavage products with an apparent molecular weight of 52,000 indicates activation of prekallikrein[17].

weight 85,000 was associated with the simultaneous generation of cleavage fragments; the major radiolabelled fragment had an apparent molecular weight of 52,000.

Addition of a physiological amount of purified plasma kallikrein to factor XII-deficient plasma after the acidification step, caused complete activation of inactive renin (Fig. 3).

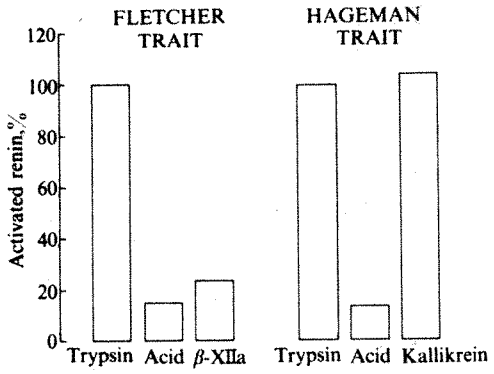

Fig. 3 Generation of active renin in prekallikrein (Fletcher factor)-deficient plasma and factor XII (Hageman factor)-deficient plasma. Plasma was treated with Sepharose-bound trypsin at *p*H 7.5 and 4 °C for 48 h or was dialysed at *p*H 3.3 for 24 h followed by dialysis at *p*H 7.5 and, 4 °C for 24 h. Factor β-XIIa (final concentration 10 μg ml^{-1}) was added to prekallikrein-deficient plasma after 24 h dialysis of the plasma at *p*H 3.3 and restoration of *p*H to 7.5. Plasma kallikrein (final concentration 32 μg ml^{-1}) was added to factor XII-deficient plasma again after 24 h dialysis of the plasma at *p*H 3.3 and restoration of *p*H to 7.5. The mixtures were incubated at 4 °C for 24 h. Factor β-XIIa (600 μg ml^{-1}) (from Dr John Griffin) gave a single band on SDS-polyacrylamide gel electrophoresis with an apparent MW of 28,000. Kallikrein (200 μg ml^{-1}) was prepared by activation of plasma prekallikrein by factor β-XIIa and was separated from factor β-XIIa by DEAE-Sephadex chromatography at *p*H 8.25[19].

Active factor XII fragment (β-XIIa) in a physiological concentration, however, was not capable of generating active renin in prekallikrein-deficient plasma. This indicates that in the factor XII-dependent pathway, plasma kallikrein is the major activator of inactive renin. The factor XII-dependency can be explained by the capacity of this factor to convert plasma prekallikrein into kallikrein.

We conclude that factor XII and prekallikrein are part of an endogenous pathway that activates renin *in vitro*. It is of interest that inactive (trypsin-activable) plasma renin was grossly elevated in the patient with Fletcher trait, whereas his plasma level of naturally occurring active renin was abnormally low. This may indicate that the factor XII–prekallikrein pathway is also important for the activation of renin *in vivo*. Possibly, inactive renin that is adsorbed or bound to the blood vessel wall, at sites that are inaccessible to circulating protease inhibitors, is activated through this pathway. The reported activation of prorenin after the addition of renal kallikrein to acid-pretreated plasma[10] suggests a further analogy with the clotting and fibrinolytic systems: plasma kallikrein is part of an intrinsic pathway for activating the renin–angiotensin system, whereas tissue (renal) kallikrein might be involved in extrinsic activation.

Macrophage requirements for mouse B-cell stimulation differ according to the molecular form of anti-IgM antibodies

THYMUS-INDEPENDENT lymphocytes (B cells) comprise a heterogeneous population. Because of this heterogeneity, the precise nature of the signals which activate resting B cells to become antibody-forming cells is not known. It is likely that different subsets of B cells have different signalling requirements[1–3]. In addition, it has been proposed that B-cell proliferation and differentiation are controlled by separate and distinct signals[4]. Proliferation is thought to result from antigen binding with specific cell-surface immunoglobulin (Ig) receptors. However, due to the very low frequency of B cells reactive to a specific antigen, the activation process *per se* is difficult to study. This problem may be overcome by using reagents which mimic specific antigen binding to Ig receptors but act as poly-

Unseparated or macrophage-depleted spleen cells from 8-month-old CBA mice were cultured in triplicate for 3 d in flat-bottom microtitre plates at 4×10^5 cells per well. The cells were stimulated by addition of optimal doses of rabbit anti-IgM, $F(ab')_2$ anti-IgM or *Eschericha coli* 011B4 LPS. Control cultures received normal rabbit globulin (NRG), $F(ab')_2$ NRG or medium. Normal peritoneal macrophages were collected by lavage from CBA mice and added to macrophage-depleted cultures as indicated. All cultures were pulsed with 0.5 μCi of ^{3}H-thymidine for the last 24 h of culture. ^{3}H-thymidine incorporation is expressed as mean c.p.m. of triplicate cultures ± s.e.m.

* Macrophage-depleted spleen cells contained < 1% macrophages as measured by esterase staining.

clonal B-cell activators (PBAs). Anti-Ig antibodies are thought to function in this way and have been shown to be mitogenic for B cells[5–7]. Our laboratory has previously shown that soluble rabbit anti-mouse IgM or $F(ab')_2$ anti-IgM is mitogenic for mouse splenic B cells[8,9]. The response to intact anti-IgM only occurs with B cells from mice which are 7 months or older. In contrast, $F(ab')_2$ anti-IgM will stimulate B cells from both young and aged mice equally well suggesting that changes in B-cell Fc receptors may be involved in the age-dependent response to the intact anti-IgM molecule[10]. In all cases, the response rquires cross-linkage of surface μ heavy chains and is T-cell independent[10,11]. In the present study, we have investigated the macrophage requirement for anti-Ig stimulation. The requirement for macrophages in B-cell activation by PBAs, including anti-Ig reagents, is controversial[12,13]. We report that the proliferative response of B cells to intact anti-IgM is macrophage dependent whereas the response of the same cell population to $F(ab')_2$ anti-IgM is macrophage independent.

Spleen cells and peritonial cells were prepared from 8–10-month-old CBA/J mice. Peritoneal cells were obtained by lavage of the cavity with cold balanced salt solution containing 10% fetal calf serum (BSS-FCS). This procedure yielded $7–8\times10^6$ peritoneal cells per mouse of which at least 60% were macrophages as judged by esterase staining and which are hereafter referred to as peritoneal macrophages. When these cells were added to macrophage-depleted spleen cell cultures, the cell number was adjusted to compensate for non-macrophages. Spleen cells were prepared by gently pressing the tissue through a 60-mesh wire screen into cold BSS-FCS followed by two washes. Macrophages were depleted by a two-step procedure. First, the spleen cells were incubated for 90 min in BSS-FCS at 37 °C in plastic Petri dishes. Next, the non-adherent cells (2×10^8) were passed slowly through a Sephadex G-10 column[16] (18 cm^3 of packed Sephadex in a 20-cm^3 syringe) at 37 °C and eluted with warm BSS-FCS. Cells eluting in the first 5 ml were collected for culture. In several replicate experiments, this population contained 50–65% B cells and less than 1% macrophages as judged by immunofluorescent staining and esterase staining, respectively. Less than 0.1% of the G-10-passed cells were phagocytic for latex beads. Conditions for culture and stimulation with intact anti-IgM (anti-MC774 IgM myeloma)[8], $F(ab')_2$ anti-IgM[11] or lipopolysaccharide (LPS) are given in Table 1.

As shown in Table 1, unseparated spleen cells responded to all three stimulants. Macrophage-depleted spleen cells, however, failed to respond to intact anti-IgM but responded normally to $F(ab')_2$ anti-IgM and LPS. The lack of response to intact anti-IgM was not dose dependent; the cells remained unresponsive when cultured with a wide range of doses of anti-IgM (not shown). Addition of peritoneal macrophages (2%) to the macrophage-depleted spleen cell cultures completely restored, and actually enhanced, the response to intact anti-IgM. The response to $F(ab')_2$ anti-IgM was slightly increased whereas the response to LPS was somewhat inhibited. (Macrophages cultured alone at four different cell concentrations do not respond to any of the stimulants (data not shown).) Addition of increasing numbers of macrophages to the cultures (4% and 8%) reduced the response to intact anti-IgM to a level approximately equal to the response of unseparated spleen cells. At the same time, the response to $F(ab')_2$ anti-Ig remained relatively unchanged whereas the response to LPS was markedly inhibited. Responses to all three stimulants were significantly inhibited when 16% macrophages were added to the cultures. These results indicate that the macrophage requirements for stimulating B-cell proliferation with different anti-Ig reagents differ and depend, at least in part, on the molecular species of anti-Ig antibody used.

Mongini *et al.* have reported that the *in vitro* proliferative response of mouse B cells to soluble goat anti-IgM is macrophage dependent[15]. Our results confirm their findings, and we have extended the data to show that the response to $F(ab')_2$ anti-IgM is macrophage independent. In contrast, Sieckmann *et al.* have reported that intact anti-IgM stimulation of mouse B cells is macrophage independent[14]. However, as their culture media contained 2-mercaptoethanol (2-ME), that interpretation is not completely valid (see below).

It is not clear exactly why B cells require macrophages to respond to intact anti-IgM molecules but do not require accessory cells to respond to the $F(ab')_2$ form of the same molecule. Several possibilities must be considered. Additional experiments (not shown) have shown that 2-ME can substitute for macrophages and completely restore the response of macrophage-depleted spleen cells to intact anti-IgM. 2-ME is generally thought to replace supportive functions of macrophages related to cell viability[17]. It is unlikely, however, that the inability of macrophage-depleted cultures to respond to intact anti-IgM is due to problems of B-cell viability, as these same cultures respond normally to LPS and $F(ab')_2$ anti-IgM. Rather, 2-ME may simply potentiate the effect of the few remaining macrophages which are then able to support the induction of anti-IgM stimulation. This may involve the secondary or 'helper' signals provided by the macrophages. Alternatively, 2-ME may act independently and generate a cofactor from the serum which acts directly on the B cells[18]. Whatever the case, these secondary signals seem not to be required for stimulation by $F(ab')_2$ anti-IgM. A role for macrophage Fc receptors must also be considered. It is possible that macrophages bind the intact anti-IgM molecules through their Fc receptors and present them to the B cells in an insoluble matrix array. This would be similar to the stimulation of B cells by anti-Ig insolubilized on Sepharose beads as described by Parker[19]. However, this seems unlikely, as Mongini *et al.* reported that anti-IgM-pulsed and

washed macrophages could not stimulate macrophage-depleted B cells in the absence of additional soluble anti-IgM[15].

The interpretation we favour is that the differential requirement for macrophages is a reflection of different subsets of B cells responding to the two molecular forms of the anti-IgM antibodies. As these two stimulants differ only with respect to the presence of the Fc portion of the Ig molecules, differential sensitivity of the responding B cells to Fc receptor-mediated negative signals may also be involved. Recent experiments in our laboratory support these interpretations. We have found that complement receptor-positive (CR^+) B cells from aged mice (>7 months old) respond only to $F(ab')_2$ anti-IgM whereas CR^- B cells respond preferentially to intact anti-IgM[20]. The inability of CR^+ B cells to respond to the intact molecule is not reversed by addition of macrophages or 2-ME. Thus, it seems that intact anti-IgM and $F(ab')_2$ anti-IgM stimulate different populations of B cells and that these subsets have different signalling requirements for activation. In the context of this report, these findings suggest that depletion of macrophages from whole spleen cell populations selectively eliminates the ability of CR^- B cells to respond to intact anti-IgM.

Increased intracellular cyclic GMP does not correlate with protein discharge from pancreatic acinar cells

THE pancreatic acinar cell discharges secretory proteins in response to cholecystokinin–pancreozymin (CCK-PZ) and its analogues, or to cholinergic agonists such as carbamylcholine (carbachol). The mechanisms for stimulus–secretion coupling in the acinar cell are not known, although intracellular and, to some extent, extracellular Ca^{2+} are required[1–4], and a transient 10- to 20-fold increase in intracellular levels of guanosine cyclic 3′5′-monophosphate (cyclic GMP) accompanies onset of

Acini were prepared from pancreata of adult female guinea pigs using purified collagenase and mild mechanical shear[26,27]. Secretory proteins in acini to be used for measuring protein discharge were first pulse-labelled for 10 min at 37 °C with 4,5-^{3}H-L-leucine (5 μCi ml^{-1}, 40–60 Ci mmol^{-1}, Schwarz/Mann) in 10 ml of a solution (KRH) consisting of Krebs–Ringer's salts, 2% (v/v) essential and 1% non-essential amino acid concentrates (GIBCO), 2 mM L-glutamine, 14 mM D-glucose, 0.2% bovine plasma albumin (Reheis), 0.01% soybean trypsin inhibitor (Worthington) and 24 mM HEPES (Sigma), *p*H 7.4. Solutions were equilibrated with O_2. Following the pulse, unincorporated ^{3}H-leucine was removed by centrifugation and resuspension of acini in KRH. For determination of either secretory protein discharge or levels of cyclic GMP, acini from 1 g tissue were resuspended in 20 ml KRH containing an additional 3.8 mM unlabelled L-leucine, the substances indicated were added as 100-fold concentrates to 1-ml aliquots of the cell suspension, and incubation at 37 °C was continued for either 2 min (for cyclic GMP) or 2 h (for secretory protein discharge). MNNG was added to acini as a 100-fold concentrate in acetone. Addition of 1% acetone alone had no effect on either discharge or cyclic GMP response. Measurements of cyclic GMP were made on total acinar incubations (cells plus media). To monitor cyclic GMP recovery during purification, each incubation tube received 1.6 nCi ^{3}H-cyclic GMP (15 Ci mmol^{-1}, Schwarz/Mann) at the end of incubation and the reaction was stopped by addition of 0.5 ml 15% trichloroacetic acid (TCA) and freezing. The tubes were then thawed, sonicated for 30 s, centrifuged, and the supernatants passed over cation exchange resin[28]. To remove TCA, column fractions were extracted five times with eight volumes of water-saturated ether and lyophilised. Samples were redissolved in water and aliquots taken to determine cyclic GMP recovery (range: 40–90%). Cyclic GMP content was determined on the remainder of the sample by radioimmunoassay[29] with the modification that the antigen–antibody complex was precipitated with 7% TCA, *p*H 1.75. MNNG had no effect on antibody binding when added to the radioimmunoassay, and cyclic GMP from acini exposed to MNNG was sensitive to degradation by cyclic nucleotide phosphodiesterase (Boehringer, Mannheim). Total DNA in cell pellets was determined by the method of Burton[30]. Discharge of labelled secretory proteins was determined as described previously[31] following separation of acini and media by centrifugation at 800*g* for 5 min. Results are expressed as percentage discharge, defined as acid-precipitable d.p.m. in the media divided by total d.p.m. (cell pellets plus media) × 100. Values shown are means of triplicate determinations (±s.d.) from individual experiments. With 10^{-9} M caerulein, the average net percentage discharge (total minus resting) in 2 h was 26.4±2.3% (±s.e.m., n = 15), and the average cyclic GMP increase in 2 min was 20.8±4.8 times the basal level(±s.e.m., n = 9). Average responses to 10^{-4} M MNNG are listed in Table 2. NA, Not applicable.

induced discharge[5,6]. It has been proposed[5] that cyclic GMP may be a direct mediator of hormone-stimulated discharge, with the Ca^{2+}-dependent event either causing, or being caused by, increases in cyclic GMP[7,8]. To test this hypothesis, we have monitored the effects of several substances on secretory protein discharge and intracellular cyclic GMP levels in guinea pig

pancreatic acini. Our results, reported here, are not consistent with a role for cyclic GMP in a direct causative pathway leading to discharge, as four of the compounds tested (*N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG), sodium nitrite, hydroxylamine and sodium nitroprusside) elevated levels of cyclic GMP but did not trigger discharge, although acini treated with these agents remained competent to respond to natural secretagogues. Conversely, the phorbol ester 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA) did not affect cyclic GMP levels, but did elicit discharge. In contrast to observations on cyclic GMP, the requirement for extracellular Ca^{2+} correlated well with discharge. Our findings therefore do not support the hypothesis that cyclic GMP is directly involved in stimulus–secretion coupling, but are consistent with such a role for Ca^{2+}. A preliminary report of this work has appeared[9].

Compounds were chosen because they increased cyclic GMP in other cell types. TPA, a tumour-promoting alkaloid[10], increases cyclic GMP in skin fibroblasts, with concomitant stimulation of DNA synthesis[11]. TPA also activates platelets and increases platelet cyclic GMP[12]. MNNG and hydroxylamine activate guanylate cyclase[13,14] and elevate intracellular cyclic GMP[13,15] in liver and other tissues. Similar effects occur with sodium nitrite[13,16], sodium nitroprusside[17] and ascorbic and dehydroascorbic acids[18–20]. These compounds may activate guanylate cyclase by direct oxidation of a reactive group on the enzyme, perhaps by a mechanism involving nitroxide or another free radical as an intermediate[20].

MNNG did not trigger discharge in pancreatic acini, but dramatically increased cyclic GMP levels (Table 1). In a representative experiment (Table 1, experiment 1), 10^{-9} M caerulein, a decapeptide analogue of CCK-PZ[21], triggered the net discharge (total discharge minus unstimulated discharge) of 47% of secretory proteins in 2 h. Caerulein also caused a sixfold increase in cyclic GMP after 2 min. In contrast, MNNG did not stimulate discharge, although 10^{-3} M and 10^{-4} M MNNG caused 45- and 58-fold increases, respectively, in cyclic GMP levels. Acini treated with MNNG are, however, still competent to discharge secretory proteins in response to caerulein (Table 1, experiment 2). The fact that extremely high cyclic GMP levels did not affect the cellular response to caerulein suggests that cyclic GMP does not inhibit Ca^{2+} entry into pancreatic acini, a mechanism that has been postulated for smooth muscle[17]. In addition, stimulation of discharge by 10^{-5} M carbachol was also unaffected by 10^{-4} M MNNG (data not shown). The lack of discharge with MNNG is probably not due to its inactivation, as repeated addition failed to elicit discharge (Table 1, experiment 2). We have also determined that 10^{-4} M MNNG does not stimulate discharge of amylase from acini. Therefore, MNNG does not cause zymogen granule release, as amylase discharge primarily reflects this final secretory step.

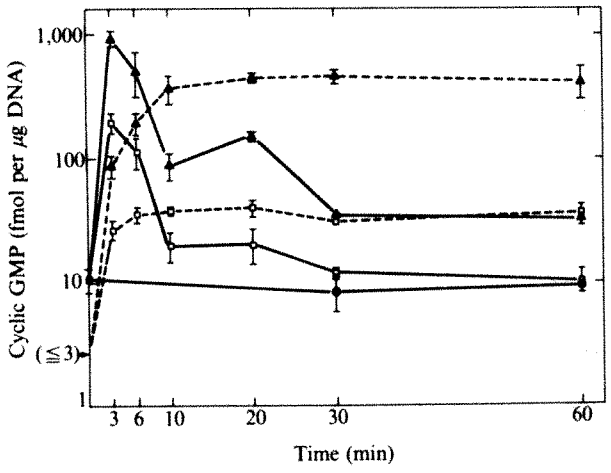

Fig. 1 Effect of MNNG 10^{-4} M and caerulein 10^{-9} M on intracellular and extracellular cyclic GMP levels in pancreatic acini as a function of incubation time. Acini were preincubated for 10 min at 37 °C in KRH (see Table 1) and then received either caerulein (□), MNNG (▲) or no additions (●). At the times indicated, the incubation mixtures were centrifuged and the media removed. Acini (——) and media (– – –) were analysed separately for cyclic GMP (see Table 1). Cyclic GMP levels in cells and media were normalised to DNA content of cell pellets. Note that cyclic GMP levels are plotted on a log scale. After 3 min, more than 95% of the total cyclic GMP is intracellular, justifying the procedure used in experiments shown in Tables 1 and 2 in which acini and media were not separated. Error bars represent ±1 s.d. for triplicate incubations from the same experiment.

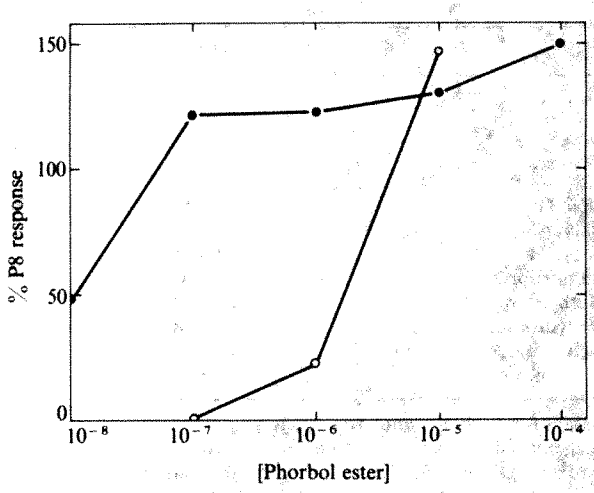

Fig. 2 Effect of TPA (●) and 4-*O*-methyl-TPA (○) on discharge from pancreatic acini. Discharge assays were carried out as described in Table 1. Phorbol esters were added from a 200-fold concentrated stock solution in dimethyl sulphoxide, which, when added alone at a concentration of 0.5%, had no effect on discharge. As experiments with TPA and 4-*O*-methyl-TPA were carried out on different days, the net discharge (total discharge minus resting discharge) was normalised to the net response elicited in the same experiment by the C-terminal octapeptide of CCK-PZ (P8), this being set at 100%. Data points are averages of duplicate incubations from single experiments. The normalised response to 10^{-7} M TPA in 2 h was 90 ± 17% (±s.e.m., $n = 3$). CCK-PZ octapeptide was from Dr Miguel Ondetti (Squibb) TPA and 4-*O*-methyl-TPA were from Consolidated Midland.

The cyclic GMP increase stimulated by MNNG is similar to that triggered by caerulein. Both are partially inhibited by the metabolic inhibitor carbonyl cyanide meta-chlorophenyl hydrazone (CCCP), and neither is affected by removing extracellular Ca^{2+}. The increase in cyclic GMP after 2 min in response to 10^{-9} M caerulein or to 10^{-4} M MNNG was inhibited by 83 ± 3% and 34 ± 4%, respectively, by 10^{-5} M CCCP (mean ±s.e.m., $n = 3$). CCCP also inhibits cyclic GMP increases stimulated by carbachol[5]. In contrast, removing extracellular Ca^{2+} (in the presence of 10^{-4} M EGTA) did not affect the increase in cyclic GMP caused by caerulein or MNNG. A Ca^{2+}-independent increase in cyclic GMP has also been observed in response to caerulein[7,8], carbachol[7,8] and the Ca^{2+} ionophore A23187 (ref. 8).

The time dependence for elevation of intracellular cyclic GMP by 10^{-9} M caerulein or 10^{-4} M MNNG is shown in Fig. 1 (solid lines). Within 3 min, caerulein stimulated an 18-fold increase in cyclic GMP, whereas the increase in response to MNNG was 87-fold. This larger increase with MNNG was consistently observed (see Table 1). Intracellular cyclic GMP levels decreased rapidly between 3 and 10 min after addition of the agents, and by 30 min the cyclic GMP concentration in caerulein-treated acini returned to unstimulated levels. The apparently higher level in MNNG-treated acini after 30 or 60 min may be due to cyclic GMP in the extracellular medium trapped within the cell pellets during centrifugation.

Cyclic GMP appears in the medium within 3 min after addition of caerulein or MNNG (Fig. 1, dotted lines) and plateaus

Table 2 Effect of various agents on cyclic GMP level and discharge response

Agent	Final concentration	Ratio of cyclic GMP (stimulated) to cyclic GMP (bkg) (2 min)	Normalised net discharge response (10^{-9} M caerulein = 100%) Agent alone (%)	Agent plus 10^{-9} M caerulein (%)
MNNG	10^{-4} M	79.9 ± 10.1 (12)	2.0 ± 1.6 (14)	112 ± 11 (4)
$NaNO_2$	10^{-3} M	22.4	−2.9	127
NH_2OH	10^{-3} M	162.0	−2.0	123
Na nitroprusside	10^{-3} M	93.3	4.5	113
Methylnitrosourea	10^{-3} M	1.9	0.2	97.6
Dehydroascorbic acid	10^{-2} M	0.8	0.03 ± 0.05 (3)	96.3
Dehydroascorbic acid	10^{-3} M	0.65 ± 0.05 (3)	−5.2 ± 12 (3)	81.3
Ascorbic acid	5×10^{-3} M	0.8	−0.9	92.8

Assays for discharge and cyclic GMP were as in Table 1. Incubation times were 2 min for cyclic GMP measurements and 2 h for discharge assays. The agents listed were added to acini as 100-fold concentrated stock solutions in acetone (MNNG (Aldrich), methylnitrosourea (K + K), dimethyl sulphoxide (DMSO) (for 10^{-3} M dehydroascorbate, K + K), or 0.15 M NaCl ($NaNO_2$, NH_2OH, sodium nitroprusside (all Fisher), ascorbate (Sigma)). A 1% concentration of acetone or DMSO had no effect on cyclic GMP levels or discharge rate. Dehydroascorbate 10^{-2} M was added as a twofold concentrated solution in KRH. Cyclic GMP levels in treated acini were divided by the level in untreated acini (bkg) in each experiment to yield the ratios listed in Table 2. The average cyclic GMP level in untreated acini was 23.0 ± 19.4 fmol per μg DNA (±s.e.m., $n = 19$). Discharge rates were corrected by subtracting the resting rate and normalised by setting the value for 10^{-9} M caerulein at 100%. Negative values indicate rates slightly below the resting rate. Where indicated, values are the mean ±s.e.m. for the number of experiments in parentheses. Otherwise, the data represent the mean of duplicate or triplicate incubations from one experiment.

after 10 min. Cyclic GMP is also released in response to carbachol[22]. Whatever the mechanism for release of cyclic GMP, in the case of MNNG it cannot be exocytosis of possible zymogen granule-associated cyclic GMP, as MNNG does not cause granule discharge.

The effects of six other compounds known to elevate cyclic GMP levels in other tissues[11–20] were also tested on pancreatic acini (Table 2). None of these substances elicited discharge, although sodium nitrite, hydroxylamine and sodium nitroprusside produced significant increases in cyclic GMP levels within 2 min. As is the case with MNNG, acini treated with each of the compounds remained responsive to caerulein.

In contrast to MNNG, TPA stimulated optimal discharge at doses from 10^{-7} M to 10^{-4} M (Fig. 2), but had no effect on cyclic GMP levels. TPA- and hormone-induced discharges were similar: both were inhibited by 10^{-5} M CCCP or by 10^{-4} M EGTA in Ca^{2+}-free medium. In addition, cell morphology after a 2-h incubation in 10^{-6} M TPA was consistent with normal stimulation when observed by electron microscopy. Amylase discharge in response to TPA paralleled discharge of labelled secretory proteins. The methylated TPA derivative, 4-*O*-methyl-TPA, was 100-fold less potent as a secretagogue (Fig. 2) and has greatly reduced tumour-promoting activity[10], suggesting that the mechanisms by which TPA acts as a tumour promoter and a secretagogue may be related. Finally, neither TPA nor 4-*O*-methyl-TPA significantly altered cyclic GMP levels, regardless of incubation time (10 s–1 h) or concentrations used (10^{-7}–10^{-4} M).

In conclusion, our experiments do not support the hypothesis[5] of a causal relationship between increased intracellular cyclic GMP and secretory protein discharge in pancreatic acinar cells. MNNG, hydroxylamine, sodium nitrite and sodium nitroprusside all increase cyclic GMP but do not elicit discharge (Table 1, Fig. 1, Table 2). Conversely, TPA triggers discharge (Fig. 2) but does not increase cyclic GMP. These findings are complemented by a recent report that cyclic nucleotide phosphodiesterase inhibitors elevate cyclic GMP but do not elicit discharge in rat pancreas[23]. We have also determined that neither MNNG, TPA nor caerulein affect cyclic AMP in guinea pig pancreatic acini. The possibility remains that cyclic GMP pools formed in response to MNNG and caerulein are located within different cellular compartments. This question could be resolved by immunocytochemistry[24].

Assuming that cyclic GMP is not a direct mediator of discharge, it seems that the most likely candidate is Ca^{2+}. Caerulein, carbachol and TPA failed to elicit discharge when Ca^{2+} was omitted from the medium and 10^{-4} M EGTA was included. Other secretagogues, including A23187 (ref. 25), require extracellular Ca^{2+}. Recently, Chandler and Williams[3] have suggested that secretagogues cause Ca^{2+} release from an intracellular membrane site which presumably must be replenished by Ca^{2+} influx across the plasma membrane. Whatever the mechanism for Ca^{2+} mobilisation, the question remains as to the nature of the proximal event following the increase in intracellular free Ca^{2+}.

The authors thank Ms Nora Glass for technical assistance and Drs Robert Study and Paul Greengard for gifts of antisera and iodine-labelled antigen for cyclic GMP radioimmunoassays. Supported by USPHS grant AM 17389 (J.D.J.) and by National Research Service Awards F32-GM 05284 and T32-GM 07562 (G.R.G.).

Rabbit skeletal myosin isoenzymes from fetal, fast-twitch and slow-twitch muscles

IT is generally accepted that myosin in vertebrate fast-twitch and slow-twitch muscles is structurally[1-4] and immunochemically[5-8] distinct and exists in several isoenzymatic forms[9-14]. The nature of myosin in developing mammalian skeletal muscles is controversial. Some authors[15,16] consider it to be identical to adult fast-twitch myosin on the basis of light-chain composition and histochemistry. Others[8] suggest that it may be a mixture of fast-twitch and slow-twitch myosins. Still others[4,17] maintain it is a distinct fetal form of myosin differing in primary structure from adult myosins. In this report we show that (1) myosin in both neonatal and adult fast-twitch muscles of the rabbit exists in three electrophoretically distinct isoenzymatic forms which differ in light-chain composition, and (2) the two-dimensional peptide map of the heavy chains of neonatal muscle myosin is distinct from maps of both fast-twitch and slow-twitch myosins. These results clearly establish the existence of fetal myosin isoenzymes in developing mammalian muscles and resolve apparent contradictions in the literature.

Pyrophosphate gel electrophoresis[9] has now been established as a sensitive and reliable method of resolving myosin isoenzymes differing in light-chain[13,18] or heavy-chain[19] composition. On analysis in this system, myosin from slow-twitch soleus muscle of the adult rabbit showed a single component (Fig. 1*a*). Adult fast-twitch longissimus dorsi muscle (Fig. 1*b*) showed three components (FM_1, FM_2 and FM_3) which migrated faster than the slow-twitch myosin. The longissimus dorsi muscle from a 2-day-old rabbit (Fig. 1*c*) also showed three components (fm_1, fm_2 and fm_3) which were electrophoretically faster than fast-twitch myosin components. However, a mixture of fast-twitch and fetal myosins (Fig. 1*d*) showed that fM_3 co-migrated with FM_1. Essentially the same profile of fetal components as shown in Fig. 1*c* was obtained from the developing slow-twitch soleus muscle of 2-day-old rabbits.

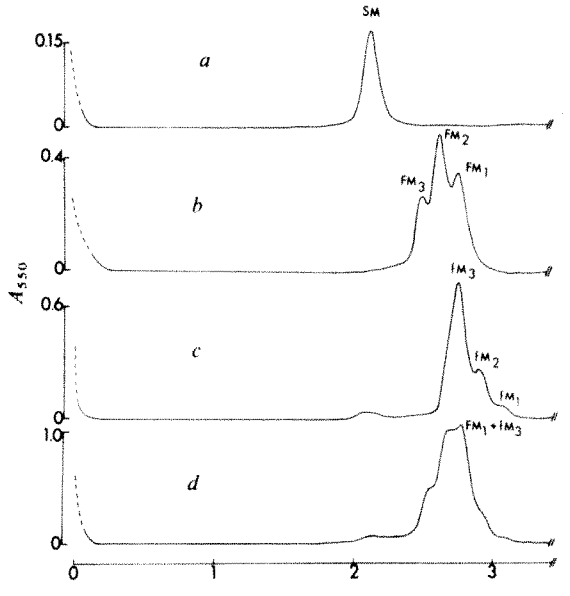

Fig. 1 Pyrophosphate gel electrophoresis of native myosins in polyacrylamide gels. Myosin was extracted and analysed in 4% polyacrylamide gels as described in refs 9 and 13. The curves show densitometer tracings of gels stained with Coomassie Brilliant Blue R. *a*, Slow-twitch myosin (SM) from adult rabbit soleus muscle; *b*, fast-twitch myosin components (FM_1, FM_2 and FM_3) from adult rabbit longissimus dorsi muscle; *c*, fetal myosin components (fM_1, fM_2 and fM_3) from the longissimus dorsi muscle of a 2-day-old rabbit; *d*, mixture of *b* and *c*, showing that FM_1 co-migrates with fM_3.

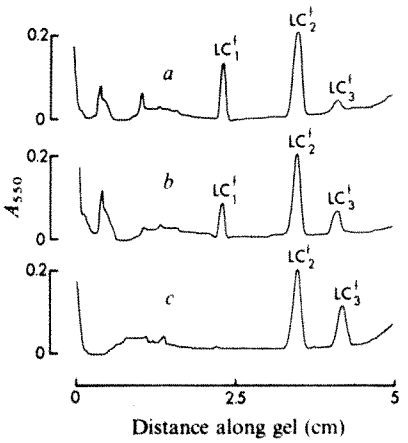

Fig. 2 SDS gel electrophoresis of myosin light chains from electrophoretically purified adult fast-twitch myosin components. After pyrophosphate gel electrophoresis, portions of the gel containing individual components were cut out and analysed for myosin light chains by SDS gel electrophoresis in 12.5% polyacrylamide gel as described in ref. 13. The curves are densitometer tracings showing the distribution of the three fast-twitch myosin light chains from three consecutive slices of the same pyrophosphate gel: *a*, LC_1^f (or A1), LC_2^f (DTNB light chain) and LC_3^f (A2), in FM_3; *b*, FM_2; *c*, FM_1. LC_1^f is absent from FM_1, the ratio $LC_2^f:LC_3^f$ for this component is approximately 1:1. In FM_2, all three light chains are present, the ratio $LC_1^f:LC_2^f:LC_3^f$ was approximately 1:2:1. A small amount of LC_3^f is present in the FM_3 slice from this particular pyrophosphate gel. Its presence is due to a slight contamination with FM_2 in this slice, as it is absent from the FM_3 slice of other gels. Because gels were sliced using a stained companion gel as a guide, it was difficult to avoid some contamination in one of the three consecutive slices. Where FM_3 was not contaminated by FM_2, the ratio $LC_1^f:LC_2^f$ was approximately 1:1. Apart from problems arising from contamination by neighbouring components, the distribution and stoichiometry of the light chains described here have been confirmed in several electrophoretic runs.

The isoenzymatic nature of the six components from adult fast-twitch and fetal myosins is shown by the analysis of their light-chain composition by methods described previously[13]. Figure 2 shows the result of light-chain analysis for FM_3 (Fig. 2*a*), FM_2 (Fig. 2*b*) and FM_1 (Fig. 2*c*). These results suggest that the light-chain composition in rabbit fast-twitch myosin isoenzymes is identical to the homologous chick fast-twitch myosin isoenzymes[13], being $(LC_2^f)_2(LC_3^f)_2$, $LC_1^f(LC_2^f)_2LC_3^f$ and $(LC_1^f)_2(LC_2^f)_2$, respectively.

Myosin from developing mammalian muscles contains three light chains which are indistinguishable from LC_1^f, LC_2^f and LC_3^f on SDS gel electrophoresis[15,20-23]. Analysis of light chains from individual fetal myosin components (Fig. 3) showed that fM_1, fM_2 and fM_3 are homologous to FM_1, FM_2 and FM_3, respectively, in light-chain composition. Although FM_1 co-migrated with fM_3, their different light-chain compositions show them to be different isoenzymes. As light chains constitute only a small fraction of the total molecular mass of native myosin, the difference between fetal and fast-twitch myosins with respect to their electrophoretic behaviour suggests that the heavy chains of these two types of myosin may be structurally different. This is borne out by peptide mapping of myosin heavy chains.

Cyanogen bromide digestion is a convenient method of treating myosin heavy chains for peptide mapping, as the number of peptide fragments is kept to a manageable level compared with the use of trypsin. Two-dimensional mapping of cyanogen bromide peptides has been used successfully to examine structural differences in the heavy chains of ventricular myosin isoenzymes in the rat[19] and is here applied to the analysis of the heavy chains of the three types of skeletal myosin. The maps

© Macmillan Journals Ltd 1979

(Fig. 4) for fast-twitch (adult longissimus dorsi, 3-day-old rabbit) and slow-twitch (adult soleus) myosins are clearly different. These maps are consistently reproducible from experiment to experiment. The greater complexity of the map for fast-twitch myosin heavy chains when compared with maps of the other two myosins may be related to the known heterogeneity of the fast-twitch myosin heavy chains[24,25]. Fetal peptides mapped in the more acidic regions of the gel compared with those of the other two myosins. This is consistent with the higher electrophoretic mobility of the fetal myosin isoenzymes in pyrophosphate gels. The maps suggest that the heavy chains of the three types of myosin are structurally distinct. This view is corroborated by earlier findings that (1) the patterns of release of tryptic peptides from these three types of myosins are different[4], and (2) a fetal myosin peptide, differing in amino acid sequence from its homologue obtained from adult muscle, can be isolated from neonatal rabbit muscle[17].

This work provides direct evidence for the existence of a new class of myosin isoenzymes in developing mammalian skeletal muscles which is distinct from those in adult fast-twitch and slow-twitch muscles. An unexpected structural feature of these fetal myosin isoenzymes is that their light-chain types and distribution are so similar to those of the fast-twitch myosin isoenzymes while heavy chains of these two types of myosins are structurally different. This fact has led to the erroneous conclusion that the myosin in developing mammalian muscle is identical to that of adult fast-twitch myosin[15,16]. It also explains the immunohistochemical reaction between anti-fast-twitch light-chain antibodies and developing fast-twitch and slow-twitch muscle fibres[8]. The reaction between antisera raised against slow-twitch myosin and developing muscle fibres[8] may be attributable to common antigenic determinants in fetal and slow-twitch myosins.

This work has helped to define the pattern of changes in myosin gene expression during muscle differentiation in the mammal. Contrary to earlier views[8,15,16], it shows that both fast-twitch and slow-twitch muscles synthesise the same fetal myosin isoenzymes early in development. Subsequently, fetal myosin isoenzymes are replaced by the appropriate adult fast-twitch or slow-twitch myosin isoenzymes. During the development of the fast-twitch muscle, this change may principally involve the genes for the heavy chains. Recent work[26] has

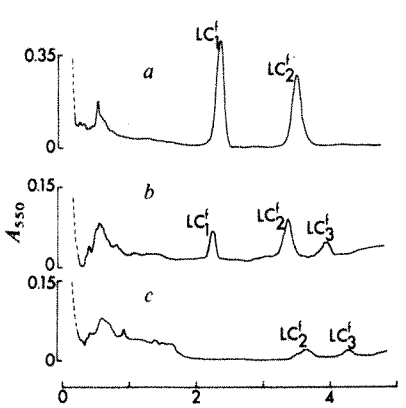

Fig. 3 SDS gel electrophoresis of myosin light chains from electrophoretically purified fetal myosin components. The methods used were the same as those described for Fig. 2. *a*, Light chains from fM_3 showing LC_1^f and LC_2^f only, occurring in approximately equal proportions; *b*, light chains in fM_2, in which $LC_1^f : LC_2^f : LC_3^f$ is approximately 1 : 2 : 1; *c*, light chains in fM_1, showing LC_2^f and LC_3^f only and occurring in approximately equal proportions. These results were obtained from consecutive slices of the same pyrophosphate gel. The results for fM_2 and fM_3 have been consistently obtained in many different runs, but fM_1 presents more difficulty as it constitutes only a small fraction of the fetal myosin. However, a similar result has been obtained in another experiment.

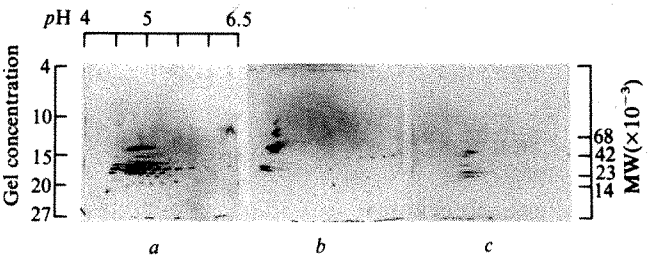

Fig. 4 Two-dimensional cyanogen bromide peptide maps of myosin heavy chains. These maps were obtained for adult fast-twitch myosin (*a*), fetal myosin (*b*) and adult slow-twitch myosin (*c*) using methods described in detail in ref. 19, and briefly outlined below. Myosin heavy chains were separated from carboxymethylated crude myosin extracts through a Sepharose 4B column in a denaturing solvent. The heavy-chain fraction was dialysed and then digested with cyanogen bromide in 70% formic acid at 4 °C for 60 h. The peptides were analysed by isoelectrofocusing in the first dimension between *p*H 4 and 6.5 and by SDS gel electrophoresis in gradient gels (Gradipore) in the second dimension. Gels were stained in Coomassie Brilliant Blue R. The three slabs were analysed simultaneously in the same electrophoresis unit. Gel concentration along the slab is indicated on the left. The scale on the right marks the positions of molecular weight markers, the numbers giving molecular weights in thousands.

demonstrated that the bulk of the light chains from developing mammalian muscle is indistinguishable in charge as well as in size from those of adult fast-twitch myosin, suggesting that they may be products of the same set of genes. However, in addition, a minor component, called embryonic LC_1, distinct in charge but similar in size to LC_1^f, has also been identified[26].

The existence of fetal isoenzymes of myosin in the mammal during the perinatal period is in apparent contrast to the situation in the chick[27]. Avian fast-twitch and slow-twitch muscles in the 11–14-day chick embryos apparently already synthesise some of the myosin isoenzymes found in the adult muscles. A distinct fetal myosin is apparently absent in both these types of avian muscle at about this time. A possible reason for this difference between rabbit and chick may be that chick fetal myosin is synthesised much earlier than the 14-day embryo. Alternatively, chicken fetal myosin homologous to those demonstrated here may be present in the 11–14-day embryos, but has not been resolved in pyrophosphate gels from adult myosin isoenzymes present during this period of development.

Fast and slow muscles in tissue culture synthesise only fast myosin

ADULT fast and slow skeletal muscle fibres contain different myosins, a result of innervation by different classes of motoneurones[1]; innervation of one fibre type by the opposite motoneurone type leads to a switch in the kind of myosin synthesised[2,3] within pre-existing fibres[4,5]. In embryonic muscles, however, the particular myosin isozyme synthesised before and during the early stages of innervation has been a subject of controversy. Some investigators claim that all embryonic muscle fibres—whether destined to be fast or slow in the adult—initially synthesise both fast and slow myosins[6,7]. Proper innervation would then lead to a selection of one myosin type and repression of the other type within each cell. Others propose that the myosin of embryonic muscles is a distinct myosin, unique to the embryo[8,9]. On the other hand, we have presented evidence that all fetal muscles have an intrinsic programme which causes them to synthesise fast myosin initially[10,11]. After innervation, fast muscles continue synthesising fast myosin, while slow muscles switch to the synthesis of slow myosin. Some studies have corroborated our findings[12–14], but in all these studies the earliest fast and slow muscles that could be obtained were already innervated, and the slow muscles already contained a small amount of slow myosin. Accordingly, to examine the initial myosin synthesised in both fast and slow muscles before innervation, we have cultured tissue from chicken muscles destined to be fast or slow muscles in the adult. Muscle fibres in tissue culture are formed in the complete absence of innervation. Whether established from presumptive fast or presumptive slow muscles, all fibres in culture synthesised only fast myosin heavy and light chains.

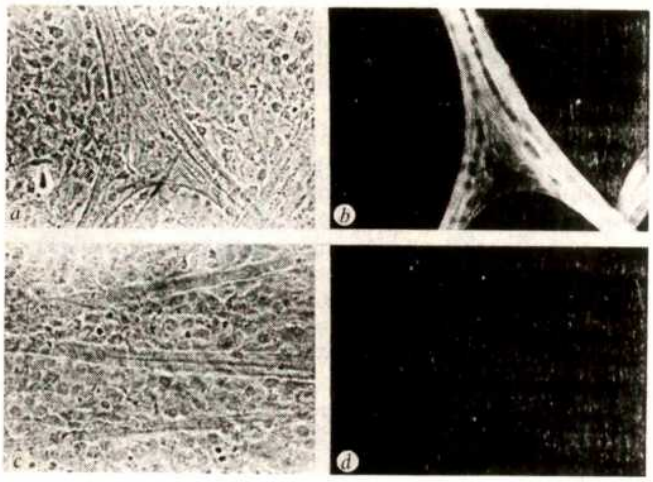

Fig. 1 Staining of cultured pectoralis muscle with fluorescent antimyosins. Muscle was cultured from an 11-d embryonic pectoralis muscle. After 7 d, cultures were fixed in acetone/formaldehyde, stained with affinity-purified, fluorescein-labelled AFHC or ASHC, destained, and photographed on a Zeiss Photomicroscope II equipped with epifluorescence. The production of anti-fast and anti-slow myosin heavy chain IgG has been described previously[15]. Affinity-purified AFHC and ASHC were prepared from the IgG by two rounds of absorption. First, each IgG was absorbed to its homologous myosin bound to PAB-cellulose (for example anti-fast IgG absorbed to fast myosin)[15]. The absorbed material was recovered and re-absorbed against the heterologous myosin type (for example anti-fast myosin antibody absorbed against slow myosin) to remove any cross-reacting antibodies. The final antibodies are specific to either fast or slow myosin heavy chains and show Ouchterlony reactions identical to those shown previously[10,15]. *a*, *c*, Phase micrographs of cultured pectoralis fibres surrounded by mononucleated non-muscle cells. *b*, Same field as (*a*), stained with fluorescent AFHC. *d*, Same field as (*c*), stained with fluorescent ASHC × 100.

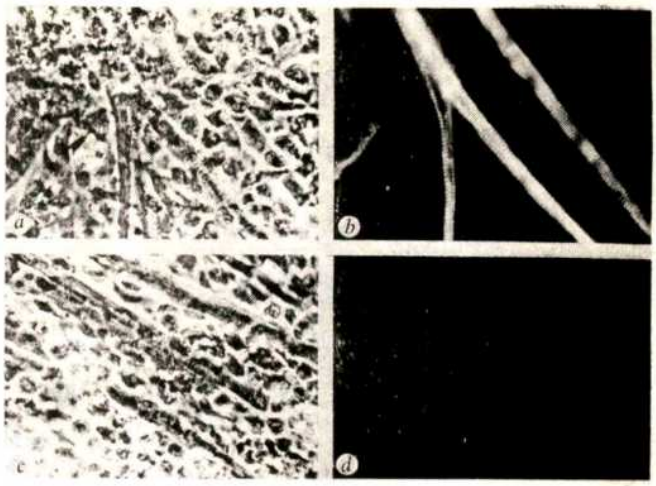

Fig. 2 Staining of cultured ALD muscle with fluorescent antimyosins. Muscle was cultured from a 12-d embryonic ALD muscle. After 7 d, cultures were fixed and stained as described in Fig. 1. *a*, *c*, Phase micrographs of cultured ALD fibres surrounded by non-muscle cells. (*b*), Same field as (*a*), stained with AFHC. (*d*), Same field as (*c*), stained with ASHC × 100.

Cultures of embryonic pectoralis (presumptive fast) and embryonic anterior latissimus dorsi (ALD) (presumptive slow) muscles were stained with affinity purified antibodies specific to adult chicken fast and slow myosin heavy chains. All fibres react only with the anti-fast myosin heavy chain antibody (AFHC) (Figs 1*b*, 2*b*). No reaction can be detected with the anti-slow myosin heavy chain antibody (ASHC) in either the pectoralis (Fig. 1*d*) or ALD (Fig. 2*d*) fibres. Replicating fibroblasts surrounding the fibres contain neither muscle-specific myosin.

These results do not agree with those of several other investigators. Masaki and Yoshizaki[6] claimed that cultured chicken pectoralis fibres reacted with antibodies against both fast and slow chicken myosins. Their failure to completely purify the myosin used as antigen and failure to affinity purify the antibodies[6,16] probably led to gross contamination of the anti-myosin antibodies with antibodies to non-myosin proteins, as others have demonstrated[17]. Similarly, Gauthier *et al.*[7] reported that when cross-sections of embryonic rat muscles were stained with antibodies to adult chicken fast and slow myosins, all fibres reacted with both antibodies. We have found, however, that affinity purified anti-chicken myosin antibodies, while staining rat muscle cross-sections, fail to stain the A bands of purified rat myofibrils or show a reaction against rat myosin on immunodiffusion gels (N.A.R. and A. Kelly, unpublished observations). Conversely, Bruggmann and Jenny[18] have shown that anti-rabbit myosin antibodies do not react with chicken myosin.

The ALD and pectoralis cultures might contain small amounts of slow myosin heavy chains not detectable by immunofluorescence. Therefore, cultures were labelled for 24 h with ^{35}S-methionine, washed, and each culture mixed with ~10-fold excess of both unlabelled fast and slow muscle from an

0028–0836/79/300323—03$01.00

© Macmillan Journals Ltd 1979

adult chicken. The labelled myosins from the cultures and the unlabelled adult myosins of these mixtures were co-purified and diffused against AFHC and ASHC. As the pectoralis and ALD cultures had been mixed with adult unlabelled fast and slow muscles, each preparation contains unlabelled fast and slow myosin and each shows a reaction against both AFHC and ASHC when the immunodiffusion gels are stained (Fig. 3*a*, *b*). An autoradiograph of these gels, however, reveals that only the precipitin line against AFHC (Fig. 3*c*) contains radioactive myosin—myosin that must have been synthesised in the labelled ALD and pectoralis cultures. Thus, both ALD and pectoralis fibres in culture contain heavy chains reacting identically with AFHC on immunodiffusion plates. The fact that neither culture contains radioactive heavy chains reacting with ASHC (Fig. 3*d*) cannot be attributed to a failure to reach an equivalence point of antigen and antibody, since the stained gel clearly shows that an equivalence point of ASHC with slow myosin heavy chains was present. The absence of a radioactive precipitin line with ASHC must mean that no slow myosin heavy chains are synthesised in either culture.

Does the radioactive precipitin line in Fig. 3*c* really represent fast heavy chains or does it merely indicate some cross reaction with an 'embryonic' heavy chain? The radioactive myosin of the precipitin line represents cultured myosin which is less than 10% of the total myosin. This radioactive line exactly overlays the precipitin line seen after staining; the stained line, however, represents over 90% unlabelled adult fast heavy chain and less than 10% radioactive heavy chain from the cultures. That the equivalence point of AFHC with adult fast heavy chains and the equivalence point of labelled cultured myosin with 'cross-reacting' antibodies would coincide so exactly is unlikely. When these myosin samples were diluted 1:1 with only unlabelled adult myosin, the radioactive precipitin line still coincided exactly with the stained precipitin line (data not shown). Thus, although we halved the concentration of labelled myosin, its equivalence point was still the equivalence point of adult fast heavy chain with its antibody. Hence, it is unlikely that the radioactive heavy chains from the ALD and pectoralis cultures differ antigenically from adult fast myosin heavy chains.

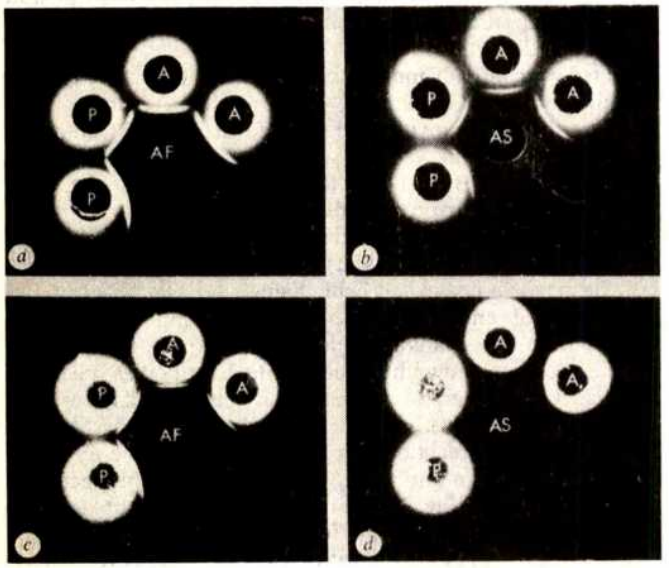

Fig. 3 Myosins from cultured ALD and pectoralis muscles diffused against specific anti-myosins. Myosins were isolated from mixtures of ^{35}S-methionine labelled cultures with unlabelled adult fast and slow chicken muscles. The co-purified myosins were diffused against AFHC and ASHC as previously described[10]. After diffusion, the gels were washed, stained with 1% thiazine red, and destained. The gels were then dried and autoradiographed with Royal X-Omat film for 48–72 h at −80°. In (*a*), AFHC was placed in the centre well. The left two wells (P) contained ^{35}S-methionine labelled myosin from pectoralis cultures mixed with unlabelled adult fast and slow myosins. The right two wells (A) contained ^{35}S-methionine labelled myosin from ALD cultures mixed with unlabelled adult fast and slow myosins. The total myosin concentration in each well was approximately 3 mg ml^{-1}. Since each preparation contained unlabelled adult fast myosin heavy chains, the AFHC reacted with each with a single precipitin line. *c*, Autoradiograph of (*a*). Both ALD and pectoralis cultures contained labelled myosin which reacted with AFHC. The precipitin line in (*c*) exactly coincides with the line in (*a*). In (*b*), ASHC was placed in the centre well, while the peripheral wells were filled as in (*a*). Since each preparation contained unlabelled adult slow myosin heavy chains, the ASHC reacted with each with a single precipitin line. *d*, Autoradiograph of (*b*). Neither the ALD nor the pectoralis cultures contained labelled myosin which reacted with ASHC.

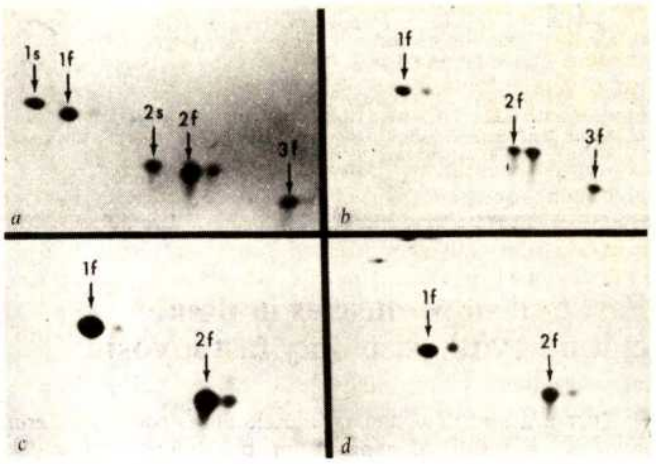

Fig. 4 Two-dimensional electrophoresis of myosin light chains. Myosins isolated by conventional methods[10] were subjected to electrophoresis on isoelectric focusing gels over *pH* range 4–6, followed by SDS-polyacrylamide gel electrophoresis on 15% acrylamide gels. In each figure, the more acidic region is on the right. *a*, *b*, Gels stained with Coomassie brilliant blue. *c*, *d*, Fluorographs of labelled cultured myosins which had been mixed with unlabelled adult fast and slow myosins as carriers and markers. Light chains were identified by comparison of fluorographs with the stained gels. Light chains were derived from adult chicken ALD (slow) and pectoralis (fast) myosins (*a*); adult pectoralis myosin alone (*b*); ^{35}S-methionine labelled pectoralis culture myosin (*c*); and ^{35}S-methionine labelled ALD culture myosin (*d*). Slow myosin light chains are 1s and 2s; fast myosin light chains are 1f, 2f, and 3f. The light chain to the right of 2f is the phosphorylated form of 2f. The chain to the right of 1f may be a secondary modification of 1f; others have claimed that it is a unique embryonic form of the myosin light chain[8]. It is present in both adult and cultured chicken myosins.

To examine the myosin light chains more closely, myosins from ^{35}S-methionine labelled ALD and pectoralis cultures (mixed with unlabelled adult fast and slow myosins as carriers and markers) were subjected to electrophoresis on two dimensional gels[19]. Figure 4*a* shows the light chains of a mixture of adult fast and slow light chains. When compared to previous one-dimensional gel analyses[10], which separate proteins only on the basis of molecular weight, some of these light chains show an increase in heterogeneity. Light chain 2f (LC_{2f}) appears as a doublet; the more acidic protein is the phosphorylated form of this light chain. Often, LC_{2s} is also present in its phosphorylated and non-phosphorylated forms, although only the non-phosphorylated chain is evident in Fig. 4.

LC_{1f} also appears as a doublet, with a dominant band accompanied by a minor band at its acidic side. This minor band, which varies in intensity in different preparations, can be seen in all our adult fast and cultured embryonic myosins (see below). Although barely detectable in this mixture of adult fast and slow

myosins (Fig. 4*a*), it is seen clearly in a different preparation of adult fast myosin alone (Fig. 4*b*).

When fluorographs are prepared from the cultured ALD (Fig. 4*d*) and cultured pectoralis (Fig. 4*c*) muscle myosins after two-dimensional electrophoresis, the dominant light chains co-migrate with adult LC_{1f} and LC_{2f}. In both figures, LC_{2f} is present in both the phosphorylated and non-phosphorylated forms. LC_{1f} is also present as a doublet. Whalen *et al.*[8] have seen a minor peptide similar to this satellite of LC_{1f} in myosins isolated from fetal, neonatal, and cultured rat fast muscles, although not in myosin from adult rat muscles; for this reason, they consider it an embryonic light chain. However, when RNA from cultured rat myotubes is translated in an *in vitro* system, this minor band is not seen (ref. 20, Fig. 6). In addition, this peptide has been detected in both adult and embryonic muscles of the chicken, cat, and rabbit (A. Kelly and N.A.R. in preparation). Hence, there is no compelling evidence to suggest that this is a distinct embryonic gene product, as proposed by Whalen *et al.*[8]

It has been shown previously that LC_{3f} is not present in cultured chicken muscle or in embryonic chicken muscles *in vivo*[10,21,22]. The bands migrating near the position of adult LC_{3f} and several others result from fibroblast contamination of the cultures. Neither ALD nor pectoralis cultures show any bands migrating with either LC_{1s} or LC_{2s}.

Muscle fibres in tissue culture, then, whether arising from potential fast or slow muscles *in vivo*, synthesise myosin heavy and light chains identical by several criteria to those in adult fast muscles. Combined with previous *in vivo* studies[10–14], this suggests that all pre-innervated skeletal muscle fibres, regardless of their destiny, synthesise only fast myosin. Thus, the initial expression of the fast myosin gene may be considered an endogenously programmed event in the development of both fast and slow muscles. Some motoneuronal contribution to myogenesis apparently can override this endogenous commitment and cue individual fibres to cease synthesising fast myosin and begin synthesising slow myosin, a process which occurs in normal slow muscle development. This contribution is most likely the specific pattern of impulses generated by the motoneurone[23–25].

Filament geometry and the activation of insect flight muscles

HIGH wingbeat frequencies are required for flight in many insects, and have led to striking specialisations[1]. The thorax and wings form a resonant system whose oscillation is sustained by alternating contractions of antagonistic muscles. The action of these flight muscles is to produce only a small-amplitude deformation of the thorax, mechanically amplified into wing movements. The muscles are diverse in arrangement[1] and ultrastructure[2]. In several insect orders, they are of a characteristic 'fibrillar' type whose very regular architecture is well known[3]. As recognised largely through the work of Pringle[4], certain properties of fibrillar muscle permit more rapid wingbeats because the oscillation does not depend on pacemaking neural input: the muscles receive only slow and irregular stimulation, and the contraction of each is triggered, after a delay, directly by the stretch applied to it while its antagonist shortens. Studies of isolated glycerol-extracted fibrillar muscle fibres show that unusual properties underlying this sensitivity to stretch are intrinsic to the contractile apparatus itself[5]. ATPase levels and tension are low in calcium-activated fibres at rest length, but are increased by slight extension (0.1–5%). The muscles exhibit both actin-linked and myosin-linked regulation typical of many invertebrate muscles[6], and the additional regulatory effects of mechanical conditions are not understood. Stretch has been presumed to modify cross-bridge attachment by some unknown effect on the myosin filaments[4] (possibly transmitted through structures which connect them to the Z-line in certain insect muscles[7]). I suggest here that many aspects of stretch-activation in fibrillar muscles may be explained by the particular geometry of their myosin and actin filaments.

The staggered array of six actin filaments round each myosin filament in the lattice[3] is shown in Fig. 1*a*, 'unrolled' to form a radial projection. The solid bars are regions analogous to 'target areas' of the rigor state[3], assumed to be accessible to attachment of active bridges, and they occur every 385 Å along each filament. Two different sets of helical tracks with an axial separation of 385 Å are marked. Figure 1*b* shows the locations of myosin cross-bridges on the thick filament. These lie on helical tracks whose axial separation is again 385 Å, as indicated by the X-ray pattern of the relaxed muscle[8]; the number of such tracks is not yet firmly established, and Fig. 1*b* follows the suggestion[9] that there may be four rather than two[8] or six[10]. Superimposing *a* and *b*, the relationship between cross-bridges and their surrounding envelope of actin targets is seen to depend on the filament alignment. Thus, in *c*, all targets are beyond the 'reach' of the nearby bridges, whereas in *d* all are accessible. Different alignments of actin and myosin filaments are therefore not equivalent: the relationship between tracks of bridges and of targets does not vary throughout each half-sarcomere, but does alter when the alignment is changed by extending the muscle. (When actin and myosin periods are not related, changes occurring locally as a result of extension are largely 'averaged out' over the length of the sarcomere.)

The clear difference between *c* and *d* in Fig. 1 results because *a* and *b* have one set of helical tracks in common, with respect to number, pitch and hand (namely, the four-start tracks of pitch 385 Å), and because targets and bridges are both envisaged as having limited spatial extents. Similar effects result with certain other myosin structures: for example, the two-start myosin helix[8], if its hand is opposite to that of *b*. (The hand of the actin lattice is known, whereas that of the myosin helix is not[3].) In either of these cases, the alternation of match and mismatch repeats after 385 Å of relative movement of the filaments. The six-start myosin helix of Squire[10] permits a much less dramatic difference between match and mismatch, repeating after a movement of only 128 Å.

Filament sliding can therefore greatly influence opportunities for bridge attachment. To illustrate in a general way how these

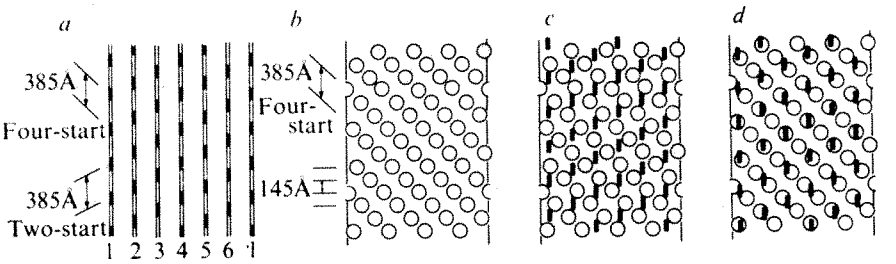

Fig. 1 Radial projections of actin envelope (*a*) and myosin surface lattice (*b*) in insect fibrillar muscle. Bars in *a* represent regions of thin filaments accessible to bridge attachment. Circles in *b* represent units of the cross-bridge array, presumably two myosin heads in an as yet unknown relationship. Matching of one set of helical tracks in the two lattices means that average proximity of bridges to attachment regions varies with alignment of the filaments (*c* and *d*). How far they can be completely segregated, as in *c*, depends on their respective dimensions. The size of circles in *b* reflects a substantial disorder in the cross-bridge array. The matching must have effects on the dynamics of the activated muscle which have no counterpart in cases where a 'vernier' relation exists between thick and thin filament periods. State *c* is considered the 'ground state' for the muscle at its rest length, whether activated or not. (This state is assumed to be maintained for some structural reason, such as a sterically preferred alignment of the myosin helices with the thin filament components. The preferred alignment will be attainable even in isometric conditions, if a slight dispersion of sarcomere lengths throughout the fibre can occur.) Other states than *c* will result following stretch, and in activated muscle will generate different levels of activity (see text); during small-amplitude oscillation, the alignment will vary cyclically over some part of the range *c*–*d*.

effects can modify conventional muscle dynamics, I assume the four-start matching shown in Fig. 1. The complete mismatch *c* might explain how rest-length fibrillar muscle fibres can be fully calcium-activated and yet develop little tension (see also Fig. 1, legend). Slight extension of the fibres will increase the accessibility of bridges to targets. The observed response to stretch, in both insect and vertebrate muscles, includes certain rapid transient effects[11] followed by delayed tension changes. The latter are generally understood to reflect the equilibration of cross-bridges between different attached and detached states in their new environments, at a rate governed by that of cross-bridge turnover[12]. Insect fibrillar muscles are distinctive in that the delayed tension change is large and does not ultimately reverse but instead approaches a different level at the new muscle length. In these terms Fig. 1 suggests a structural reason, hitherto only conjectural, that steady tension might be affected by a length change in fibrillar muscle. It is natural to expect the magnitude of the new tension to depend, perhaps not linearly, on the proximity of bridges to targets. This proximity in turn depends on the amount of extension; it alternately increases and declines with a repeat of 385 Å (about 3% of half-sarcomere length in *Lethocerus*) if Fig. 1 is interpreted literally. But other structural effects might accompany stretch, such as tension-induced changes in myosin helix pitch, non-uniform elongation of sarcomeres, and altered register across the filament lattice. Extension by 3% will then not restore the initial filament alignment immediately, and tension after a stretch will not vary in a periodic manner with the amount of extension. Nevertheless, a periodicity of about 3%, superimposed on other effects, is indeed observed when stretches are applied in sufficiently small and rapid steps[13], in contrast to earlier observations[14,15].

The rapid activation and inactivation of fibrillar muscles could thus be coupled to their small oscillatory length changes through their specialised filament structure. Certain geometrical relationships, accurately preserved throughout the highly regular filament lattice, would ensure that opportunities for bridge attachment can be modulated simultaneously throughout a bundle of muscle fibres in synchrony with the wingbeat cycle. The requisite matching of actin and myosin periods can be related to the unmatched structure in certain non-fibrillar crustacean and insect muscles, through small changes in the 'twist' of the myosin filament[9]. If further work confirms that such geometric effects indeed occur, the present description must be refined in the light of the complex non-linear dynamics of fibrillar muscles. The alternative geometries underlying the sensitivity of activation to stretch should perhaps be manifest also in the rigor state, or when ATP is replaced by its analogues. Finally, it will be interesting to consider how so specialised an adaptation to oscillatory activity can meet the widely varying requirements of flight in different insect species.

Transition temperature of excitation–contraction coupling in frog twitch muscle fibres

THE mechanism by which depolarisation of the muscle fibre membrane leads to release of stored Ca^{2+} ions from the sarcoplasmic reticulum, although crucial, is perhaps the least understood stage in excitation–contraction coupling[1,2]. We report here our investigation of the temperature dependence of this mechanism, using intracellular injection of arsenazo III (refs 3, 4), a Ca^{2+} indicator dye with a fast response time[5]. We have found that the latency between depolarisation of the fibre and the onset of the rise in intracellular free Ca^{2+} is proportional to the reciprocal temperature, but that on an Arrhenius plot this relationship shows a change in slope at a temperature which depends upon the Ca^{2+} concentration in the bathing solution.

Experiments were carried out on the cutaneous pectoris muscle of *Rana temporaria*, stretched to a striation spacing of about 3.6 μm to reduce contraction. The bathing solution contained (in mM): NaCl, 120; KCl, 2; 0, 1.8 or 12 $CaCl_2$. In the 0 Ca^{2+} solution, 1 mM EGTA and 5 mM $MgCl_2$ were added; *p*H was adjusted to 7.2. The temperature of the solution was controlled by Peltier elements in the base of the chamber, and was measured by a thermistor close to the muscle. Fibres were penetrated with two micropipettes, for voltage recording and dye injection. The dye pipette also served as a current-passing electrode for initiating action potentials, or for voltage clamping. Intracellular Ca^{2+} changes were recorded as previously described[3,6,7]. Briefly, arsenazo III was injected into a fibre by ionophoresis, and light transmission through the fibre was measured at wavelengths of 532 and 602 nm from a spot of 80 μm diameter. Electrical subtraction of these two signals gave a

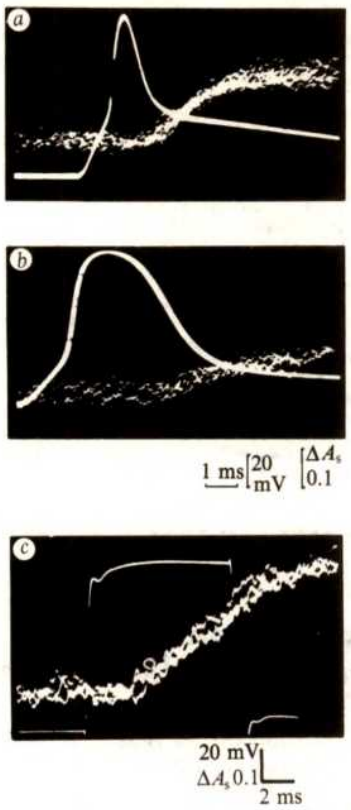

Fig. 1 Delay of the arsenazo III light response following stimulation by action potentials (*a*, *b*), and a voltage-clamped depolarising pulse (*c*). In each record the upper (noisy) trace shows light transmission changes from the arsenazo III-loaded fibre, at the wavelength pair 532–602 nm, and the calibration bars give the standardised change in light absorption, ΔA_s (see ref. 6). The lower traces show the membrane potential. Each record is a superposition of three to four sweeps. The records were obtained from different fibres, at the temperatures indicated. Ringer's solution contained 1.8 mM Ca^{2+} in all cases, and in *c* 2×10^{-6} tetrodotoxin and 30 mM tetraethyl ammonium bromide were also added to the solution. In *a* and *b* the fibres were stimulated by passing depolarising current pulses of 1 ms duration through the dye pipette. In *c* the fibre was voltage clamped, and stimulated by a 10-ms duration depolarising command pulse. Temperature: *a*, 29 °C; *b*, *c*, 7 °C.

record sensitive to Ca^{2+}-dependent changes in absorption of the dye, but in which movement artefacts were reduced.

When a fibre was depolarised to potentials above 0 mV, there was a definite latency between the rise in membrane potential and the onset of the Ca^{2+} response (Fig. 1 and refs 6, 8). This delay increased with decreasing temperature and was similar when the response was elicited by a depolarising pulse after blocking the action potential mechanism with tetrodotoxin, rather than by an action potential. For example, in 12 mM Ca^{2+} Ringer's solution, mean values of the delay-following action potentials and depolarising pulses were, respectively, 1.5 ± 0.2 ms (8) and 1.45 ± 0.42 ms (6) at a temperature of 15–16 °C, and 2.6 ± 0.8 ms (7) and 3.0 ± 0.6 ms (6) at 3–4 °C [mean, s.d. (number of fibres)]. Figure 2 shows the temperature dependence of the delay following an action potential, measured in muscle fibres bathed in Ringer's solutions containing various Ca^{2+} concentrations. The latency increased exponentially with the inverse of the absolute temperature (K) in all conditions studied, but at each Ca^{2+} concentration the slope of the relationship changed at a particular temperature. This transition temperature increased with increasing external Ca^{2+} concentration, and was 11 °C in 0 mM Ca^{2+}, 15 °C in 1.8 mM Ca^{2+} and 19.5 °C in 12 mM Ca^{2+}. This effect of Ca^{2+} concentration is probably specific to Ca^{2+} ions and not simply due to a change in divalent cation concentration, as the 0 Ca^{2+} solution contained 5 mM Mg^{2+}.

Another parameter of the excitation–contraction coupling system which displayed a similar temperature dependence to the initial latency, was the time during which a depolarised fibre could maintain an elevated Ca^{2+} level. Figure 3*a* shows a typical light absorbance record from a voltage-clamped fibre which was depolarised from −80 mV to +20 mV for 10 s. An initial large Ca^{2+} response was recorded which declined to the baseline over the duration of the pulse. Figure 3*b* shows an Arrhenius plot of the temperature dependence of the half-duration of this response, measured in a muscle bathed in 0 mM Ca^{2+} Ringer's solution. At temperatures below 11 °C the response half-duration remained constant at about 5.2 s, but at higher temperatures it decreased exponentially with the inverse of the absolute temperature. This transition temperature corresponds closely with that measured for the latency of the arsenazo signal during twitches on 0 mM Ca^{2+} solution. Technical difficulties prevented us from obtaining temperature dependence data at other Ca^{2+} concentrations, but at a temperature of 22.5 °C the response half-duration was slightly dependent on external Ca^{2+} concentration. Mean half-durations were 0 mM Ca^{2+}, 2.8 s (s.e.m. 0.14); 1.8 mM Ca^{2+}, 3.22 s (0.08); 12 mM Ca^{2+}, 3.8 s (0.12). This contrasts with frog slow muscle fibres, in which the duration of the maintained Ca^{2+} response is more strongly dependent on external Ca^{2+} concentration[9]. The peak sizes of the responses were not significantly affected by changes in temperature, suggesting that the shorter duration of the maintained Ca^{2+} response at high temperatures was not the result of exhaustion of Ca^{2+} reserves due to a higher rate of release. This agrees with the view that the amount of Ca^{2+} released during a prolonged depolarisation is controlled by a time-dependent inactivation of the release process[21,22].

Possible sources of the latency of the Ca^{2+} response include (1) response time of the dye, and diffusion time of Ca^{2+} within the myoplasm; (2) propagation time of the action potential inwards along the T-system; (3) a delay in the coupling mechanism between T-tubule depolarisation and Ca^{2+} release from the sarcoplasmic reticulum. The response time of arsenazo III is reported as faster than 400 μs at 21 °C (ref. 5) and the complex temperature dependence of the response latency makes it unlikely that the factors in (1) can account for the delay. Active propagation along the T-tubules has a velocity of about 7 cm s^{-1} at 7 °C in frog twitch fibres[10], and would therefore introduce a delay of about 1 ms for conduction to the centre of a

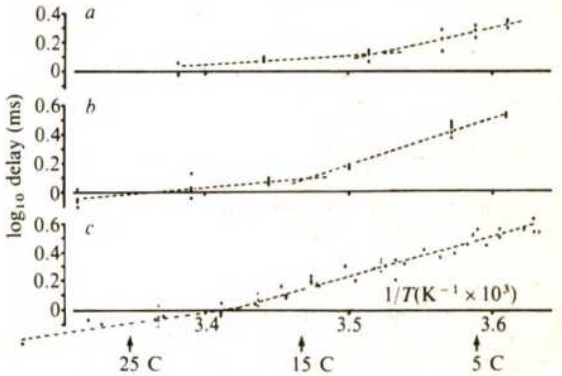

Fig. 2 Arrhenius plots of the log delay of the Ca^{2+} response against T^{-1}. The delay was measured by eliciting action potentials by a 1-ms depolarising pulse applied through the dye pipette, and measuring the latency between the foot of the action potential (about −40 mV) and the onset of the Ca^{2+} response (see Fig. 1). The three graphs show data from muscles bathed in Ringer's solution containing: *a*, 0 mM Ca^{2+} + 1 mM EGTA and 5 mM $MgCl_2$; *b*, 1.8 mM Ca^{2+}; *c*, 12 mM Ca^{2+}. A different muscle was used for each solution, and results from two muscles (●, and +) are shown in *c*. Each datum point was obtained from a different fibre, and is a mean of nine measurements. Readings were generally obtained from three or four fibres while holding the muscle at a given temperature, and different temperatures were tested in random order. Optical recording time constant was 0.5 ms. The lines drawn through the data were fitted by eye.

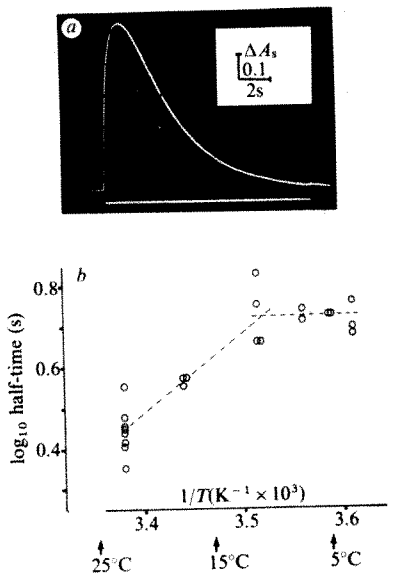

Fig. 3 *a*, Optical record showing the Ca^{2+}-induced change in differential light absorbance at 532–602 mn of an arsenazo III-loaded fibre, in response to a prolonged depolarisation. The fibre was voltage clamped to a potential of −80 mV at rest, and depolarised to +20 mV for the duration indicated by the bar. The vertical calibration, ΔA_s, gives the standardised change in light absorbance[3,6]. Ringer's solution contained 12 mM Ca^{2+}; temperature 5 °C; recording time constant 33 ms. *b*, Arrhenius plot of the log half-duration of the Ca^{2+} response during prolonged depolarisation. The half-duration was measured as the time for which the light absorbance record exceeded a value of one-half of the peak value. Each point is a single measurement from a different fibre from one muscle. Same experiment as Figs 2*a* and 3*a*.

100-μm fibre. However, the initial rise in the Ca^{2+} response probably results from activation of the sarcoplasmic reticulum at the periphery of the fibre, so that inward conduction time would not be an important factor in determining the minimal delay. A large part of the observed latency may therefore be attributed to the coupling mechanism.

The two component Arrhenius plots shown in Figs 1 and 2 resemble recent results on the elementary properties of drug receptor channels in muscle cells[11–15]. Possible causes of these temperature transitions include a membrane lipid phase transition[16–18], a conformational change in some protein[19] associated with the excitation–contraction coupling process, or different steps of a reaction sequence in the coupling process, being rate limiting in different parts of the temperature range[20]. Whatever the explanation, the influence of external Ca^{2+} concentration on the transition temperature of the latency in the rise of internal Ca^{2+} during a twitch, suggests that a delay in excitation–contraction coupling is introduced by a structure which is influenced by changes in Ca^{2+} concentration in the bathing medium, and is therefore probably located in the T-tubule membrane. The close similarity of transition temperature, and dependence on extracellular Ca^{2+}, of the duration of maintained Ca^{2+} response further suggests that this is also regulated by a structure in the T-tubule membrane[21,22].

Inhomogeneous distribution of filipin–sterol complexes in smooth muscle cell plasma membrane

THE plasma membrane of the smooth muscle cell presents characteristic rows of micro-invaginations or caveolae arranged parallel to the longitudinal axis of the cell[1–4]. Previous studies have demonstrated that the plasma membrane in the rows contains a much higher density of intramembranous particles than the intervening membrane zones[2,4]. The polyene antibiotic, filipin, by specifically interacting with cholesterol[5–7], produces distinctive alterations in freeze-fractured membranes[8–11], and the addition of filipin to aldehyde fixatives has been recently introduced as a cytochemical technique for the freeze-fracture localisation of cholesterol in cell membranes[12,13]. By applying this technique to smooth muscle cells, we have now obtained morphological evidence that the invaginated, particle-rich bands of the plasma membrane react with filipin to a far greater extent than does the non-invaginated membrane. The two membrane zones may thus differ in cholesterol content.

Strips of smooth muscle from rat large intestine were fixed in 2.5% glutaraldehyde in 0.1 M cacodylate buffer, *p*H 7.4, for 1 h, and incubated overnight at room temperature in the same fixative containing 300 μM filipin (Upjohn) dissolved in a drop of dimethyl sulphoxide (DMSO; final concentration 1%). Glutaraldehyde fixation is aimed at preserving cell ultrastructure by preventing the lysis resulting from filipin-induced permeability

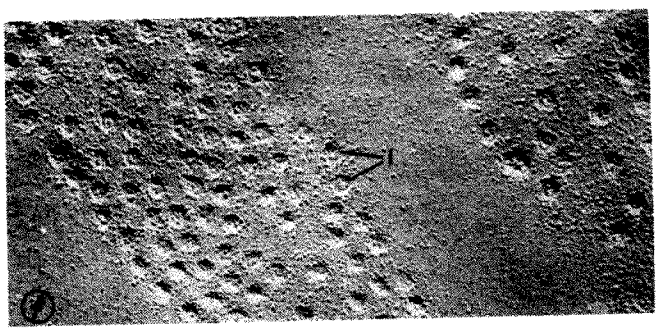

Fig. 1 Freeze-fracture replica of a smooth muscle cell fixed in glutaraldehyde alone. The plasma membrane of the cell has been split to reveal the protoplasmic leaflet or P-face[14]. The latter presents two parallel rows of crater-like circular depressions (i) representing the fractured necks of microinvaginations or caveolae. The density of intramembranous particles is higher within the rows than in the intervening membrane. The encircled arrows indicate the direction of platinum-carbon evaporation. ×47,000.

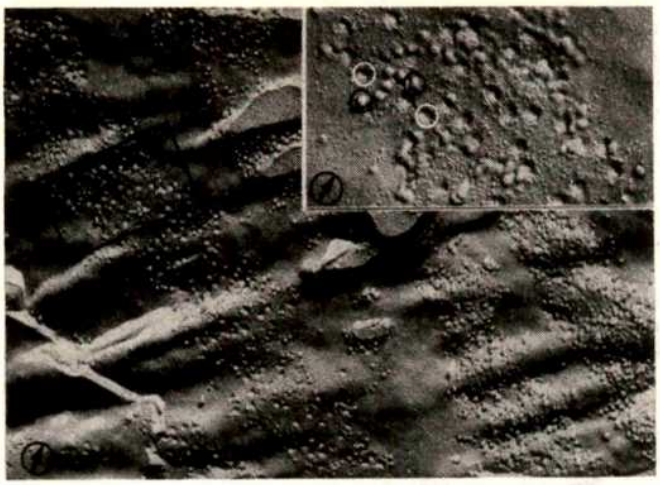

Fig. 2 Freeze-fracture replica of a smooth muscle cell fixed in glutaraldehyde-filipin mixture. The detail of a typical band of invaginations (black rectangle) is shown at high magnification in the inset. Numerous filipin–sterol complexes (black circles) are interspersed among the microinvaginations (white circles), whereas they are virtually absent outside the invaginated membrane regions. Filipin–sterol complexes appear as 25–30 nm protuberances which can be distinguished from the contiguous microinvaginations by the opposite polarity of platinum deposition (the direction of the shadowing is indicated by the encircled arrow). ×22,000. Inset: ×44,000.

changes in living cells[5]. Control muscle was fixed either in glutaraldehyde overnight, or in glutaraldehyde for 1 h and then in glutaraldehyde plus DMSO overnight. After rinsing in 0.1 M cacodylate buffer, *p*H 7.4, the tissues were cryoprotected with 30% glycerol in the same buffer, mounted on gold disks, and quickly frozen in Freon 22 cooled with liquid nitrogen. Fracturing and shadowing were carried out at −100 °C in Balzers BAF 300 and BAF 301 units. Replicas were cleaned by digestion in sodium hypochlorite, washed in distilled water, and recovered on coated 150-mesh copper grids. Freeze-fracture replicas were examined using a Philips EM 300 electron microscope.

Figure 1 illustrates the characteristic freeze-fracture appearance of the smooth muscle cell plasma membrane after aldehyde fixation alone[1–4]. The protoplasmic or P fracture face[14] shows many crater-like depressions, each one representing the fractured neck of an invagination. These craters are disposed in an orderly manner in parallel bands separated by regions of non-invaginated membrane. As has been previously observed[2,4], intramembranous particles are more numerous in the rows of invaginations. Fixation in glutaraldehyde plus 1% DMSO produces freeze-fracture images similar to those obtained with glutaraldehyde alone. When the smooth muscle is i in a filipin-containing glutaraldehyde solution, filipin–sterol complexes become recognisable as 25–30 nm protuberances[8–13] on the fractured plasma membranes (Fig. 2, inset). Filipin–sterol complexes are abundant in the particle-rich regions of the membrane, in which they are interspersed among the invaginations. By contrast, such complexes are virtually absent in the intercalated, particle-poor bands (Fig. 2). Due to the poor penetration of filipin within compact tissues, filipin–sterol complexes were usually confined to the most peripheral portions of the fractured specimens. Nevertheless, whenever found on a smooth muscle cell plasma membrane, they occurred with the selective distribution outlined above.

As filipin specifically binds to cholesterol and other related 3-β-hydroxysterols in cell membranes[6,7,15], our observation suggests heterogeneous distribution of these lipids in the smooth muscle cell plasma membrane. The functional significance of this heterogeneity is not clear, but it is worth noting that in the cells studied a higher sterol content is associated with both a higher density of intramembranous particles and morphological specialisation (invaginations) of the plasma membrane. It should be emphasised here that filipin labelling only represents qualitative evidence for sterol topographical inhomogeneity, and does not permit evaluation of the absolute sterol content of a discrete membrane region. In particular, the virtual lack of filipin reactivity in non-invaginated bands (which are the sites of insertion for actin myofilaments[16]) should not necessarily mean that there is no cholesterol there. In these membrane areas, the cholesterol level might be too low to induce the formation of detectable complexes to the same extent as found in invaginated regions.

The presence of a marked heterogeneity in sterol content between contiguous bands of membrane suggests that some restraint must exist in the lateral diffusion of cholesterol in the plane of the native membrane.

This study was supported by grant no. 3.120.77 from the Swiss National Science Foundation. I thank Drs A. Perrelet and L. Orci for encouragement and for revising the manuscript. Filipin was provided by Dr J. E. Grady of Upjohn, Kalamazoo.

Visualisation of ^{11}C-flunitrazepam displacement in the brain of the live baboon

THE presence of specific benzodiazepine receptors in the brain of rat[1,2], baboon[3] and man[4,5] has been demonstrated *in vitro*. These receptors have also been observed *in vivo* for diazepam[6] and flunitrazepam[7]. However in such experiments, although the radioactive ligand is injected in the living animal the demonstration of the presence of specific receptors requires brain tissue sampling for quantitative measurement *in vitro*. The fact that carbon-11 is a positron emitter with a half life of 20 min which can be used for very high specific activity labelling of drugs, raises the possibility of external detection of radioactivity in a living subject by positron emission tomography[8,9]. Using this new methodology the present study demonstrates the displacement of ^{11}C-flunitrazepam by lorazepam in the brain of live baboons.

Eight experiments were carried out with two female baboons (*Papio papio*) weighing 11 and 12 kg. After anaesthetisation with ketamine (15 mg per kg) the animals were intubated, ventilated and curarised by injection of nortoxiferin chlorhydrate (0.2 mg per kg as a starting dose followed by 0.1 mg per kg injections when necessary). At the end of the experiments the animals were decurarised using prostigmine. The interval between two experiments on the same animal was a minimum of 2 weeks. The animals were placed supine in a painless position under the positron camera (ECAT-ORTEC), the head inside a

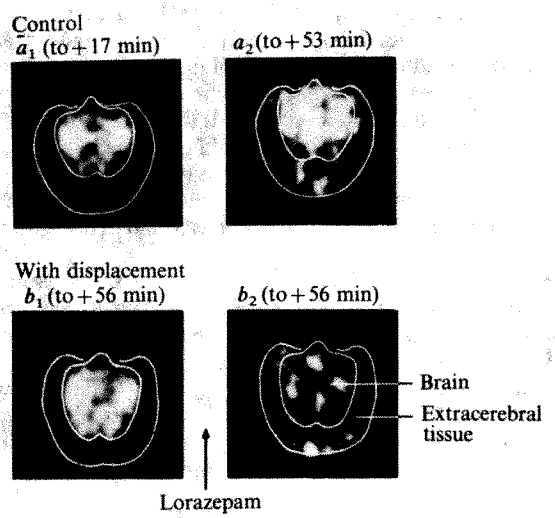

Fig. 1 Brain distribution at different times after i.v. injection of ^{11}C-flunitrazepam observed by positron emission tomography. Comparison of b_2 obtained 26 min after administration of a load of lorazepam (1.3 μM per kg) with a_2 (control experiment) reveals a displacement of the radioactive ligand. See Fig. 2 and Table 1 for quantitative data.

hammock in such a way that a 2-cm thick slice, parallel to and 2 cm above the inion orbital line, was observed by the camera. Flunitrazepam was labelled by ^{11}C-methyl iodide methylation of the nor derivative at a specific radioactivity of 300–900 Ci mmol^{-1} at the injection time[10]. The labelled drug (20–25 mCi), corresponding to 2–6 nM per kg weight, was injected intravenously (i.v.) at least 5 h after the ketamine anaesthesia, and the head scans were repeated over 1 h. Arterial blood and expired air samples were taken at given times to measure the radioactivity. In four experiments, lorazepam (1.3 μM per kg) was injected i.v. 30 min after ^{11}C-flunitrazepam to displace the radioactive tracer from the specific receptors. This benzodiazepine was used because of its high capacity to displace flunitrazepam from its specific binding sites[4]. The scans were visualised on a TV monitor and two regions of interest corresponding to cerebral and extracerebral tissues were selected. Quantitative data were obtained by comparing the '*in vivo*' activity with that of a control containing a known amount of radioactivity. Results in brain extracerebral tissues and blood were expressed as a percentage of the injected dose per g of tissue. Expired $^{11}CO_2$ activity was expressed as percentage injected dose. Blood pressure was recorded in some experiments by catheterisation of the femoral artery.

Figure 1 gives the pictures corresponding to one control (a) and one displacement experiment (b). Pictures a_1 and b_1 were obtained 17 and 20 min after ^{11}C-flunitrazepam injection. They show a high uptake of the labelled drug in the brain as compared with the extracerebral tissue, which cannot be seen on these pictures. On the other hand, 53 min after the tracer injection in the control experiment (a_2) the brain activity is still high but has decreased more rapidly than the extracerebral radioactivity, which is now visible. More important is the difference seen in b_2 taken at 56 min, 26 min after lorazepam injection. The contrast between brain and extracerebral tissue is less in this picture than in a_2. Figure 2 illustrates the kinetics of ^{11}C-flunitrazepam with and without displacement. In the control experiment the brain radioactivity curve (corrected for physical decay of ^{11}C) shows a sharp decrease during the first 20 min, followed by a more slowly decreasing phase during the next 30 min. In the displacement study lorazepam was injected at the beginning of the low-slope phase of the activity curve and led to a faster brain activity decrease than in the control. By contrast, extracerebral activity remained nearly constant throughout the experiment. Blood activity increased slightly after lorazepam injection.

Table 1 gives the data obtained in four control and four displacement studies. For each experiment the specific radioactivity (when measured) of the ligand at the time of injection, the cerebral, extracerebral, blood and expired $^{11}CO_2$ activities at the end of the experiment (50–60 min) are indicated. In all tests the extracerebral and blood activities are of the same order of magnitude, unlike that of the brain which is significantly lower after displacement. The presence of $^{11}CO_2$ in expired air indicates a demethylation of the radioactive ligand.

Modifications in the brain kinetics of high specific activity ^{11}C-flunitrazepam were definitely observed when a load of lorazepam was injected. The amount of radioactive ligand administered (2–6 nM per kg) is of the same order of magnitude as that used by other authors for displacement studies '*in vivo*' (ref. 7). Because of the low efficiency of radioactivity detection by external counting on the live animal, the specific radioactivity of the ligand had to be much higher than is generally used for '*in vitro*' measurements with tritiated molecules. Although theoretically a specific activity of 10^4 Ci μmol^{-1} can be reached when labelling with carbon-11, the best value obtained so far did not exceed 0.8–1.0 Ci μmol^{-1} at the time of injection[10]. A variation in displacement for different anatomical areas could not be observed because of the resolution (12 mm) of the positron camera. Furthermore, the thickness of the slice in the field of view of the detector is 20 mm. In these technical conditions it is difficult in a baboon's brain to differentiate the cortex, in which the density of receptors is high, from the other structures where the concentration is lower.

Chang *et al.*[7] have shown that after i.v. injection of ^{3}H-flunitrazepam only that fraction of the ligand bound to membranes is likely to be displaceable. Although bound and free fractions can be separated *in vitro* this is not the case *in vivo*

Table 1 Results of control and displacement studies of ^{11}C-flunitrazepam

	Specific activity (Ci mmol^{-1})	Brain uptake (% per g × 10^4)	Extracerebral uptake (% per g × 10^4)	Brain to extracerebral uptake ratio	Blood (% per g × 10^4)	Expired $^{11}CO_2$ (% in first hour)
Controls						
1	—	75	58	1.29	—	—
2	650	75	47	1.60	—	—
3	300	100	55	1.80	60	3.2
4	880	120	60	2.0	80	13
Mean ± s.d.	610	93 ± 22	55 ± 6	1.67 ± 0.3	—	
After displacement						
1	500	45	45	1.0	50	—
2	—	60	50	1.20	50	10.8
3	570	70	60	1.15	70	13.6
4	620	70	65	1.10	60	9.6
Mean ± s.d.	563	61 ± 12	55 ± 9	1.11 ± 0.09	58 ± 9.6	

Specific activity is given at the time of ^{11}C-flunitrazepam injection. Values are given as a percentage of the dose 50–60 min after injection of the radioactive ligand (20–25 mCi). In displacement studies lorazepam (1.3 μM per kg) was injected 30 min after ^{11}C-flunitrazepam. The average brain to extracerebral tissue uptake ratio was significantly lower (at the 2% level) after lorazepam injection and shows an apparent 35% displacement.

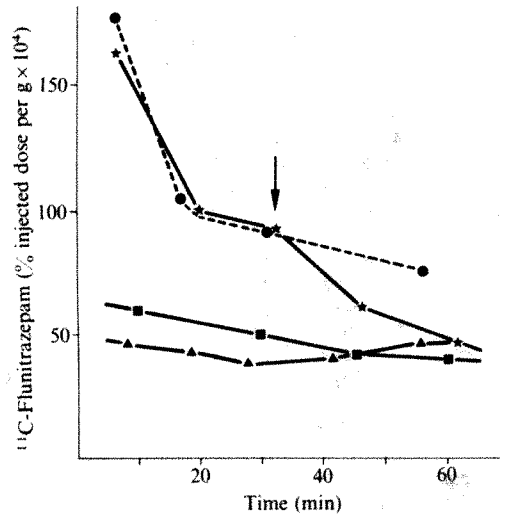

Fig. 2 ^{11}C-Flunitrazepam kinetics. ●, Cerebral uptake in a control experiment. ★, Cerebral uptake in a displacement experiment. Lorazepam (1.3 μM per kg) was injected (arrow) 30 min after ^{11}C-flunitrazepam. ■, Extracerebral uptake of the displacement experiment. The region measured is shown in Fig. 1. ▲, Blood in the displacement study.

and only the overall activity is measurable, giving an apparent displacement lower than observable when measured *in vitro*. Other physiological parameters, such as blood pressure and blood flow change after administration of a therapeutic dose of lorazepam, redistribution of the tracer in other organs which might modify its availability for brain tissue and the metabolism of the labelled drug itself with loss of the tracer by demethylation, might affect the amplitude of the displacement. In our experiments no modification of arterial blood pressure was observed. A redistribution of the radioactive ligand after displacement can be suspected as a slight increase in blood radioactivity following lorazepam injection was observed in all cases. However, this increase did not modify the extracerebral tissue uptake. Demethylation of the tracer was a significant feature, being variable from one experiment to another. As the *N*-demethylated product, which is not detected, has a pharmacological activity comparable with that of the parent compound, its possible binding to the same specific receptors will contribute to an underestimation of the observed displacement. Because of these points, an accurate quantification of the effect of a pharmacological dose of drug on the displacement of a radioactive ligand is more difficult *in vivo* than *in vitro*. However the data observed in this study correlate well with *in vitro* or semi-'*in vivo*' experiments. An apparent 35% displacement of ^{11}C-flunitrazepam by 1.3 μM per kg lorazepam agrees well with the ID_{50} values of Chang and Snyder[7] for clonazepam, flunitrazepam and diazepam in mice. The rapidity with which the displacement is observed, as shown in Fig. 2, corresponds well to the rapid anti-epileptic activity of the benzodiazepines.

These first results indicate that benzodiazepine brain receptors are detected in the live baboon in a non-traumatic way and that the methodology described may be applied to human beings for whom the detector used is better adapted than for animals. The development of new labelling methods with the short-lived radioisotope carbon-11 might also permit the detection in the living brain of other specific receptors and the evaluation of their properties as a function of pharmacological and physiopathological changes.

We thank Mrs M. Crouzel for technical assistance and Roche and Wyeth-Byla for providing flunitrazepam and lorazepam.

Partial agonists for brain GABA/benzodiazepine receptor complex

BENZODIAZEPINE receptors in the brain[1] are activated by γ-aminobutyric acid (GABA) and by the GABA agonist muscimol *in vitro*[2]. This activation may be related to the GABA-potentiating effects of benzodiazepines observed in electrophysiological studies (see ref. 3 for review). The enhancement of specific ^{3}H-diazepam binding by GABA agonists is inhibited by bicuculline and thus offers a unique high-affinity binding system for investigations *in vitro* of agonist–antagonist interactions at GABA receptors in the central nervous system. We report here that two GABA-mimetic compounds, 3-aminopropanesulphonic acid (APS) and isoguvacine, are partial agonists (mixed agonists/antagonists) with intermediate efficacies. Imidazoleacetic acid (IAA) is also a partial agonist but with only marginal agonist activity, and the new GABA-mimetics piperidine-4-sulphonic acid (PSA) and 4,5,6,7-tetrahydroisoxazolo-(5,4-*c*)pyridin-3-ol (THIP) are competitive antagonists to the GABA/benzodiazepine receptor complex.

One group of GABA agonists increases ^{3}H-diazepam binding to rat brain membranes, prepared as described in Fig. 1 legend. Muscimol (EC_{50} = 0.6 μM, see Fig. 2 legend), dihydromuscimol (1.9 μM), GABA (3.8 μM), thiomuscimol (4.2 μM), *trans*-aminocrotonic acid (7.4 μM), (*S*)(−)5-methylmuscimol (230 μM), (*R*)(+)4-methyl-GABA (410 μM), (*S*)(−)4-methyl-GABA (550 μM), and (*R*)(+)5-methylmuscimol (2,300 μM) increased specific ^{3}H-diazepam binding to ~200% of the control level[4] (because of limited supply of the latter three compounds the dose–response curves were stopped before maximal effect was achieved). The EC_{50} values for the nine agonists above as well as for 3-hydroxy-GABA and 3-guanidinopropionic acid[5] are closely correlated with inhibitory activity on ^{3}H-GABA binding sites. The EC_{50} values for benzodiazepine receptor activation, however, were 179 ± 32-fold higher than the respective IC_{50} values for ^{3}H-GABA binding[4,6,7] (mean ± s.e.m. for nine GABA agonists).

Thus three lines of evidence indicate that GABA receptors are involved in the increase in ^{3}H-diazepam binding: (1) The GABA antagonist bicuculline selectively and completely abolishes the activation induced by muscimol (Fig. 1*a* and refs 2, 5, 8, 9) and by the eight other agonists described above (data not shown). Bicuculline alone has no effect on this membrane system. (2) The activation of ^{3}H-diazepam binding is stereoselective for GABA agonists (data above) and highly correlated to the affinity of these same agonists for GABA receptors.

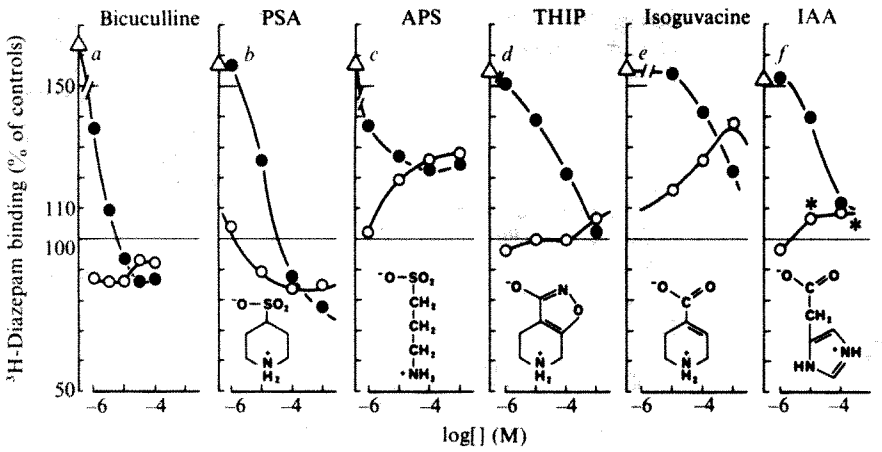

Fig. 1 Effects of bicuculline and some potent GABA-mimetics on ^{3}H-diazepam binding to rat brain membranes. ○, GABA-mimetic alone; ●, GABA-mimetic plus 3×10^{-6} M muscimol; △, muscimol alone, 3×10^{-6} M. Whole rat forebrains were homogenised in 10 vol ice-cold 100 mM Tris-citrate *p*H 7.1, in a precooled Ultra-Turrax homogeniser. The homogenate was centrifuged at 48,000*g* for 10 min at 0–4 °C and the pellet was rehomogenised for a few seconds in another 10 vol of the same ice-cold buffer. Centrifugation and rehomogenisation were performed five times. The final suspension was diluted to 160 vol (vol/weight original tissue) in 100 mM Tris-citrate *p*H 7.1, and aliquots of 2.5 ml were incubated with 0.4 nM ^{3}H-diazepam (14.4 Ci mmol^{-1}, gift from Willy Haefely, Roche) for 20 min at 0 °C in a total of 2.75 ml. GABA antagonists and agonists were added in duplicate in that order just before ^{3}H-diazepam. Samples were diluted to 10 ml in cold buffer after incubation and filtered immediately through GF/C glass-fibre filters and washed with 10 ml buffer. Tritium on filters was assessed by scintillation counting. All binding values were calculated as specific binding, which is total binding minus binding in the presence of 3×10^{-6} M unlabelled diazepam. Control specific binding averaged 677 ± 49 c.p.m. per 15 mg tissue; specific binding in the presence of 3×10^{-6} M muscimol, 1,037 ± 70 c.p.m. per 15 mg tissue; and nonspecific binding 157 ± 15 c.p.m. per 15 mg tissue (mean ± s.e.m. of six experiments). The data shown are from a single experiment which was repeated giving similar results. Bicuculline (Sigma) was freshly prepared in dilute HCl; piperidine-4-sulphonic acid and THIP, H_2O were synthesised by P.K.-L.; APS (sodium salt) was supplied by J. Arnt, Copenhagen; isoguvacine, HCl was synthesised by O. Rosenlund-Hansen, Ferrosan. * Imidazoleacetic acid (10^{-5}–10^{-4} M) increased ^{3}H-diazepam binding (17.6 ± 2.04% in six experiments, $P<0.001$).

Activation of benzodiazepine receptors by GABA is achieved at micromolar concentrations, as are GABA effects on the superior cervical ganglion[10], the cuneate nucleus *in vitro*[11], the crayfish stretch receptor neurone[12] and the dorsal root ganglion neurone[13]. (3) The only non-GABA-agonist (potassium iodide, 30 mM, see also ref. 14) among many tested which increased ^{3}H-diazepam binding in the present membrane preparation acts in an additive way to muscimol, suggesting a different mechanism of action[4].

A second group of potent GABA-mimetics, piperidine-4-sulphonic acid, APS, IAA, THIP and isoguvacine (see below) did not, however, increase ^{3}H-diazepam binding to any great extent (Fig. 1*b–f*), even at concentrations more than 10,000-fold in excess of the respective IC_{50} values[6,7] for ^{3}H-GABA binding (see also refs 2, 15). These compounds surprisingly inhibited muscimol activation to a degree depending on their respective efficacies (Fig. 1*b–f*). Piperidine-4-sulphonic acid also completely inhibited the activation induced by *trans*-aminocrotonic acid and GABA. GABA analogues of restricted conformation (isomuscimol, iso-THIP and homologues of THIP with seven-membered heterocyclic rings[6]) were inactive as inhibitors of ^{3}H-GABA binding, as activators of ^{3}H-diazepam binding and as inhibitors of muscimol activation.

Parallel displacement of dose–response curves for muscimol and linear Schild plots with slopes close to unity (Fig. 2) indicate that piperidine-4-sulphonic acid is a competitive inhibitor of muscimol in a first-order interaction. If piperidine-4-sulphonic acid had been a pure agonist to GABA receptors, an EC_{50} value of $179\times IC_{50} = 7.1$ μM would be expected ($IC_{50} = 40$ nM for ^{3}H-GABA binding, P.K.-L. unpublished). The antagonist affinity, $K_I = 1.5$ μM (Fig. 2*b*), is relatively close to this predicted value, indicating that piperidine-4-sulphonic acid occupies GABA receptors with the expected affinity but without efficacy in the present system. Piperidine-4-sulphonic acid and THIP are antagonists in the present membrane preparation (washed membranes). Partial agonist properties cannot be excluded since both compounds exhibit marginal agonistic effects in Triton-treated membranes[4].

Piperidine-4-sulphonic acid (P.K.-L., D. R. Curtis and E.F. unpublished), APS[16], IAA[6,17], THIP[6,18] and isoguvacine[6,18] are GABA-mimetic in the sense that they inhibit high-affinity GABA receptor binding with IC_{50} values ranging from 6 to 130 nM, and that they are potent bicuculline-sensitive inhibitors of cat spinal cord motoneurones. However, when tested on the coupled GABA-receptor benzodiazepine receptor *in vitro*, these compounds exhibit mixed agonist/antagonist or pure antagonist properties. The physiological relevance of this feature is unclear, but the finding that APS is less active on crayfish stretch receptor neurones than expected from receptor binding studies[19], and the unexpected lack of GABA-like activity of THIP and isoguvacine on E4 cells in the visceral ganglion of *Helix aspersa*[20] may be a consequence of low efficacy.

It is thus conceivable that several classes of GABA receptors exist in the central nervous system; some (those coupled to benzodiazepine receptors) may differentiate a continuum of pure and partial agonists, whereas other classes possess no such selectivity.

The experiments described here introduce a simple technique for studying 'classical' pharmacology in the central nervous system. Other high-affinity binding sites may be coupled, making the principle more generally applicable.

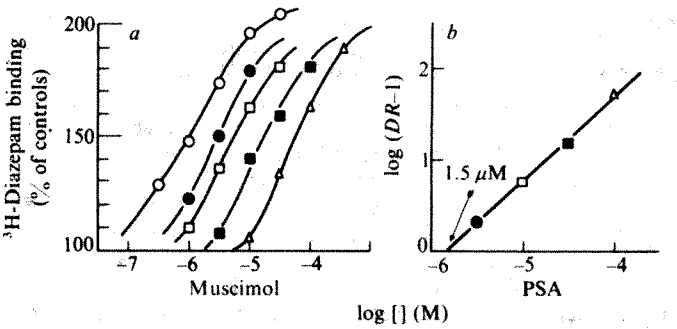

Fig. 2 *a*, Dose–response curves for the effect of muscimol on ^{3}H-diazepam binding to rat brain membranes prepared as described in Fig. 1. Various concentrations of piperidine-4-sulphonic acid were added. ○, No addition; ●, 3×10^{-6} M; □, 10^{-5} M; ■, 3×10^{-5} M; △, 10^{-4} M. *b*, Schild plots constructed from the EC_{50} values for muscimol obtained in *a*. (The dose–response ratio, *DR*, is the ratio of EC_{50} values for muscimol with and without antagonist added.) Slope in *b*, 0.92. The EC_{50} value is that concentration of GABA agonist in μM which increases specific ^{3}H-diazepam binding to half the maximal increase obtainable with optimal concentrations (10^{-5}–3×10^{-5} M) of muscimol. EC_{50} values given are means of at least two values, each obtained by Hill analysis of results obtained by addition of four to ten concentrations of agonist in duplicate assays. The results shown in this figure are from a single experiment which was repeated twice with similar results. Each point in *a* is the mean of two values which differed 2.7 ± 0.5% (25); the control level was 784 ± 15 c.p.m. per 15 mg tissue (9) (mean ± s.e.m. of (*n*) values).

We thank Mrs A. Vestergaard for technical assistance. This study was supported by grants Jr. N. 512-8404 and 512-8405 from the Danish MRC.

Solvent accessibility properties of complex proteins

AN important factor in the thermodynamics of protein folding is the partition of amino acid residues between the solvent environment and the protein core. The extent of the interaction between the folded polypeptide and the surrounding medium can be measured by determining the solvent accessible surface area as defined by Lee and Richards[1]. In this communication we present the results of solvent accessibility calculations for the large (195,000 M_r) dimeric enzyme phosphorylase *a* and other multidomain, multisubunit proteins. These results are discussed in the light of the generalisations concerning protein solvent—accessible surface area and shape which have been based on data derived from low molecular weight proteins.

X-ray diffraction studies of proteins have, in many cases, provided atomic coordinates of sufficient accuracy to make accessibility calculations feasible. Using the crystallographically-derived coordinates for a select group of small ($M_r \leq$ 30,000), compact, well determined protein structures, Janin[2] and Teller[3] have demonstrated that the solvent-accessible surface area, A_s, can be expressed as a function of molecular weight:

$$A_s = 11.1\, M^{2/3} \qquad (1)$$

The standard error between calculated and theoretical values of A_s, for structures incorporated in the data base is about 400 Å^2 (ref. 3). This model predicts that protein molecules adopt a globular shape for which the surface area/volume ratio approaches the minimum value characteristic of a sphere. (It is not implied that proteins are necessarily spherical.) Interpenetrating spherical surfaces have been used to model the accessible surface changes in the dimerisation of insulin, the interaction between haemoglobin α and β subunits and of trypsin with its inhibitor[3].

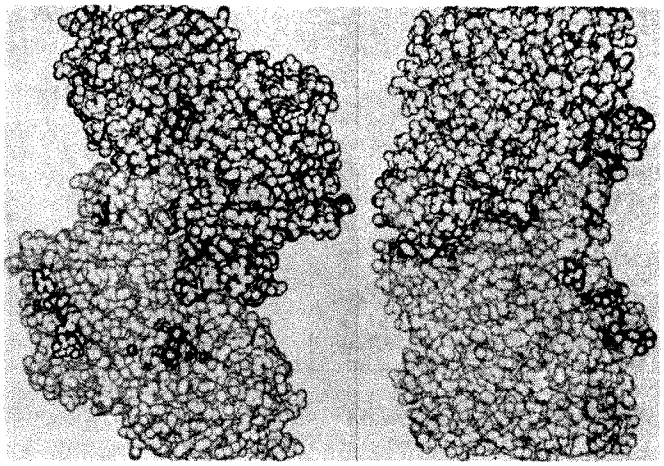

Fig. 1 Two orthogonal views of the Van der Waal's contact surface of the phosphorylase *a* dimer. All nonhydrogen atoms at the surface are shown as well as several ligands which bind to the enzyme: S, maltoheptaose; G, a buried glucose molecule; C, caffeine; plp, the buried coenzyme pyridoxal phosphate; P, the serine-14-phosphate and A, AMP. The atomic positions were determined by X-ray diffraction at 2.5 Å resolution. The two subunits are shown in different shades of grey. Note that although the dimer contact appears to be extensive in these drawings, a large solvent accessible cavity of about 2,500 Å^3 lies at the subunit interface. The left plate shows the face of the dimer that binds to glycogen[11]. This same face is seen edge-on at the right in the orthogonal view.

Using an extended data base, Janin[4] has recently shown that the number of buried ($A_s < 20$ Å^2 per residue) amino acids, n_B, in a protein of n residues is given by

$$n_B = (n^{1/3} - k)^3 \qquad (2)$$

where $k = 1.62$.

As many proteins of biological interest are large, multidomain and oligomeric, it is of interest to determine the applicability of models based on simpler structures to these more complex systems. We have recently determined the atomic coordinate set for rabbit muscle phosphorylase *a* (ref. 5). This protein has about three times more amino acids per polypeptide chain than the largest used to determine the accessibility law. Further, phosphorylase occurs as a dimer in the tetragonal crystal form discussed here, allowing a determination of the protein surface removed from solvent contact by dimerisation. Using a program written by T. J. Richmond, incorporating the algorithm of Lee and Richards[1], we have calculated the solvent-accessible surface areas for monomers and dimers of phosphorylase *a*, chicken triose phosphate isomerase (TIM), horse alcohol dehydrogenase (ADH), human Bence–Jones protein (BJ) and the monomer and tetramer of dogfish apolactate dehydrogenase (LDH). Atomic coordinates were obtained from the AMSOM protein data files[6]. Accessible surface areas and related parameters are summarised and described in Table 1. The data for insulin and the haemoglobin α and β chains given by Chothia and Janin[9], which agree with our calculations for these cases, are included for comparison.

It seems that expression (1) holds well for low molecular weight protein monomers. However, for larger proteins, the model underestimates accessible surface area by a margin of error which increases with the molecular weight of the monomer. This discrepancy has already been noted for oligomeric proteins[3,4]. The model errs most seriously with phosphorylase.

* Derived quantities: A_s^{th}, solvent accessibility calculated from equation (1); for dimers and the tetramer of LDH accessible surface area is given by the expression $2\times(0.86\ A_s^{th})$ and $4\times(0.72\ A_s^{th})$, respectively, where A_s^{th} is the surface area of the monomer[3]. F_{as}, the fraction of potentially accessible surface buried by protein folding is given by $(A_t - A_s^{obs})/A_t$ where $A_t(=1.44\ M)$ is the accessible area of an extended polypeptide chain[7]. n_B^{th} is the number of residues buried by protein folding predicted by equation (2). F_B^{obs} and F_B^{th} are the observed and predicted[3] values for solvent-accessible surface area buried at the dimer or tetramer interface.

† Reproduced from ref. 3.

The expression proposed to predict n_B (equation (2)) is reasonably accurate for most of the cases listed in Table 1 (only monomers are considered), but does not apply for monomers of LDH and phosphorylase. The sphere interpenetration model for dimerisation predicts that approximately 14% and 28% of the monomer surface is buried after the formation of dimers and square planar tetramers, respectively[3]. It is interesting that theoretical values of A_s for the TIM dimer and the LDH tetramer prove to be more accurate predictions than the theoretical values of A_s for the isolated monomers. A minimum surface model seems to fit the oligomers better than their respective monomers. Phosphorylase is again a notable exception. Only 6% of the accessible surface of the monomer (2,300 Å^2) is involved in dimer formation. This analysis does not account for possible conformational changes on oligomerisation (see below).

Although minor deviations in observed A_s and n_B from values predicted by equations (1) and (2) may be attributed to non-spherical shape, this explanation cannot account for the significant underestimation for phosphorylase. For example, one can readily show that a parallelepiped of dimensions sufficient to completely enclose the phosphorylase monomer would have a surface area equal to that of the protein but would contain twice its volume. In fact, the large accessible areas of LDH, ADH and phosphorylase are most probably due to the articulation of each of these molecules into two well-defined functional and structural domains, which gives rise to a complex and invaginated molecular topography. This is illustrated in the space-filling model of the phosphorylase dimer (Fig. 1). Chothia[7] has suggested that in such large multidomain or multisubunit structures, the fraction of potentially accessible surface area buried by protein folding, F_{as}, is essentially constant. Table 1 shows that F_{as} for monomers and multimers becomes asymptotic at 0.75–0.78. This implies that the accessible surface becomes a linear function of M_r for large proteins. A plot of A_s against M_r from Table 1 shows this to be true.

Although only a small fraction of the phosphorylase molecule is involved in dimer formation, the amount of surface area withdrawn from solvent by formation of the complex is quite large, 4,600 Å^2. Loss of accessible surface area is believed to contribute significantly to the free energy of protein association[8,10] which may be expressed (for dissociation) as

$$\Delta H_d + \Delta G_d^l - \Delta G_d^s = \Delta G_d \qquad (3)$$

where ΔG_d^s and ΔG_d^l are free energy terms due, respectively, to the gain in rotational and translational entropy by the subunits upon dissociation and to the entropy lost by solvent as a result of the increase in subunit accessible area. The enthalpy of dissociation, ΔH_d, is assumed to be small[8,9] due to the energetic equivalence between solvent–monomer and monomer–monomer hydrogen bonds and Van der Waals' interactions. The free energy of dissociation, ΔG_d, is $-RT$ ln K_d. These parameters may be evaluated for the dissociation of the phosphorylase dimer.

Using the expression derived from statistical thermodynamics by Janin[10], ΔG_d^s is 33 kcal mol^{-1}. The hydrophobic free energy ΔG_d^l has been given as a direct function of the change in accessible surface area ($\gamma\Delta A_s$, where $\gamma \sim 25$ cal mol^{-1} Å^{-2})[8,9]. Assuming $\Delta A_s \sim 2A_s^{monomer} - A_s^{dimer}$, ΔG_d^l is approximately 155 kcal mol^{-1}. Substituting these values into equation (3), we arrive at the clearly unreasonable estimate of 82 kcal mol^{-1} ($K_d \sim 10^{-60}$) for ΔG_d. If only nonpolar atoms, that is, carbon atoms, are considered in the accessibility calculation, ΔA_s is about 2,600 Å^2, corresponding to ΔG_d of 33 kcal mol^{-1} ($K_d \sim 10^{-24}$). Preliminary kinetic studies (N.B. Madsen, personal communication) indicate ΔG_d for phosphorylase is probably about 11 kcal mol^{-1}.

It is unlikely that errors in the phosphorylase coordinate set can account for these discrepancies. One source of error could be the assumption that the subunit assumes the same conformation within the dimer as it does as a monomer. For example, the free monomer may bury a significant proportion of the accessible surface area which is also observed to be buried in the dimer. If this were indeed the case, we would conclude (assuming $\Delta H_d \sim 0$ and $\Delta G_d \sim 11$ kcal mol^{-1}) from equation (3) that ΔA_d is only 900 Å^2 per monomer. Another source of error could be the assumption of $\Delta H_d \simeq 0$. The enthalpy, if non-zero,

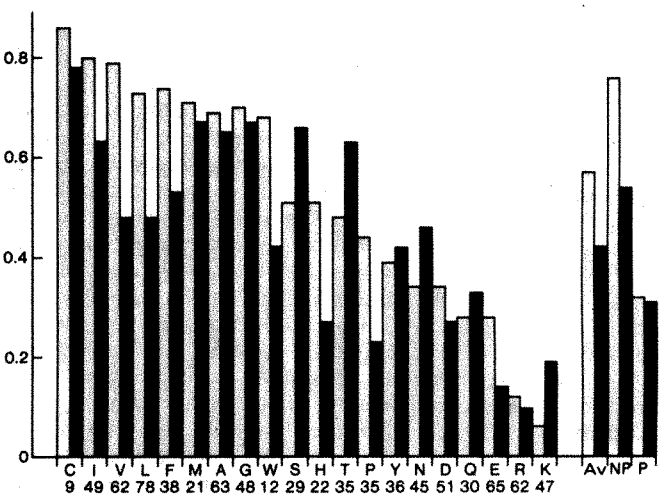

Fig. 2 The ordinate shows the mole-fraction buried for each type of amino acid and the distribution predicted using the partition coefficients determined by Janin[4]. The number of each type of amino acid is shown below the usual one letter code representation. The three additional entries at the right represent respectively the average over all amino acids (Av) the nonpolar amino acids (Ile, Val, Leu, Phe, Met, Ala, Trp, Gly, Pro; NP) and the polar amino acids (P).

could contain contributions from subunit association and/or subunit conformational changes.

As the bulk solvent accessibility properties of phosphorylase differ significantly from those predicted from smaller systems, it is of interest to note the relative accessibility of polar and nonpolar side chains. Chothia[2] has found that the proportion of non-polar surface buried increases with molecular weight, whereas the proportion of polar surface buried is constant. A similar conclusion is drawn from Janin's results[4]. Figure 2 shows the mole fraction buried for each of the amino acids in phosphorylase compared with that predicted for phosphorylase using partition coefficients determined by Janin[4] for each residue, and n_b as observed (357) (see Table 1 and equation (3) in this reference). Generally fewer of the nonpolar residues (Ile, Val, Leu, Phe, Trp and Pro) are buried in phosphorylase than predicted from the data base; the accessibility for the polar residues (Ser, Thr, Asn, Gln and Lys) is lower than predicted. (Note that there is relatively little difficulty with sample size in these statistics since only Trp and Cys appear fewer than 20 times.)

Accounting for these deviations from predicted accessible surface in the case of phosphorylase is difficult. It is unlikely on a biochemical basis that other macromolecules, for example, kinase, phosphatase and glycogen, bury additional surface *in vivo*. The most likely explanation for the discrepancy in accessible surface and the distribution of buried residues is that the data base used for deriving expression (1) rests on a small sample of mainly extracellular proteins of low molecular weight. These proteins are generally required by their environment to be structurally more stable than the large and conformationally labile intracellular regulatory proteins, such as phosphorylase. We feel that the closing statement of Lee and Richards' original paper[1] is still appropriate: "Simple generalisations of any sort are remarkably difficult to see in the summaries so far produced".

Evidence for non-spliced SV40 RNA in undifferentiated murine teratocarcinoma stem cells

UNDIFFERENTIATED murine teratocarcinoma stem cells do not support simian vacuolating virus 40 (SV40) or polyoma virus (Py) replication or even the expression of the early papovavirus proteins. These undifferentiated cells are also entirely refractory to infection with ecotropic murine C-type viruses. If the stem cells are allowed to differentiate to a variety of somatic cell types, they become susceptible to infection by SV40, Py and ecotopic murine C-type viruses[1–4]. In contrast, adenovirus type 2 can infect and replicate in the undifferentiated stem cells, although not as efficiently as it can in the differentiated mouse cells[5] and certainly much less efficiently than it does in human cells. Studies on the mechanism of the resistance of the undifferentiated teratocarcinoma cells to infection by SV40 has shown that the block is not at the level of virus adsorption, penetration uncoating or transport to the nucleus[6]. We present here evidence indicating that the absence of expression of SV40 genetic information in nondifferentiated teratocarcinoma cells reflects an inability to generate stable viral mRNA. More specifically, the refractoriness of these cells to SV40 seems to be correlated, at least in part, with a deficiency in the splicing of viral mRNA.

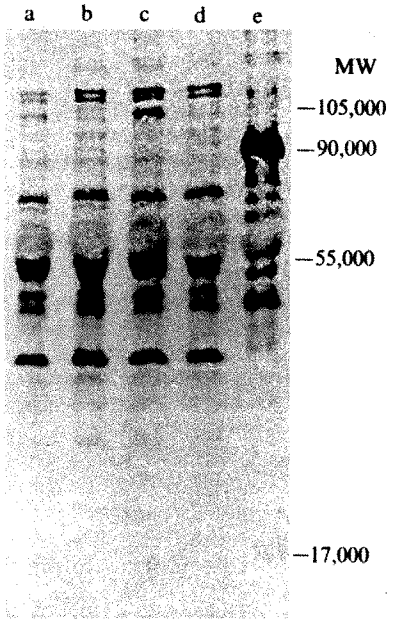

Fig. 1 Analysis of proteins in SV40-infected F-9 cells. Cultures of 1×10^7 F-9 cells uninfected or infected with SV40 (250 p.f.u. per cell) for 17 h, were labelled for 2 h with ^{35}S-methionine (100 μCi ml^{-1}) in methionine-free medium. Proteins were purified and immunoprecipitated with hamster anti-SV40 T-serum as described previously[10]. Samples were electrophoresed in 20% polyacrylamide slab gels (20% acrylamide–0.1% bisacrylamide) for 10 h at 75 V (ref. 11). The autoradiograph shows proteins extracted from uninfected F-9 cells immunoprecipitated with anti-SV40 T-serum (a); or with normal hamster serum (b); proteins extracted from SV40-infected F-9 cells immunoprecipitated with anti-SV40 T-serum (c); or with normal hamster serum (d); control proteins from SV40-infected AGMK cells immunoprecipitated with anti-SV40 T-serum (e).

The F-9 line of mouse teratocarcinoma cells, a nullipotent stem cell line that does not differentiate in normal culture conditions[7–9], was used. Cells were generally inoculated with high multiplicities of infection (MOI) of plaque-purified wild-type SV40 (50–250 plaque-forming units (p.f.u.) per cell). Although infection of differentiated mouse cells (for example primary mouse embryo or 3T3 cells) with SV40 does not lead to the synthesis of viral DNA or the production of late viral polypeptides, substantial amounts of SV40 large T- and small t-antigens and the early SV40 RNA which encodes these proteins can usually be detected. In contrast, others have shown that SV40 infection of undifferentiatiated teratocarcinoma cells does not result in detectable T-antigen synthesis[1], as assayed by immunofluorescence. To confirm this observation we examined the SV40-infected F-9 cells for SV40 antigens using the more sensitive technique of immunoprecipitation and polyacrylamide gel electrophoresis (PAGE). After labelling SV40-infected F-9 cells with ^{35}S-methionine 17 h post-infection (p.i.), proteins in the soluble extracts were immunoprecipitated either with a T-serum (obtained from hamsters bearing SV40 tumours), or with a control normal hamster serum[10]. The immunoprecipitated proteins were analysed on 20% polyacrylamide-SDS

gels[11]. As shown in Fig. 1c, SV40-infected F-9 cells do not synthesise either of the known early SV40 gene products (90,000-MW T-antigen and 17,000-MW t-antigen[12,13]). However, two distinct polypeptides with apparent molecular weights of 105,000 and 55,000 were immunoprecipitated with anti-SV40 T serum, both from the SV40-infected and from the uninfected F-9 cells (Fig. 1a,c). These two proteins were not seen in the control reactions with normal serum (Fig. 1b,d), suggesting that although anti-T serum has antibodies against the 105,000 and 55,000-MW proteins, these may not be encoded by SV40. Further analysis of these two proteins will be presented elsewhere. It has been previously shown[14,15] that an antiserum from rabbits which had been immunised with cells from the embryoid bodies of mouse teratocarcinomas contain several distinguishable antibody specificities, including an activity against Py- and SV40-transformed mouse fibroblast lines and a variety of mouse tumour cells. Our results suggest that the two immunoprecipitable proteins (105,000 and 55,000 MW) may represent common polypeptides synthesised in undifferentiated and SV40-transformed mouse cells. The significance and potential relationship of these proteins to tumorigenesis are being investigated.

As we were unable to detect SV40 T-antigens in the infected F-9 cells, we sought to determine whether the inoculated SV40 DNA was being transcribed. From previous studies[16] it was clear that the most sensitive assay for detection of viral transcription is the *in vitro* sarkosyl method[17]. This technique relies on the fact that viral transcriptional complexes (VTCs) which are initiated *in vivo* can be extended (but not initiated) *in vitro*; its sensitivity derives from: (1) the ability to incorporate high specific activity precursors into growing RNA chains; (2) removal of potential processing enzymes which could degrade 'unstable' RNA species; and (3) separation of the viral transcriptional activity in the sarkosyl supernatant fraction from the bulk of the cellular transcriptional activity which resides in the chromatin pellet. Ten hours after infection of F-9 cells (MOI = 250) VTCs were isolated and incubated in a standard reaction mixture[18] containing [α ^{32}P]ATP. (In a separate experiment (S.S., E. May and G.K., in preparation), 10 h p.i. was found to correspond to the peak of viral transcriptional activity in mouse cells.) RNA was purified and annealed with the separated strands of two SV40 DNA fragments (representing early and late regions of the viral genome) which had been immobilised on nitrocellulose filters[19] (Fig. 2). The pattern of hybridisation clearly indicates that viral transcription is initiated in SV40-infected F-9 cells. As the transcriptional activity can be detected in the supernatant fraction, this transcription seems to be initiated, at least in part, on free viral DNA molecules[18]. Finally, the ratio of early strand to late strand transcription (5.5 : 4.5), determined by a densitometric tracing of the autoradiograms, indicates that substantial fractions of viral transcription are initiated on both early and late viral DNA strands. Although it is difficult to quantitate the *in vitro* transcriptional activity specifically, similar amounts of virus-specific RNA have been obtained from VTCs of differentiated and undifferentiated mouse cells (S.S. *et al.*, in preparation).

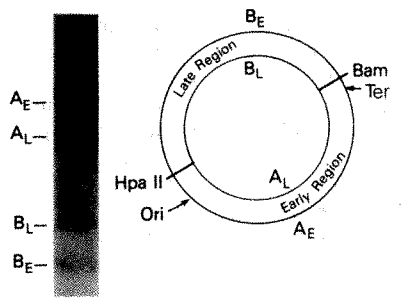

Fig. 2 Analysis of *in vitro*-extended RNA from SV40-infected F-9 cells. Viral transcriptional complexes (VTCs) were prepared using the sarkosyl extraction method[17] from the nuclei of SV40-infected F-9 cells 10 h after infection. After *in vitro* incorporation of [α-^{32}P]ATP (350 Ci mmol^{-1}) into the elongating RNA chains[16], RNA was isolated as previously described[18]. Strand orientation and genomic region of the RNA was determined by hybridisation to the separated strands of *Bam*HI/*Hpa*II-cleaved SV40 DNA immobilised on nitrocellulose filter[19]. Ori, origin of viral DNA replication; Ter, terminus of DNA replication (these sites divide SV40 into the early and late gene regions); A_E = SV40 early coding strand; B_E, early non-coding; B_L, late coding; A_L, late noncoding.

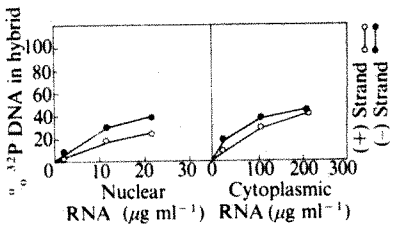

Fig. 3 Analysis of unlabelled *in vivo* viral RNA from SV40-infected F-9 cells. Nuclear and cytoplasmic RNAs were prepared from SV40-infected F-9 cells (250 p.f.u. per cell) 10 h p.i. as described elsewhere[23]. Increasing concentrations of RNA (cytoplasmic and nuclear) were hybridised for 20 h to fragmented ^{32}P-labelled separated single strands of SV40 DNA (specific activity, 1×10^6 c.p.m. μg^{-1}) in conditions previously described[27]; the fraction of SV40 L and E strands in hybrid molecules was determined by hydroxyapatite chromatography[20].

We consequently undertook a second set of experiments in an attempt to detect and characterise viral RNA transcribed *in vivo*. Unlabelled cytoplasmic and nuclear RNAs were purified 10 h after infection of F-9 cells. To determine the proportion of the SV40 genome that is transcribed *in vivo*, increasing concentrations of the cytoplasmic and nuclear RNAs were annealed in solution with separated strands of ^{32}P-labelled single-strand fragments of SV40 DNA. The fraction of each DNA strand in hybrid molecules was determined by hydroxyapatite chromatography[20]. As seen in Fig. 3, the extent of hybridisation between the (−)strand and (+)strand of SV40 DNA and increasing RNA concentrations was almost linear and did not reach a plateau. At the highest RNA concentration used, about 40% of the (−)strand and 20% of the (+)strand fragments appear in duplex molecules. This result supports the VTC study in showing that both early and late strands of SV40 are transcribed in F-9 cells, although the fraction of each strand represented in RNA is not established by this experiment. The paucity of stable SV40 RNAs in F-9 cells prompted a further analysis of these transcripts. As early SV40 RNA seems to be more abundant than late RNA in F-9 cells and only the early transcripts are translated into detectable virus-specific proteins in mouse embryo or 3T3 cells, we focused on an analysis of the early viral RNA. Berk and Sharp have recently introduced an alkaline agarose gel electrophoresis technique which can effectively size and map both co-linear and spliced RNA molecules[21]. ^{32}P-double-stranded DNA probes are annealed with RNA in conditions which favour DNA–RNA annealing. The hybrid species are treated with S_1 nuclease before electrophoresis and the labelled DNA, which can be accurately sized as single-stranded molecules, provides a direct representation of the RNA molecules present. This method has demonstrated the presence of two spliced early SV40 mRNAs which code for T and t antigens[22] (see Fig. 4*a*). We have recently found that the sensitivity of this technique can be amplified if one uses strand-separated DNA probes, thus permitting hybridisation in much less stringent conditions. This modification is crucial to an analysis of transcripts as scarce as those present in SV40-infected F-9 cells.

Both total RNA and cytoplasmic RNA were isolated 10 h after SV40 infection of either differentiated primary mouse embryo (ME) cells or the undifferentiated F-9 teratocarcinoma cells. The cytoplasmic ME and F-9 RNAs were further fractionated into poly(A)-containing (poly(A)$^+$) and non-poly(A)-containing (poly(A)$^-$) fractions. For a probe, ^{32}P-labelled SV40 DNA was cleaved with *Bam*HI and *Hpa*II restriction endonucleases and the early coding single strand of the DNA

fragment mapping from 0.145 to 0.725 (*Bam*HI/*Hp*II A_E) was purified[19] and hybridised with the RNAs described above. After annealing, hybrid molecules were digested with nuclease S_1 and the products were analysed by alkaline agarose gel electrophoresis.

In a control experiment (Fig. 4*a*), the S_1 technique was used to map early SV40 cytoplasmic RNAs from lytically infected monkey kidney (MK) cells. As expected, three bands were observed which measured 0.38, 0.12 and 0.065 SV40 map units. These represent the RNA body coding for T and t antigens, (0.38) and the (0.12) and (0.065) leader segments (Fig. 4*c*).

In contrast, (Fig. 4*b*) the hybridisation of nuclear or cytoplasmic early RNA from SV40-infected F-9 cells produced one band migrating at a position corresponding to 0.52 SV40 units length. This fragment has been positioned at between 0.67 and 0.15 map units and corresponds directly in size and map position with the primary early SV40 transcript found in the nuclei of SV40–infected MK cells (unpublished data). The analysis of RNA from SV40-infected differentiated primary mouse embryo cells is also shown in Fig. 4*b*. Total cellular RNA from SV40-infected ME cells produced two major bands, one corresponding to a non-spliced early SV40 transcript (0.52 SV40 map units) and the second representing the body of the early mRNAs (0.38 SV40 map units). Poly(A)$^-$ RNA contained only the band of the nonspliced RNA while poly(A)$^+$ cytoplasmic RNA contained one band corresponding to the processed early mRNA body. This finding supports previous studies which indicated that polyadenylation of RNA precedes splicing[23,24]. The t (0.12 map units) and T (0.065 map units) leader segments have been run off this gel to obtain a better resolution of the larger bands. The results of this experiment indicate that a spliced early mRNA is synthesised during the infection of differentiated mouse embryo cells by SV40. The detection of the full early transcript in the total cell (nuclear-plus cytoplasmic) RNA as well as the poly(A)$^-$ RNA suggests that the mature cytoplasmic spliced RNAs are derived from this primary transcript. Of particular importance is the detection of the primary transcript alone in the infected F-9 cells. This finding suggests that a major block to SV40 gene expression in F-9 cells is related to the inability to splice the primary transcripts. We cannot exclude, however, the possibility that an additional step in SV40 gene expression, for example the initiation of SV40 transcription, is also depressed in these cells. Nor can we exclude the possibility that other embryonal carcinoma cell lines may have other restrictions to SV40 gene expression. In contrast, spliced early SV40 mRNAs are efficiently produced in differentiated mouse embryo cells. Recent experiments using SV40 deletion mutants[16,25,26] and recombinant DNA molecules (D. Hamer and P. Leder, personal communication) have shown that non-spliced viral transcripts do not accumulate in a stable form. As the undifferentiated cells seem to be unable to splice primary transcripts, this might explain the very low levels of virus-specific RNA in SV40-infected F-9 cultures.

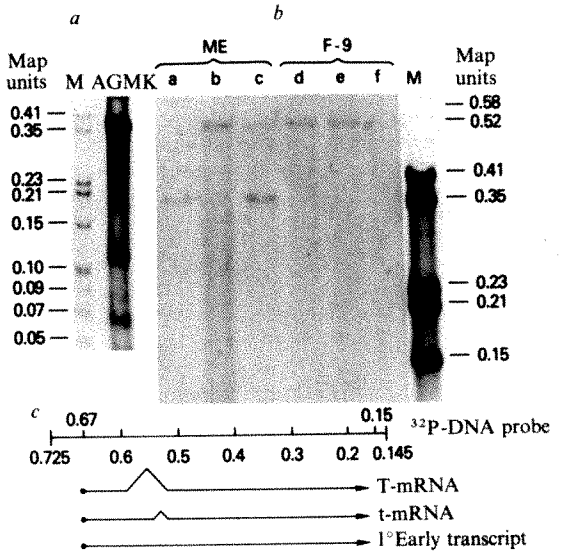

Fig. 4 Sizing of transcripts from SV40 infected mouse embryo (ME) and F-9 embryonal carcinoma cells. Total cellular RNA, poly(A)$^-$ and poly(A)$^+$ cytoplasmic RNAs were extracted from ME and F-9 cells, 10 h after infection with SV40 (250 p.f.u. per cell). These RNAs were separately annealed with a single-stranded ^{32}P-SV40 DNA probe (1.5×10^6 c.p.m. μg^{-1}) extending from map units 0.145 to 0.725 and representing the entire early region of SV40. Preparation of this probe has been described in detail[19]. After annealing for 18 h at 37°C in 50% formamide, 0.4 M NaCl, 0.04 M PIPES buffer (*p*H 6.8), hybrid molecules were digested with an excess of nuclease S_1 (45°C for 30 min) and analysed by alkaline agarose gel electrophoresis[21]. The products of S_1 analysis of hybrids between the early strand probe and poly(A)$^+$ cytoplasmic RNA from SV40-infected permissive MK cells are a control (*a*). Three prominent bands are evident representing the splicons for T- and t-mRNAs (0.065 and 0.12 map units) as well as their 3'-body segment (0.38 map units). *b*, S_1 products of hybrids between the same DNA probe and RNA from SV40-infected ME (a,b,c) or F-9 cells (d,e,f). The RNA preparations included poly(A)$^+$ cytoplasmic RNA (a,d) poly(A)$^-$ total cellular RNA (b,e) and total infected cell RNA (c,f). M, DNA size markers. Map units are given as fractional lengths of the SV40 genome. *c*, The two splices SV40 lytic mRNAs (encoding T and t peptides) and primary early transcript from which they are thought to be processed.

The resistance of F-9 cells to viral infection is not limited to SV40. In addition, polyoma virus[1,6] and ecotopic murine C-type viruses[2,3] are not expressed in undifferentiated, embryonal carcinoma cells. Note that each of these viruses induces spliced mRNAs. A number of other viruses including Sindbis, encephalomyocarditis virus, and vaccinia virus[2] can grow in the undifferentiated embryonal carcinoma cells; but these viruses have not been shown to require splicing for their mRNA maturation. In contrast, the maturation of adenovirus 2 mRNA relies on a splicing mechanism; yet this virus is expressed at low levels in the undifferentiated cells[5]. We therefore suggest that adenovirus may use a distinct processing system in F-9 cells. Such enzymes could be cellular, virus induced or virus coded. The appropriate splicing of SV40 RNA only in the differentiated mouse cells[4] raises the possibility that cell maturation itself is based on the expression of splicing enzymes. It is important to determine if only those mRNAs encoding differentiated functions require splicing, and if the enzymes required for the steps in RNA maturation such as splicing are induced in differentiating cells.

Using the method of Strickland and Mahdavi[8] we have been able to induce the F-9 teratocarcinoma cell line to differentiate. The differentiated cells, after SV40 infection, contain spliced early SV40 mRNAs and synthesise SV40 T-antigen as demonstrated by immunofluorescence and immunoprecipitation (S.S. and G.K., in preparation).

The relationship of degradative and resistance plasmids of *Pseudomonas* belonging to the same incompatibility group

THE fluorescent pseudomonads include *Pseudomonas* which can cause serious infections in man, and soil bacteria such as *P. putida*. Resistance (R) plasmids have been found in strains of both species and degradative (D) plasmids have been demonstrated in strains of the latter species. Where such plasmids can be transferred by conjugation to a common host strain, it has been possible to establish whether they can stably co-exist. Inability to co-exist (incompatibility) is the basis of their classification[1,2]. It has recently been suggested that both the IncP-2 and IncP-9 groups contain both R and D plasmids[2,3]. In addition the IncP-2-plasmids are both very large[4]. Among R plasmids of enterobacteria, incompatibility is generally an indication of evolutionary relationship in that the DNAs of incompatible plasmids show greater homology with each other than with those of compatible plasmids[5]. However, cases of incompatible plasmids lacking significant homology have also been reported[5,6]. We have examined the extent to which two R plasmids from *P. aeruginosa* and two D plasmids, one from *P. putida* and the other from *P. aeruginosa* (all assigned to the IncP-9 group[3,15,16]) share common sequences. The results suggest that plasmids of the same incompatibility group are not necessarily closely related.

The plasmids used in this study are described in Table 1. Plasmid pMG18 carries the same resistance determinants as R2, plus several additional ones. Plasmids NAH and TOL encode the degradation of naphthalene and toluene respectively. In the course of both degradations, catechol is cleaved and degraded via the *meta* (α-ketoacid) pathway. However, the R plasmids have no known function in common with the D plasmids.

Table 1 Plasmids used in this study

Plasmid	Original host strain	Host strain in this work	Phenotype	Approximate size of plasmid DNA (kilobase-pairs)†	Ref.
R2	*P. aeruginosa*	PU21	CbSmSu	73	7
pMG18	*P. putida*	PU21	CbGmKmSmSuHg	100	8
NAH	*P. putida*	PpG7	Nah	72	9, 10
TOL	*P. putida*	PaW1	Tol	117	11

Abbreviations: Cb, Gm, Km, Sm, Su, Hg: resistance respectively to carbencillin, gentamicin, kanamycin, streptomycin, sulphonamide and Hg^{2+}. Nah, Tol: ability to use naphthalene and ability to utilise toluene and *m*- and *p*-xylenes.

* R2 and pMG18 were transferred from *P. aeruginosa* strain PU21[12], which carries cryptic plasmids[13], to a plasmid-free *P. putida* strain, AC34[14].

† The plasmid sizes were estimated from the sum of the sizes of the fragments derived from *Eco*RI cleavage and resolved on agarose gels. Fragments of λ DNA run on the same gels were used as reference markers.

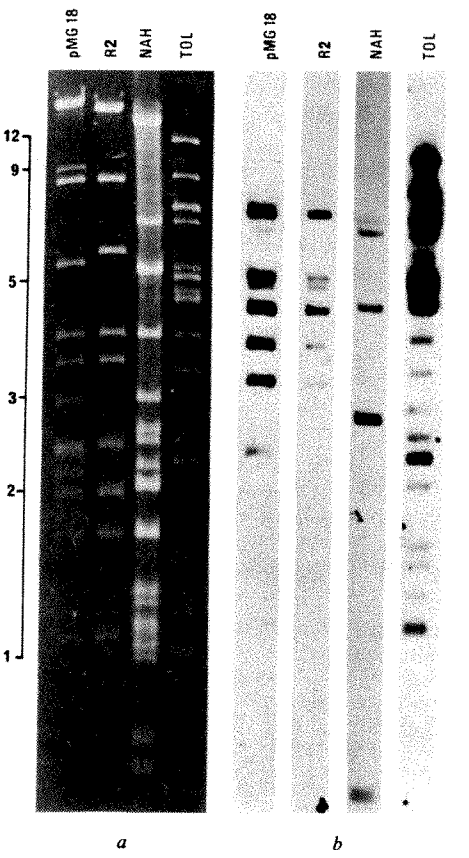

Fig. 1 *a* Banding patterns of *Eco*RI-digested plasmid DNA after electrophoresis on 1% agarose gels and staining with ethidium bromide. *b* Autoradiographs obtained by transferring *Eco*RI-digested fragments of TOL DNA to nitrocellulose filters by the Southern blot technique, and hybridising with the four different ^{32}P-labelled plasmid probes[10]. Probe DNA was labelled by 'nick translation' with [α^{32}P]-dCTP and sheared by sonication to an average length of 500 base-pairs. Hybridisation was performed in Denhardt's solution[20] at 65 °C for 18 h. Autoradiography was carried out for 24 h and then for a further 3 days to reveal weakly hybridising bands. The autoradiographs presented here were exposed for 24 h.

Overall homology was established by DNA : DNA hybridisation on nitrocellulose filters[17]. Plasmid pMG18 contained sequences that were homologous with most, if not all, of R2 (Table 2). The extent of homology in the reciprocal hybridisation (67%) was close to that expected (69%) from this experiment, given that pMG18 is larger than R2 (100 kilobases compared with 73 kilobases).

TOL DNA showed significant homology with both R plasmids (Table 2). Given that the sizes of TOL and R2 are 117 and 73 kilobases respectively, the TOL : R2 hybridisation showed that the two plasmids shared sequences of DNA equivalent to about 11 kilobases (the average of 117×0.11 and 73×0.14). Similarly, we calculated that the DNA sequences common to TOL and pMG18 are equivalent to 20 kilobases (117×0.17 and 100×0.20). However, the R plasmids shared much less homology with NAH; here, the common sequences were only equivalent to about 3 kilobases.

Previous data had suggested that NAH and TOL were related[10]. We found that the extent of this relationship was small. The degree of reassociation of TOL DNA probe with unlabelled NAH DNA was $12 \pm 2\%$, and the reciprocal hybridisation gave $8 \pm 3\%$ reassociation. Thus, we calculated the sequences common to both plasmids as being equivalent to only 9 kilobases (72×0.12 and 117×0.08).

© Macmillan Journals Ltd 1979

To localise the related segments of the R and D plasmids and to confirm that the observed homology between NAH and the R plasmids was significant, a series of hybridisations was performed, using radioactively-labelled probe DNAs of the plasmids and Southern blots of endonuclease-generated fragments of unlabelled plasmid DNAs[10].

The close similarity in size between most of the R2 fragments and a series of pMG18 fragments again suggested that R2 was very closely related to pMG18 (Fig. 1*a*). This was borne out by autoradiography, which showed that all R2 bands hybridised with pMG18 probe, and all but three bands in the pMG18 pattern showed homology with R2 probe (data not shown).

In the filter hybridisations described above, pMG18 showed more homology with TOL than did R2. As expected from this result, TOL probe hybridised with more pMG18 bands than R2 (data not shown). These findings were confirmed in reciprocal experiments with pMG18 and R2 probes, which hybridised with the same resolved bands of TOL DNA, plus, in the case of pMG18, several additional bands (Fig. 1*b*). Since these represented small fragments, they were insufficient to account for the difference between 20 and 11 kilobases. However, some of the TOL bands which showed homology with both R plasmid DNAs were composed of more than one fragment, and comparison of the autoradiographs suggested that pMG18 probe was hybridising to a greater degree to some of those bands than did R2 probe.

The results of the NAH hybridisation against TOL DNA essentially confirm those of Heinaru *et al.*[10] for the SAL plasmid, which is very closely related to NAH: that is, homology was largely confirmed to a few bands (Fig. 1*b*). Of these, band 4 in the TOL fragmentation pattern, composed of one fragment species[21], is lost from the Tol$^-$ excision derivative of TOL, pWWO-8 (ref. 22). Only one TOL band showed some homology with all the probes. However, since this band was made up of more than one fragment species, we cannot say if the same fragment hybridised in each case: indeed, the homology could also be in different portions of one fragment.

When each of the R plasmid DNAs was used to probe the NAH digestion pattern, they only hybridised (relatively weakly) with the 5.8-kilobase band. This band was also one of those which hybridised with TOL probe. These findings suggest the existence of a very small 'core sequence' common to all four plasmids. Therefore, for these four plasmids of the IncP-9 group, incompatibility cannot be taken to imply more than a very limited amount of evolutionary relationship.

Table 2 Homology among R and D plasmids of *Pseudomonas* belonging to the IncP-9 incompatibility group

Total unlabelled DNA from strain-carrying plasmid	Percentage of reassociation with labelled plasmid DNA from:			
	TOL	NAH	R2	pMG18
TOL	100±6	12±2	14±3	20±2
NAH	8±3	100±2	5±1	2±1
R2	11±3	4±1	100±3	67±2
pMG18	17±4	6±2	98±3	100±2

Plasmid DNA was isolated by SDS lysis followed by NaCl–SDS precipitation of chromosomal DNA[18] and purified by CsCl-ethidium bromide density ultracentrifugation; it was then labelled *in vitro* with [α^{32}P]dCTP by 'nick translation' (ref. 19), and sheared by sonication to an average size, as determined by agarose gel electrophoresis, of 500 base pairs. The DNA was heat-denatured and used to probe an excess of unlabelled single-stranded whole cell DNA from the same plasmid-carrying strains bound to nitrocellulose filters. The hybridisation was performed at 37 °C for 18 h in 2×SSC/50% (w/v) formamide under paraffin oil[17]. The values shown are the percentages of reassociation (±s.d.) of ^{32}P-labelled plasmid DNA with unlabelled plasmid DNA. Data are of the mean of eight separate determinations, after deduction of the values from control experiments using labelled probe and DNA from the plasmid-free host strains. These control values were about 5% of those for hybridisations with DNA from cells carrying the homologous plasmid.

We thank Clive Duggleby for discussions, Jo Rennie for photography and the MRC for support.

Electron microscopic evidence for the circular form of RNA in the cytoplasm of eukaryotic cells

LINEAR single-stranded RNA genomes extracted from several RNA viruses were found to exist in a circular conformation when examined in the electron microscope in partially denaturing conditions[1–4]. The circular conformation of viral RNA presumably arises from base pairing between RNA sequences at the two ends of the RNA molecules. The biological significance of the circular structure of single-stranded RNA is still unknown. Here we report the observation of the circular form of RNA extracted from the cytoplasm of several eukaryotic cells.

Cytoplasmic RNA was extracted from HeLa cells by the procedure of Spradling *et al.*[5]. RNA were dissolved in buffer containing 0.05–0.1 M Tris, 0.005–0.001 M EDTA, *p*H 8.5, and 40–92% formamide, and spread using the basic protein monolayer technique[6]. When examined in the electron microscope, about 1–2% of the molecules could be seen to be in circular form even in highly denaturing conditions (92% formamide, 0.05 M Tris, 0.005 M EDTA, *p*H 8.5). The electron micrographs of some of the circular molecules observed are shown in Fig. 1. RNase treatment completely eliminated these molecules, suggesting that they are RNA molecules. As control, influenza virus RNA and HeLa cell ribosomal RNA were examined. No circular RNA molecules were observed in the electron microscope in the above conditions. 23S and 16S ribosomal RNA extracted from *Escherichia coli* also do not show any circular structure[1]. Therefore, we consider it unlikely that the circular structure observed in HeLa cell cytoplasmic RNA is due to random cross-over of the two ends of the RNA molecules. Furthermore, circular forms were observed even when the molecules were highly stretched by the spreading force.

'Pan-handles' were usually observed in the circular RNA. One of these presumably represents the RNA·RNA duplex formed by the base pairing of the 3'- and 5'-ends of an RNA molecule. Sometimes, the pan-handles exist in the form of 'rabbit ears' (see Fig. 1). That these structures could still be

observed in a highly denaturing condition suggested that these structures have a high degree of sequence homology and a high G·C content. Alternatively, these circular RNAs could be covalently closed as in viroid RNA[7]. The possibility that the circular RNA molecules are due to protein linkage can be ruled out because proteinase K treatment, which we did not use routinely although it is part of the RNA extraction technique[5], did not reduce the number of circles. In circular RNA molecules containing two pan-handles the pan-handles are often at an equal distance from each other.

The length distribution of circular HeLa cell cytoplasmic RNA is shown in Fig. 2. It is interesting that the size distribution seems to be of a multiple integral of 300 nucleotides (~0.22 μm). However, 300 nucleotide-long circles were not observed, probably as they are too small to be seen in the electron microscope.

The circular forms of RNA were also observed in the poly(A)$^+$ fraction of HeLa cell cytoplasmic RNA, although the length distribution is skewed to the shorter range (Fig. 3). Circular RNA can also be seen in RNA extracted from HeLa cell nuclei. However, the amount of circular RNA observed was greatly reduced when the nuclei were washed with detergent and extracted as described by Penman[8]. These results suggest that the majority of circular RNA is probably localised in the cytoplasm and not in the nucleus. Cytoplasmic RNA isolated from CV-1 cells (a monkey kidney cell line) and Chinese hamster ovary cells, and total RNA isolated from *Physarum polycephalum*, were also found to contain similar circular RNA molecules.

The biological significance of circular RNA is unknown. In the case of viral RNA it has been suggested that the pan-handles at the ends of RNA molecules may serve as the initiation site for viral RNA replication[1,2]. The circular RNA that we observed in the cytoplasm may represent cryptic viral RNA or viral RNA in chronic infection. If such were the case, one may be able to detect RNA replication activity in the post-mitochondrial cytoplasmic fraction. On the other hand, circular RNA may represent efficient templates for translation in which the ribosome running off the mRNA template at the 3′-end immediately re-associates with mRNA at the 5′-end to start new initiation of protein synthesis. This model was suggested by Baglioni *et al.*[9] to account for the slow rate of exchange of ribosomal subunits and the stability of mRNA in mammalian cells. Such a model would predict the close association of the cap structure at the 5′-end and the poly(A) sequence at the 3′-end of mRNA molecules. Partial nuclease digestion of mRNA molecules would result in the enrichment of the cap structure in RNA fragments containing the poly(A) sequence. These possibilities require experimental verification.

Fig. 1 Electron micrographs of circular RNA molecules extracted from the cytoplasm of HeLa cells. HeLa cell cytoplasmic RNA extracted according to Spradling *et al.*[5] was precipitated with ethanol at −20 °C and resuspended in 92% formamide, 0.05 M Tris, 0.005 M EDTA, *p*H 8.5, 50 μg ml^{-1} cytochrome *c* and spread on hypophase containing 50% formamide, 5 mM Tris and 0.5 mM EDTA, *p*H 8.5. The RNA molecules were picked up on a pallodron-coated grid and processed for electron microscopy as described elsewhere[10].

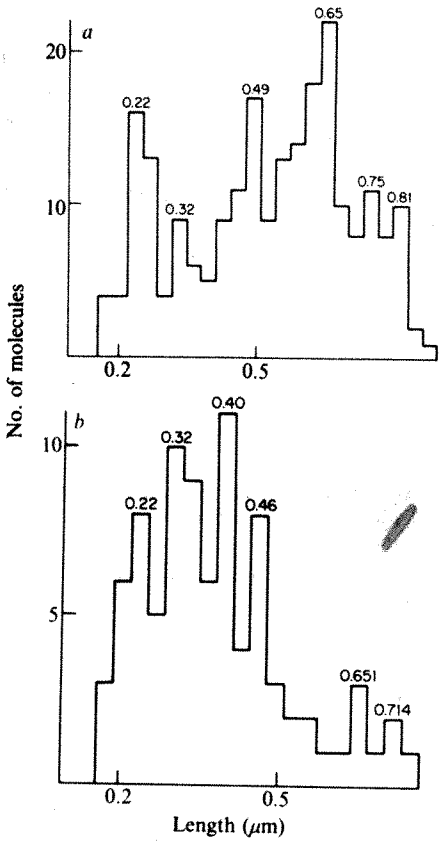

Fig. 2 Histogram of length of HeLa cell total cytoplasmic circular molecules (*a*) and cytoplasmic poly(A)$^+$ circular RNA molecules (*b*).

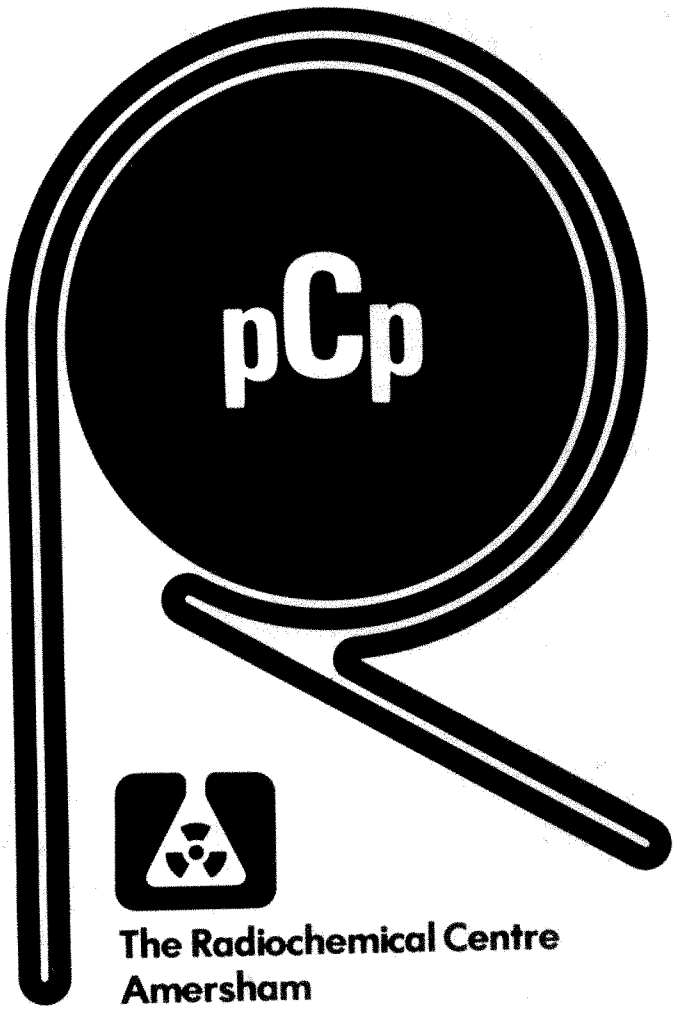

We thank E. M. Johnson for *Physarum polycephalum* RNA, R. Lamb for the influenza virus RNA and M. Saditt-Georgieff for the poly(A)$^+$ HeLa cell messenger RNA. This work was supported by grant CA 19073-03 from the NCI to M.-T.H. M.C.-P. is a fellow of the Spanish National Council of Research.

Cancer Markers
Developmental and Diagnostic Significance
edited by **Stewart Sell,** University of California, San Diego

For many years oncologists have searched for biochemical markers of cancer cells that would permit unequivocal recognition of cancerous tissue. This volume contains a rich account of the progress that has been made, and will serve not only as a reference, but also as a stimulus for the development of new biochemical and clinical approaches to cancer diagnosis and treatment. Coverage includes articles by Sell; Pierce; Panfili; Solomon; Leventhal/Civin/Reaman; Chism; Forman; Griffing/Vaitukaitis; Balinsky; Horne; Shively/Todd; Gold et al.; Gold/Goldenberg; Yogeeswaran; Nicholson; Borek; Hnilica/Briggs; Ruoslahti/Hayman/Engvall; Baldwin/Robins.

Approximately 400 pages; due late 1979; ISBN 0-89603-009-1; tentative price, $39.50

Clinical Cellular Immunology
edited by **Albert A. Luderer and Howard Weetall,** Corning Glass Works

This outstanding new volume offers thorough treatment of the principles of clinical cellular immunology, with first-rate articles by: Woodland; Luderer; Fathman; Friedman; Rose/Burek; Gottlieb/Maziarz; Sigel/Ghaffar; Fudenberg/Douglas/Schopfer; Parkhouse/Guarnotta.

Approximately 350 pages; due late 1979;
ISBN 0-89603-011-3; tentative price, $34.50

The Lymphokines
edited by **William E. Stewart II and John Hadden,**
Memorial Sloan-Kettering Cancer Center, New York

Here is a broad-scaled review of the exciting new work on the chemical factors involved in regulation of the immune response. Coverage includes articles by: Bloom; Stewart; Feldman; Block/Jasksche; Moore; Hamilton; Schimpl/Wecker; Waksman; Goetzl/Shapleigh; Hadden/Sadlik; Stanley; Old; Kirkpatrick/Burger; Rocklin/Bendtzen; Papermaster; Paetkau; Mizel; Bockman; Barom; Pierce/Katz; Hadden/Stewart.

Approximately 400 pages; due late 1979;
ISBN 0-89603-012-1; tentative price, $39.50

Medical Responsibility
Paternalism, Informed Consent, and Euthanasia
edited by **Wade L. Robison,** Kalamazoo College, and **Michael Pritchard,** Western Michigan University

Medical Responsibility contains a first-rate selection of articles on the common philosophical notions unifying the highly topical current issues of paternalism, informed consent, and euthanasia. The volume includes articles by Pritchard/Robison; Gert/Culver; Childress; Bayles; Katzner; Cohen; Shuman; Toulmin; Abrams; Browne; Mayo/Wikler; Rachels; Benjamin; Beauchamp.

July, 1979; 220 pages; ISBN 0-89603-007-5; $19.50

Contemporary Issues in Biomedical Ethics
edited by **John W. Davis, Barry Hoffmaster, and Sarah Shorten,**
University of Western Ontario, Canada
with a FOREWORD **by Daniel Callahan**

"Should medicine's goal be to forestall death, to relieve suffering, or simply to maintain health? Does the principle of the "dignity of life" or "the right to life" require that medicine always strive to keep people alive to the bitter end?" These and many other humanly urgent questions are discussed and debated in *CONTEMPORARY ISSUES IN BIOMEDICAL ETHICS.* A volume of *Contemporary Issues in Biomedicine, Ethics, and Society.*

February 1979, 336 pp.; ISBN 0-89603-002-4; $19.50

Handbook of Environmental Engineering
Volume 2: Solid Waste Management
Volume 1: Air and Noise Pollution Control
edited by **Lawrence K. Wang,** Stevens Institute of Technology, and **Norman C. Periera,** Olin Corporation

The *Handbook of Environmental Engineering* is a major new work designed to provide comprehensive treatment not only of the scientific principles underlying highly useful pollution abatement sysems, but also of their practical application in the control and improvement of environmental quality.

Vol. 1: March 1979; 512 pp., 70 illus.; ISBN 0-89693-001-6; $49.50
Vol. 2: Fall 1979, approx. 350 pp; ISBN 0-89603-008-3; tentative price. $34.50

Solar Energy
Chemical Conversion and Storage
edited by **Richard R. Hautala, R. Bruce King, and Charles Kutal,**
University of Georgia

Chemical approaches to solar energy conversion and storage are undergoing very rapid and already productive exploration. The present volume is essential reading for all those actively involved in this fascinating and crucial new discipline. A volume of *Contemporary Issues in Science and Society.*

April 1979; 440 pp.; ISBN 0-89603-006-7; $34.50

Pesticides
Contemporary Roles in Agriculture, Energy, and the Environment
edited by **T.J. Sheets,** North Carolina State University, and **David Pimentel,** Cornell University

In this significant new book distinguished scientists bring to bear a broad spectrum of interdisciplinary expertise on many of the crucial issues associated with contemporary pesticide usage, including pesticide-increased agricultural production; socio-economics of pesticides; environmental effects of pesticides; energy and pesticides; pesticide use cost/benefit ratios; human health and pesticides. A volume of *Contemporary Issues in Science and Society.*

June 1979; 208 pp.; ISBN 0-89603-005-9; $19.50

Introduction to Bioinstrumentation
with Biological, Environmental, and Medical Applications
by **Clifford D. Ferris,** University of Wyoming

"...I wish to convey my enthusiasm about the book...written from the standpoint of a beginner in the field of instrumentation theory, it presents the material logically and in an understandable way...the treatment is widely applicable and should find an eager audience not only among individuals using bioinstrumentation, but also among chemists, psychologists, physicists, and engineers."
Gary M. Hieftje, Indiana University

A volume of *Contemporary Instrumentation and Analysis,* 352 pp., approx. 120 illus.

Hardcover edition; ISBN 0-89603-000-8, $29.50
Softcover student edition: ISBN 0-89603-003-2, $14.50

Medical Information Systems
The Laboratory Module
by **Ralph R. Grams,** University of Florida College of Medicine

March, 1979; 448 pp.; 154 figures and charts.
ISBN 0-89603-004-0; $39.50

GHB NEW AND FORTHCOMING IN 1979

ADVANCES IN ENVIRONMENTAL SCIENCE AND ENGINEERING Vols 1 and 2 *Edited by James Pfafflin and Edward Ziegler*

This new serial publication is designed to bring together recent contributions from respected scholars in the field of environmental science.

Vol 1: ISBN 0 677 16070 4 296pp £27.80
Vol 2: ISBN 0 677 14810 0 224pp £27.80

RECENT ADVANCES IN ENVIRONMENTAL ANALYSIS *Edited by R. W. Frei*

This up-to-date account of the present state of environmental analysis will provide valuable information for the many researchers in the field.

ISBN 0 677 15950 1 364pp £27.50

DIGRAPHS: THEORY AND TECHNIQUES *D. F. Robinson and L. R. Foulds*

The theory of directed graphs (digraphs) and applications for analysis in real-life problems in fields from logic to O.R.

ISBN 0 677 05470 A 270pp Approx. £15.00

SYNCHRONOUS MACHINES *Mulukutla Sarma*

This book presents a unified development of the fundamental coupled-circuit theory of the transient performance of synchronous machines.

ISBN 0 677 03930 1 600pp £26.70

Announcing a New Periodical . . .

JOURNAL OF ECOLOGICAL AND LIFE CHEMISTRY *Edited by Derek Bryce-Smith and John Mann, (University of Reading)*

Brings together a wide selection of research reports focusing on distinct elements of chemical interest.

ICE AGES M

: Solving the Mystery

Professor John Imbrie and Katherine Palmer Imbrie

May 1979 £6.95 224pp 0 333 26767 2 illustrated

Knowledge that the world once endured an ice age has been widespread for more than a century. Indeed, the concept is now so familiar that nearly every winter storm prompts dramatic headlines: Is a new ice age upon us?

This book tackles that burning question and attempts to unfold, for the interested general reader and those with a more academic interest, the entire saga of the Ice Age 'mystery' – why ice ages occurred, what they were like, and when the next one is due.

It is written by one of the principal scientists on the multi-million dollar CLIMAP project which set out to study changes in the climate of the earth over the past 700,000 years. Out of the group's analytical work came an exciting by-product: confirmation of the correctness of one of the several theories of what causes ice ages to occur. The theory that was confirmed, and is now explained along with many others in ICE AGES, is the Milankovitch, or astronomical theory which sees periodical glaciation as the result of three regular movements the earth makes as it travels around the sun: changing ellipticity of the earth's orbit, "wobble" of the earth's axis, and the changing tilt of the earth's axis.

"ICE AGES is fascinating in its scientific interest and also as a detective story. I recommend it to all." Dr. William F. Libby, Nobel Laureate.

reviews

Worthwhile science

J. R. Ravetz

Science and Its Critics. By John Passmore. Pp. 102. (Duckworth: London, 1978.) Paperback £2.95.

AN advocate of an unpopular cause could not wish for an interpreter more judicious and sympathetic than John Passmore. Continuing his series of surveys of the deeper problems of our scientific world-view, in *Science and Its Critics* he handles some very controversial matters with unfailing erudition and tact.

Through four themes, he reviews the great variety of criticisms that have been made of science. The easiest to handle is the first, the claim that scientific explanation is defective as a means of real knowing. The many ambiguities in the concept of "explanation" are sufficient for the fragmentation of any line of criticism. The criticism of the destructive potential of science-based technology merits more consideration. Passmore refuses to allow the shelter of ignorance of consequences claimed by "pure" scientists. For our science is too bound up with technology, both in its present practice and in its basic philosophy as announced by Bacon and Descartes. Although the problem of personal responsibility of the scientist is not easily resolved either way, the collective involvement of science in its applications cannot legitimately be denied.

When he comes to "the scientific spirit", Passmore seems at last to be speaking more from knowledge of man than of books. He coins the useful term "aristoscience" relating to the elite practitioners of the elite fields. For that, the "spirit" requiring analysis is *hubris*. He described very compellingly how this affects the style of scientific work, right down to the self-serving criteria of choice of problems, the setting of inappropriate standards for "immature" sciences, and indeed an indifference to the welfare of ordinary people provided that scientists are well fed.

Finally, he talks of "uniqueness, imagination and objectivity", still rebutting metaphysical attacks but admitting the strength of social criticisms. And this seems to be the verdict, as it emerges towards the end. As a social institution composed of people, science is not immune from any weakness or failing. But as an ideal for knowledge, placing man in a particular relationship to the Universe, science, as the successor to the philosophies of the Renaissance and the Enlightenment, expresses the essential values of our civilisation.

Thus, in a bare hundred pages Passmore has introduced the whole field of criticism of science, including quotes from all the significant authors. Its only defect as an introductory text for students is that the argument flows rather too smoothly from one topic to the next; another edition with sections and break-headlines would much enhance its pedagogical value.

This book was written in response to the crisis of the 1960s; John Passmore might now begin working on the sequel which will be necessary for the 1980s. This epoch has just begun, inaugurated by the nuclear accident at the Harrisburg plant, Three Mile Island, Pennsylvania. In America the Press carried reflective stories with such headlines as "The Nuclear Experts Can't Be Trusted" and "Credibility Crap": "One of the first casualties of the Three Mile Island nuclear accident was scientific credibility . . ." (*Newsweek*, 23 April, 1979). How "scientists" could be involved in the same processes of prevarication, lies and cover-up as the Vietnam or Watergate politicians, is a problem which, I believe, must be considered urgently by those who would understand and defend what is worthwhile in science in the coming period. □

J. R. Ravetz is Reader in the History and Philosophy of Science at the University of Leeds, UK.

Hückel theory

Hückel Theory for Organic Chemists. By C. A. Coulson, B. O'Leary and R. B. Mallion. Pp. 182. (Academic: London, New York and San Francisco, 1978.) £9.50; $19.65. *Hückel Molecular Orbital Theory.* By K. Yates. Pp. 371. (Academic: New York, San Francisco and London, 1978.) £20.80; $32.

ORGANIC chemists are beginning to appreciate that an elementary knowledge of molecular orbital theory in its simplest form — Hückel theory — helps greatly in understanding the properties and reactions of organic molecules. These books are not the first to attempt the exposition of Hückel theory for the organic chemist, and they will not be the last; but it is possible that one of them will turn out to be the best and the other the worst.

Charles Coulson was loved by all who knew him, and deeply respected both as a scientist and as a teacher. Hückel's name is given to the theory, but it was Coulson who, first with Rushbrooke and later with Longuet-Higgins, developed it and showed how powerful it could be, for all its simplicity. He lectured on it to organic chemists in Oxford, and in 1971 the lectures were recorded on magnetic tape. Mallion and O'Leary have now transcribed the recorded lectures into print, and although they have been unable to resist the temptation to add some pretty mathematical results of their own, they have confined themselves to appendices and footnotes. The rest is Coulson: precise but not pedantic, simply expressed but not condescending and always honest and good-humoured. One can quibble about a few matters (is the ω technique of any interest now? Is free valence of any use to anybody?) but this is as thorough and readable an account of the principles of Hückel theory as we are likely to see. There are a few misprints, and a few other irritations, such as the use of "less-approximate" to mean "more accurate" and the pervasive hyphenation of adjectival phrases, as in "reasonable (but-not-exactly-correct) supposition", but these are unimportant. The prospective purchaser may be further encouraged by the knowledge that the royalties will go to the Coulson Memorial Fund at Oxford, to support foreign students of theoretical chemistry.

It must be said, however, that this excellent book has limitations in its coverage, and these limitations will be of particular concern to the very people who are expected to read it. The applications of Hückel theory in predicting reactivity are described only briefly, and the more modern ideas which have flourished in the wake of the 'Woodward–Hoffman rules' are not mentioned at all. The book provides an excellent introduction to the basic molecular orbital theory, but it does not completely serve the needs of the modern organic chemist. It is therefore not surprising that the same publisher is responsible for the book by Yates, which seeks to cover much more thoroughly these important new ideas. It is unfortunate, perhaps, that the books arrived for review almost simultaneously, for the virtues of the one emphasise the deficiencies of the other. An example of the difference is given

by the treatment of the Born–Oppenheimer approximation, which is implicit in the Hückel method but need not be made explicit in an elementary treatment. Coulson accordingly does not mention it at all. Yates mentions it twice — once to say that it muust be used, and once to say that it has been used. He does not say what it is. Another example is the treatment of the Coulson–Rushbrooke pairing theorem, which is fundamental to many of the applications of Hückel theory, and important in understanding the unexpectedly wide validity of the theory. Coulson naturally proves the theorem, carefully and precisely, so that there is no doubt about the exact assumptions which are required. Yates has no reference by name to the theorem, either in the index or, as far as I can discover, in the text; and although he could have stated the essence of the theorem, as Coulson does, in a dozen lines, he spreads the statement over several pages, calls it a series of generaliations rather than a theorem, and moreover, by introducing a further weaker generalisation, for which he gives an invalidating counter-example, leaves the reader with the impression that all of these 'generalisations' share the same lack of generality.

Yates claims, with some justice, that organic chemistry students frequently apply important ideas and approaches such as the Woodward–Hoffman rules "without a sufficiently sound understanding of their theoretical basis". Yet he fobs his readers off with phrases like "it can be shown that . . . " or "it turns out that . . . ", even where the result could be derived quite readily. Other arguments are presented in a thoroughly superficial manner. For example, the important class of sigmatropic reactions is dealt with on the basis that "the important molecular orbital of the π framework involved in the migration is considered by Woodward and Hoffman to be the [highest occupied one]". Is the student to take this *ex cathedra* statement as the basis of his sound understanding? There is no discussion of the reasons for the validity of this assumption; nor is there any cross-reference, or index reference, to a later chapter where this class of reaction is studied by another method.

Indeed, there is an irritating lack of cross-references throughout: the reader is continually being told that a certain topic will be treated "later", with no cross-reference to lead him to the right place. The index too, is thoroughly unhelpful: for example, of the four entries under "Woodward–Hoffman rules" one leads the reader to the statement that they will be treated "in the following chapters", and another to the statement that they will be described "later". None of them directs the reader to the full derivation of the rules or even to a statement of what they are.

This lack of consideration for the reader is illustrated in a different way by a sentence in the first chapter, which reads: "For the second molecular orbital . . . a similar treatment would give $E_2 = (\alpha-\beta) / (1-S)$, and since β is generally greater in absolute magnitude then α (and both are negative energy terms) this corresponds to a positive energy level or an antibonding molecular orbital". Now the author has slipped up in his statement (repeated in a diagram) that antibonding orbitals have positive energy. They merely need to have energy greater than α. If the energy had to be positive, and α and β were both negative, then it would certainly be necessary that $|\beta| \gg |\alpha|$. But this is not the case; for with the normal choice of energy scale (adopted implicitly if obscurely on the previous page) α is typically around -15 eV and β around -3 eV. Any attempt to check the relative values of $|\beta|$ and $|\alpha|$ would have revealed this fact, and, eventually, the error about antibonding energies; but the author seems to have been content to state what "must" be true. He has advertised his uncertainty by adding the word "generally", but evidently without contemplating the consequences of $|\beta|$ being less than $|\alpha|$. He also seems to be unaware that it is meaningless in any case to compare values of α and β without specifying the energy datum precisely, as they change in different ways when the datum is changed, and indeed either can be made to vanish by a suitable choice.

Let us then turn back to Coulson, O'Leary and Mallion. They will not take the reader through the important modern ideas in theoretical organic chemistry, but they will provide him with a secure foundation on which to base his study of the more specialised monographs in the field.

A. J. Stone

A. J. Stone is an Assistant Director of Research in Theoretical Chemistry at the University of Cambridge, UK.

Nature-nurture

Intelligence: Heredity and Environment. By P. E. Vernon. Pp. 390. (Freeman: San Francisco and Reading, 1979.) Hardback £10; paperback £5.30.

VERNON sets out to reconcile the conflicting claims regarding intelligence and its transmission and to adopt an eclectic position that gives due weight to all the relevant facts. To this end he presents a critical appraisal of a very large number of studies with admirable lucidity.

Although such eclecticism may sound impersonal, there certainly is no lack of personal involvement on Vernon's part, and it is this as much as anything which gives the book its fascination. In many ways it is an intensely personal statement, from the preface in which he speaks of this book as his last, to the finale in which he mounts an emotive attack on recent trends in childrearing and education and contemplates the breakdown of Western mores and standards.

As the author looks back on the half century during which he himself has made such a distinguished contribution to psychometrics, he clearly perceives that all is not well. To take a specific example, intelligence testing is being banned in some parts of the United States on grounds of cultural bias. Vernon devotes a chapter to effectively countering this accusation. But more generally, psychometrists seem to be an increasingly isolated group, disowned on the one hand by many geneticists and on the other by many developmental psychologists. From the beginning quantification has been the primary goal in psychometrics, and has arguably hindered rather than helped conceptualisation. Vernon argues that "psychometry is quite entitled to use its own brand of operationalism, regardless of philosophical theories of scientific method, provided it works". But does it work?

The bulk of the book is devoted, as the title suggests, to the nature-nurture issue. Vernon makes a plea for scientific objectivity, suggesting that questions of social and political reform are not the business of the psychologist; it is his business simply to supply scientific data. In the context of his argument it is particularly unfortunate that Vernon has been forced to acknowledge (in a prefatory notice) the evidence of systematic fraud having been perpetrated by Burt. Vernon's citations of Burt are exceeded only by those of Jensen, and even given the author's attempts to minimise his dependence on Burt's studies the affair hardly encourages us to accept the impartiality of scientific data.

The book gives detailed coverage of the heritability studies and the criticisms which have been raised against them. Although Vernon offers a stalwart defense of the attempt to estimate heritability, the sheer variety of methodological and statistical doubts raised by critics of the various studies may tend further to undermine the reader's confidence.

Vernon's equivocates on racial differences in intelligence, suggesting that it is highly probable that some genetic differences are involved, but that owing to the confounding of race with environmental differences it does not seem possible to separate their effects. To paraphrase the ancient Zen argument, it may be that the real problem lies not so much in our question being unanswerable, as in our remaining in the state of mind that led us to ask it.

Paul Light

Paul Light is Lecturer in Developmental Psychology at the University of Southampton, UK.

ANNOUNCING

Oncodevelopmental Biology and Medicine

The Journal of the International Society for Oncodevelopmental Biology and Medicine

Aims and Scope

Oncodevelopmental Biology and Medicine is devoted to the rapid publication of studies concerning all aspects of oncodevelopmental sciences in a broad sense: the recognition of phenomena and the characterization of markers of ontogeny and differentiation in order to provide a basis for the advancement of methods for the diagnosis and management of cancer and other disorders related to ontogeny. The journal is focused on gene regulation, synthesis, chemistry, biology and clinical application of oncodevelopmental gene products like carcino-embryonic proteins, isoenzymes, hormones, and provides a forum for a multidisciplinary approach to cancer as a problem of development.

Type of Papers

1) Full-length papers (generally not exceeding 10 printed pages)
2) Short communications not exceeding 2000 words or equivalent space including figures, tables and references (for example 1500 words including references and 2 figures or tables). These must be brief definitive reports and not preliminary findings.Short communications will be published like full-length papers (not described as 'short papers') but more rapidly,
3) Reviews will be published following an invitation from the editors-in-chief.

Advances in metabolism

The Year in Metabolism, 1977. Edited by N. Freinkel. Pp. 448. (Plenum Medical: New York and London, 1978.)

THIS volume is the second in what is proposed to be an annual series, the purpose of which is to review advances in metabolism. The publishers have assembled an impressive list of internationally recognised experts to produce twelve chapters on diverse topics. The appeal of a series like this depends not only on the appropriate choice of subjects;in order to attract the non-specialist, recent advances have to be made intelligible to those without extensive background knowledge. In both respects this volume is largely successful. If there is any unevenness of presentation it is because some of the authors have interpreted their brief literally and dealt only with recent advances, whereas others have written general reviews with extensive references to the earlier literature.

The review by Murad and Aurbach on cyclic GMP metabolism, particularly in relation to disease states, is timely and draws together data which is not readily to be found elsewhere. The chapter by Fajans on diabetes mellitus provides a useful account of genetic aspects and the linking of susceptibility with the HLA system and a possible viral aetiology. Insulin resistance is also discussed together with various aspects of treatment, and there is a good account of possible pathogenic mechanisms in the development of vascular complications.

Another chapter contains an authoritative account of glucagon and somatostatin by Unger. Topics discussed include structure-activity relationships, control of secretion and the bi-hormonal (glucagon and insulin) hypothesis of diabetes mellitus. Inevitably there is some overlap with the chapter by Feligand Koivisto on body fuel metabolism, in which the inter-relationships of glucagon, insulin and somatostatin are considered. Hirsch writes about obesity, discusses what is new and concludes not much. His philosophical discussion of causation and treatment ends on a pessimistic note for the sufferer. Lipids and lipoproteins are discussed by Goodman who selects highlights from a complex subject with care.

Rosenberg's chapter on amino acid discorders also selects a few topics for discussion, including phenylketonuria, the glutamyul cycle and oxoprolinuria. He also gives a fascinating account of the metabolic mechanisms underlying Jamaican vomiting sickness, which is due to the presence of the unusual amino acid, hypoglycin, in unripe ackee fruit.

Seegmiller offers an extensive and detailed account of how human disorders of purine and pyrimidine metabolism are linked to an immunodeficiency syndrome. Possible mechanisms are discussed.

The topic of divalent ion metabolism is covered expertly by Coburn, Hartenbower and Kleeman, who draw attention to how recent advances in vitamin D metabolism are enabling some of the clinical disorders to be better understood. The complex inter-relationships between PTH, vitamin D and calcium, phosphate and magnesium metabolism are summarised. Winick deals with the topic of nutrition, growth and development with particular emphasis on malnutrition, genetic obesity and nutrition in pregnancy. Finally, Williams provides a short but useful review of renal stone disease, and Lieber reviews the metabolism and metabolic actions of ethanol.

The same group of authors have been recruited to contribute to future volumes and this may introduce some difficulties in producing a wide enough variation in subject matter in future editions. It will be interesting to see whether the publishers and authors can maintain the same high standard to be found in this volume.

The book should appeal to a wide audience which should include biochemists concerned with human disease and teaching medical students, as well as endocrinologists and physicians with interests in metabolic disorders.

R.G.G. Russell

R.G.G. Russell is Professor of Human Metabolism and Clinical Biochemistry at the University of Sheffield Medical School, Sheffield, UK.

Disorder in crystals

Disorder in Crystals. By N. G. Parsonage and L. A. K. Staveley. Pp. 926. (Oxford University Press/Clarendon: Oxford, 1979.) £28.

IN the hierarchy of matter — gas, liquid, crystal — crystals signify order, pattern; they represent classical discipline as against romantic anarchy. "Damn braces, bless relaxes!" cried that arch-romantic, Blake. The authors of this impressive text might have taken Blake as their mentor; their crystals are for ever relaxing from a state of Roman order into one of Italian disarray; same place, changed ways.

The book is about the various ways in which crystals can lose perfect regularity without ceasing to be crystals: it is a study of local variability superimposed on a basic periodicity. The authors in their Introduction (which neatly summarises the argument of the book) distinguish three types of disorder: disorder of position, orientational disorder and magnetic disorder. These might respectively be exemplified by Cu_3Au, where copper and gold atoms are apt to trespass on each other's appointed lattice sites; NH_4Cl, in which a triad axis of the $(NH_4)^+$ ion can point in different defined directions and the ion itself can execute a click-stop rotation about a triad; and $CsCoCl_3.2H_2O$, containing one-dimensionally ordered antiferromagnetically coupled chains of tilted 'Ising spins'. Any chemist, physicist or metallurgist, however expert he may be in one or other of these very broad categories of disorder, will discover a great variety of parallels to and variants of the particular kind of behaviour he is familiar with. The book is a remarkable achievement of synthesis.

The text begins with a detailed treatment of the thermodynamic and statistical mechanical approaches to phase transformations and degrees of order: it is a mark of the combined rigour and flexibility of the authors that they do not agonise about the propriety of classifying order/disorder transformations as phase transformations. The Ising lattice theory in various dimensions receives a full historical survey, as do the various thermodynamic approaches to the order of transformation; the concept of the λ transformation is frequently cited throughout the book. Even such a technical subtlety as the bond percolation problem (if water be imagined capable of percolating along one type of bond only in a crystal, what proporton of the atoms would be wetted if the crystal were bathed in water?) gets due attention.

There is next a useful chapter on experimental techniques, such as thermochemical measurements, diffraction, NMR, IR and Raman spectroscopy, dielectric permittivity, dispersion and loss measurements, and others. The aim is to explain what kinds of information the various methods can provide, and why; no attempts are made to describe hardware or practical difficulties.

The authors then settle down to particular materials, starting with positional order in alloys. As a metallurgist, the reviewer can confirm that this chapter is reasonably up to date and quite clear in classifying and exemplifying the types of positional order. No attention is devoted here, and little elsewhere in the book, to the kinetics of order–disorder transformations, which is a major topic of current metallurgical concern; and microstructure — for instance, the curious structures resulting from spinodal decomposition — is not considered. Again, some important concepts are not explained but simply used: the notion of 'antiphase domain' is an example. This omission of

definitions happens at intervals in both the theoretical and experimental parts of the book but, given its ambitious scope, this could hardly have been avoided.

The next five chapters (432 pages) constitute the heart of the book. The first, dealing with positional disorder in inorganic compounds, covers in particular the currently important topic of superionic conductors such as an allotrope of AgI, and beta-alumina. (The authors say of AgI that "this singular crystal has often been described as consisting of fluid silver ions in a solid lattice of iodide ions, and even as a 'missing link' between the solid and liquid states".)

A long and illuminating chapter follows on orientational disorder in salts, pride of place going to ammonium salts and including a treatment of ferroelectric salts. This is followed by a clear disssection of the exceedingly involved polymorphs of ice, most of them created by high pressure, and the various descendants of Pauling's statistical mechanics of hydrogen bonds in ice are described.

Two chapters follow on molecular solids, with special emphasis on compounds (such as perfluorocyclohexane) which contain both fixed and labile constituents. Such compounds, called 'rotator phases' or 'plastic crystals', in which some ions exhibit extreme orientational disorder, have remarkable properties such as extreme softness and very rapid diffusion, at appropriate temperatures. Hydrogen and deuterium, various linear and non-linear molecules, and many other groups are analysed, and the chapter finishes with a valiant attempt to systematise the statics and dynamics of these variegated molecular groupings. The concept of a glassy crystal (in which disorder of ions on a sublattice is frozen in on cooling) is introduced. Long-chain monomer molecules are treated quite fully, but degrees of order in polymers are not discussed at all. A special feature in these chapters is the close attention paid throughout to the implications of thermal analysis and, in particular, of the entropy changes associated with order transformations.

A further chapter discusses clathrates (compounds such as β-quinol with large near-spherical structural voids that can be partially filled with 'guest compounds', which behave as independent non-interacting parasites on the host), channel compounds of urea and thiourea, and the metallic intercalates of graphite studied in recent years. An example of what can be deduced from entropy measurements is the authors' conjecture that cyclooctane molecules caught in thiourea channels undergo conformational changes, limited by the channel geometry, at sharply defined temperatures. It would be intriguing to know how polymer chains would behave if constrained within such a host.

The final chapter deals with inorganic magnetic compounds, first in quantum-mechanical generality and then in taxonomic and specific detail. The reader is taken through the luxuriance of phenomena such as ferromagnetism, antiferromagnetism, spin waves, metamagnetism, helical spins, and their hybrids.

After this plethora, it is only proper to outline what the authors have omitted. As already mentioned, polymers are excluded. There is no reference to liquid crystals, that other missing link, which is a pity since, in terms of statistical mechanics, they show a temperature dependence closely similar to that of the Bragg–Williams theory of positional order in alloys or the standard theory of corresponding ferromagnetic states. These omissions are not explicitly justified; other omissions, such as a treatment of the structural implications of non-stoichiometry, or ordering of point, line or planar defects, are made explicit in the Introduction, on the grounds that they have been well covered elswhere.

One can quibble at the margins about omissions and undefined concepts, but the final impression left is of a *tour de force*, a synthesis which has no competitor. The book deserves the close attention of adventurous inorganic and solid-state chemists, solid-state physicists (especially theoreticians) and physical metallurgists. The printing is by facsimile reproduction of typescript, but is quite clear, and in view of its size and scope the book is not overpriced.

R. W. Cahn

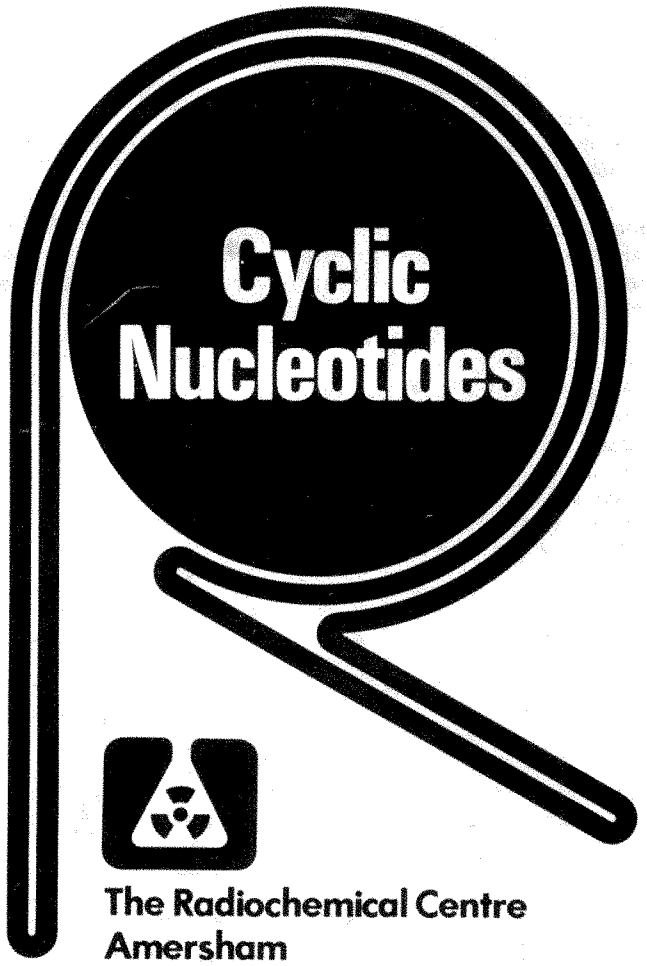
R. W. Cahn is Professor of Materials Science at the University of Sussex, Brighton, UK.

Pollination ecology revived

The Principles of Pollination Ecology. Third edition. By K. Faegri and L. van der Pijl. Pp. 244. (Pergamon: Oxford, 1979.) Hardback £12.50; paperback £7.50.

POLLINATION ECOLOGY is certainly not a new subject, having developed essentially during the eighteenth century and having been given new impetus by the work of Darwin in the nineteenth century. But it is a subject in which interest has lapsed somewhat until relatively recently, perhaps because its study has demanded patient and precise observation rather than more fasionable sophisticated experimentation. It may well be that this very fact is leading to a resurgence of interest in the subject, particularly on the part of the very considerable army of amateur bontanists in Britain. Already the energies of this eager body have been channelled into the detailed mapping of the British flora and now, under the auspices of the Botanical Society of the British Isles, information is being sought regarding the insect visitors to flowers.

In this academic climate, it is apt that Faegri and van der Pijl should launch a third edition of their classic survey of pollination ecology. The last edition was published in 1971 and since that time a great deal of new work has appeared in the literature. In their current bibliography about 30% of references date from this period, and this will indicate the extent of textual revision.



The book has retained its original arrangements, with chapters on general principles of abiotic and biotic pollination, attractants, pollination and speciation, and so on; and then a series of detialed and illustrated case studies of particular plant species. The latter are particularly informative, although the drawings are sometimes so heavily stippled that structural clarity is lost. Simple line drawings would have been preferable.

In general, the text is turgid, probably because it is so heavily packed with examples and references. Although the bibliography is extensive and valuable, perhaps the book could have been improved from the point of view of undergraduate teaching if fewer examples had been dealt with in greater detail. The text generally lacks the diagrams that could have made many points more easy to graps. Frequently an unreasonable familiarity with the literature is assumed and one is referred to the "well-known case of . . ." without further explanation. The full benefit of the text can certainly be obtained only with the backing of a good reference library.

In comparison with Proctor and Yeo's *Pollination of Flowers* (Collins: London, 1973) which, rather surprisingly, is not referred to in the bibliography, this book excels in its crystallisation of fundamental principles from a plethora of facts and observations, but falls short in its coverage of insect adaptations and in the quality of its illustrations. It is, however, a book which should stimulate further interest and research in an area of biology where plants and animals tend to interact to mutual benefit. For this reason alone it is a sadly neglected aspect of ecology which could prove a fruitful subject for practical teaching in undergraduate ecology courses. This book may lead to such developments.

CENTRALLY ACTING PEPTIDES
Edited by J. Hughes

A Biological Council Symposium on Drug Action

The 1977 symposium, on which this book is based, was stimulated by the dramatic increase in research into functionally active peptides in the central nervous system. These peptides are a major group of neurotransmitter agents, and their discovery has given added impetus to brain research. Electrophysiological, biochemical and behavioural techniques have all helped to further our knowledge, with radio-immunoassay and radiofluorescence contributing to major advances in the field.
The papers here deal with all these approaches, and also point out the many gaps remaining in our understanding of peptides. The book thus gives a timely review of the current state of research, and will be invaluable to anyone already involved in the area.

Fair's Fair.

The Institution of Professional Civil Servants is in dispute with the Civil Service Department over pay – or, rather, over the principles upon which rates of pay are agreed.

The Institution's members in the Professional and Technology grades are being invited to accept a change in criteria which will lead to an effective cut in their relative salaries and a real reduction in their standard of living. This is unfair.

The following information is intended to explain why the Institution, its National Executive Committee, and its members feel it right to resist this unfairness by every legitimate means.

Who is affected?

About 65,000 civil servants whose training, experience and qualifications in work of great value to the nation have, for a number of years, been rewarded on the basis of pay principles of considerable simplicity (as we shall explain below).

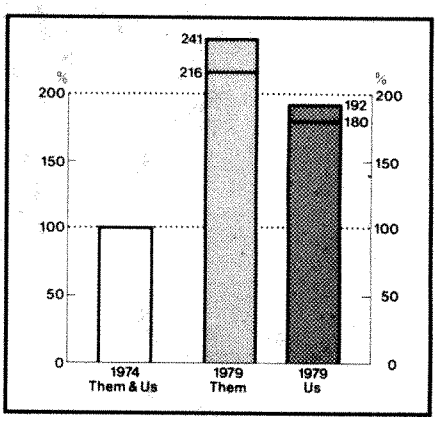
They are, for example, architects, chemists, engineers, surveyors, and technologists of every kind. They work at Royal Ordnance Factories, in the Royal Dockyards, at the Clyde Polaris Submarine Base, at Atomic Energy Research Establishments, at Scotland Yard, at Heathrow, at the Royal Aircraft Establishment at Farnborough, at Aldermaston, in the Health and Safety Executive, in the Royal Mint and hundreds of other places where work vital to the nation is carried out. Useful people, you might think. Worth paying properly, too.

What were the principles up to now?

Very simple in essence. Comparison with similar jobs in private industry is the agreed method of settling the pay of most civil servants. So our members' work was compared with that of similar staff in seventy-five organisations outside the Civil Service. From these outside pay rates an agreed "median" salary (i.e. the middle one of the whole range of salaries) can be obtained.

This is conventionally used in most Civil Service pay settlements. However, because of the special nature of our members work it has always been accepted that they deserved "pay somewhat above the average" (to quote the Report of the Royal Commission on the Civil Service). This has been agreed time after time by the Civil Service Department and confirmed by the Civil Service Arbitration Tribunal as is shown in the following table:

1965 pay agreement	**medians + 11%**
1969 pay agreement	**medians + 13%**
1972 pay agreement	**medians + 15%**
1974 arbitration award	**medians + 20%**
1975 pay agreement	**medians + 13%**
Contrast that history with the situation in 1979:	
Civil Service Dept offer:	**medians + NOTHING!**



You will immediately conclude that, obviously, there must be a reason. But the Institution of Professional Civil Servants cannot imagine what it can be; nothing has changed since previous settlements. And the Civil Service Department won't tell us. Perhaps they can't imagine what it could be either!

What do the figures really mean?

The easiest way to show why our members are so upset is to compare the 1979 offer with the salaries of those who are used as comparisons outside the Civil Service.

The 1974 salaries of those outside the Civil Service and those inside are represented by the 100% bar in the left hand column of the chart. That is the year of the Civil Service Arbitration Award. In 1979, those outside the Civil Service are being paid between 216% and 241% of their 1974 salaries. That is represented by the lightly dotted bar. (During the same period earnings generally as measured by the official index have moved by 240%.) Those inside – our members in Professional and Technology grades – are being offered between 180% and 192% of the true value of the 1974 award. That is the darker bar in the right hand column.

You see why we describe this as "effectively a cut in salary" and a positive cut in living standards.

Why not arbitrate?

A natural question – especially in view of the fairness of the 1974 award. But arbitration is only right when the processes of negotiation are exhausted. The Civil Service Department will not even start negotiations on the issues in dispute.

What should be done?

There is a simple way to bring the dispute to an end. The Institution is very ready to accept that an independent conciliator should bring the two parties together and assist them towards a solution. Isn't that a responsible attitude and shouldn't the Government respond?

You may now see why our members feel that they have been attacked by their employers and therefore have to defend themselves against what by any standards is unfair treatment. But the Civil Service Department is not really our employer – the Government is! And it represents the whole nation. It represents you.

DoYOU want a fair settlement?

Awards

Robert Koch Prize in the Medical Sciences has been awarded to **Prof. Ruth Arnon** of the Weizmann Institute's Chemical Immunology Department and to **Prof. Peter Starlinger,** Director of the Institute of Genetics at the University of Cologne.

The Charles Hatchett Award and Medal of The Metals Society has been jointly awarded to **Dr Gilbert R. Speich** and **Donald S. Dabkowski,** both of U S Steel Corporation Research Laboratory.

The Chemical Society Awards for 1978 have been presented to: **Professor G.C. Bond** (Brunel University), **I. Jones** (Sir Hugh Owen School); **Professor C.F. Cullis** (The City University, London); **E.A.V. Brewester** (Davy International, London); **Dr K.U. Ingold** (National Research Council, Canada); **Professor E.A.V. Ebsworth** (University of Edinburgh); **Professor A.R. Battersby** (University of Cambridge); **Professor M.F. Lappert** (University of Sussex); **Professor D.A. King** (University of Liverpool); **Dr. R. Freeman** (University of Oxford).

Dr Trevor Cole CSIRO Division of Radiophysics has been jointly (with **Dr M.G. Clark** of the Clinical Biochemistry Unit, Flinders University Medical School) awarded the Edgeworth David Medal of the Royal Society of New South Wales.

Candidacy to The Harkness Fellowships is open to men and women in any profession or field or study, who are citizens of the UK and have received both secondary schooling and further eduction (or equivalent professional experience in lieu of further education) wholly or mainly in the UK. Candidacy is not open to persons who, between their 19th birthday and 1st September 1980, will have spent more than six consecutive months in the U S. Candidates must be between 21 and 30 yr of age on 1st September 1980, unless qualified in medicine or employed in the Civil Service or the media, in which cases the upper age limit is 33. By that date they must have a degree; *or* an equivalent qualification conferred by a professional body; *or* an outstanding record of achievement in the creative arts, journalism or other comparable career. Within the given age range, preference will be given to younger applicants. Applications: send a s.a.e. carrying 16p postage, and measuring not less than 10 inches by 7 inches, to The Harkness Fellowships (U K), Harkness House, 38 Upper Brook Street, London W1, UK.

The John Eggert-Prize-Foundation will be offered for the fourth time in 1980. Young scientists are encouraged to submit papers from the field of Imaging Science. Imaging Science is meant to embrace a wide field, comprising Optics, Photography with and without silver halides, digital and electronic methods of Image Recording, Analysis and Processing as well as the Physiology and Psychology of Vision. Applications with complete literature references in duplicate should reach Prof. Dr W.F.Berg, at the Dept of Photography, Swiss Federal Institute of Technology, CH-8092 Zürich, no later than 15 October 1979.

Meetings

4-11 August, **STSA/SISCON 1979 Summer Conference,** Coleg Harlech (Chris Prior, Dept of Complematary Studies, The Polytechnic, Huddersfield, UK).

20-25 August, **3rd International Conference on Surface and Colloid Science,** Stockholm (Conseil de l'Europe, F-67006 Strasbourg Cedex, France).

25 August - 9 September, **25th World Vegetarian Congress,** Loughborough (Philip Brown, 53 Marloes Rd, London W8, UK).

12-14 September, **Symposium on the Gunong Mulu National Park Sarawak,** London (A.C. Jermy, c/o Mulu Office, Royal Geographical Society, 1 Kensington Gore, London SW7, UK).

27-28 September, **Vegetables for Feeding People and Livestock,** London (Institute of Biology, 41 Queen's Gate, London SW7, UK).

8-10 October, **6th Biennial Symposium on Turbulence,** Missouri (G.K. Patterson, Chemical Engineering Dept, University of Missouri-Rolla, Missouri 65401).

9-10 October, **Instrumentation in Potentially Explosive Atmospheres,** London (Mrs R.G. Keiller, Sira Institute Ltd, South Hill, Chislehurst, Kent, UK).

11 October, **Personal Protection against Air and Surface Contamination,** London (Professor J.H. Martin, Dept of Medical Biophysics, Blackness Laboratory, University of Dundee, UK).

12-15 October, **5th EMBO Annual Symposium Nucleic Acid - Protein Interactions,** Heidelberg (Dr J. Tooze, EMBO, Postfach 1022.4, 69 Heidelberg 1, FRG).

16-18 October, **30th Annual Fall Meeting of the American Physiological Society,** New Orleans (Steven K. Herlitz, Inc. 850 Third Ave, New York, New York 10022).

18 October, **Process Development Technology Symposium,** London (The Institution of Chemical Engineers, Geo. E. Davis Building. 165-171 Railway Terrace, Rugby, UK).

22-25 October, **RECLAN 79,** Eastbourne (The Conference Secretariat, Society of Chemical Industry, 14 Belgrave Square, London SW1, UK).

18-20 December, **Receptors at Cell Surfaces,** London (Dr D.A. Rees, Unilever Research, Colworth Laboratory, Sharnbrook, Bedford, UK).

13-15 January 1980, **6th Annual Meeting of the International Embryo Transfer Society,** Denver 9 Mrs S. Seidel, IETS, 3101 Arrowhead Rd, LaPorte, Colorado 80535).

21-24 January, **Research on the Environmental Fate and Effects of Drilling Fluids and Cuttings,** Florida (1629 K Street, NW Suite 700, Washington D.C. 20006).

4-6 March, **Petroleum Geology of the Continental Shelf of North-West Europe,** London (The Institute of Petroleum, 61 New Cavendish St, London W1, UK).

17-18 March, **Modelling Dispersion of Transport Pollution,** Cambridge (The Institute of Mathematics and its Applications, Maitland House, Warrior Square, Southend-on-Sea, Essex, UK).

23-26 March, **EURIM 4,** Brussels (Conference Organiser, Aslib, 3 Belgrave Square, London SW1, UK).

24-27 March, **Magnetic Fluids,** Florida (Dr M. Zahn, Dept of Electrical Engineering, University of Florida, Gainesville, Florida 32611).

8 April, **Doping in Sport,** London (Dr D. Simpson, Analysis for Industry, Factories 2/3 Bosworth House, High St, Thorpe-le-Soken, Essex, UK).

8-12 April, **World Biomaterials Congress,** Baden (Mrs E. Maurer, Medical Academy of Vienna, Alser StraBe 4, A-1090 Vienna, Austria).

9-11 April, **Annual Chemical Congress,** Durham (Dr J.F. Gibson, The Chemical Society, Burlington House, London W1, UK).

14-17 April, **Low Energy Ion Beams-2,** Bath (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

15-18 April, **Communications Equipment and Systems,** Birmingham (IEE, Savoy Place, London WC2, UK).

21-25 April, **2nd International Congress on Phosphorous Compounds,** Boston (IMPHOS, 8, rue de Penthievre, 75008, Paris, France).

29 April - 1 May, **Effective Use of Electricity in Buildings,** London (IEE Conference Dept, Savoy Place, London WC2, UK).

How Britain runs its science

This highly successful chart, which appeared in Nature 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US $1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

APPOINTMENTS VACANT

CHURCHILL HOSPITAL RESEARCH INSTITUTE (University of Oxford)

Vacancies exist for two RADIOBIOLOGISTS

in an expanding research group that is examining the biological effects if ionising radiations on a number of normal tissues and organs. These investigations are primarily aimed at improving the treatment of malignant disease by radiotherapy with both conventional photon therapy and fast neutrons. Post suitable for persons with higher degree or equivalent research experience. Responsibilities will depend on the interests and experience of the successful applicants although preference will be given in the case of one vacancy to someone with a qualification in Physics or experience in radiation dosimetry.

Further details can be obtained from Dr J W Hopewell, Churchill Hospital, Research Institute, Headington, Oxford, to whom application should also be sent with the names of two referees by 20th August, 1979. 2670(A)

UNIVERSITY OF WISCONSIN — MADISON

DEPARTMENT OF BACTERIOLOGY

FACULTY POSITION

ASSISTANT PROFESSORSHIP

Available 1980. Applicants with research interests related to host-parasite or cell-cell interactions and a broad background in general microbiology will be considered. Teaching responsibilities could include development of a modern course dealing with interactions between micro-organisms and higher organisms. Individuals with postdoctoral training are invited to send their vitae, most significant reprints, a short statement of projected research plans and the names of three references to Dr J Gregory Zeikus, Department of Bacteriology, University of Wisconsin, 1550 Linden Drive, Madison, WI 53706. An affirmative action/equal opportunity employer. Deadline 1 November 1979. W247(A)

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PATHOLOGY

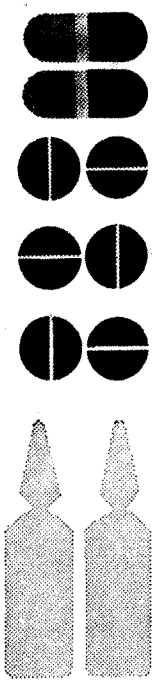
MICROBIOLOGIST -RESEARCH ASSISTANT.

A vacancy exists for a graduate research assistant in a project to investigate Chlamydia and their role in genital infection. The person appointed will be expected to take a major part in developing immunological methods for detecting chlamydial antigens and antibodies. Work will involve growth of chlamydia in tissue culture, purification, raising antisera and their use in recently developed tests. The project is for 2 years under Professor R.R.A. Coombs. Research experience is essential preferably in virology and/or immunology. Preference will be given to candidates with a PhD. The age range is 24-26 the salary £4,232 to £4,776.

Applications in writing to The Superintendent, Department of Pathology, Tennis Court Road, Cambridge, giving the names and addresses of two referees. 2686(A)

UNIVERSITY OF CALIFORNIA San Francisco

DEPARTMENT OF PHARMACEUTICAL CHEMISTRY



TWO POSTDOCTORAL POSITIONS

(i) A position is available immediately for study of liposomes as *in vivo* drug carriers. Experience in biochemistry, physiology or pharmaceutics desirable.

(ii) A position is available immediately for study of drug interactions at the metabolic level using a perfused liver system. Experience in analytical techniques, medicinal chemistry and/or pharmaceutics desirable.

Salary range: $13,000 to $15,000 for one to two years.

Send résumé, summary of past research and names of two references to Dr C Anthony Hunt, Department of Pharmaceutical Chemistry, S926-S, University of California, San Francisco, CA 94143. W258(A)

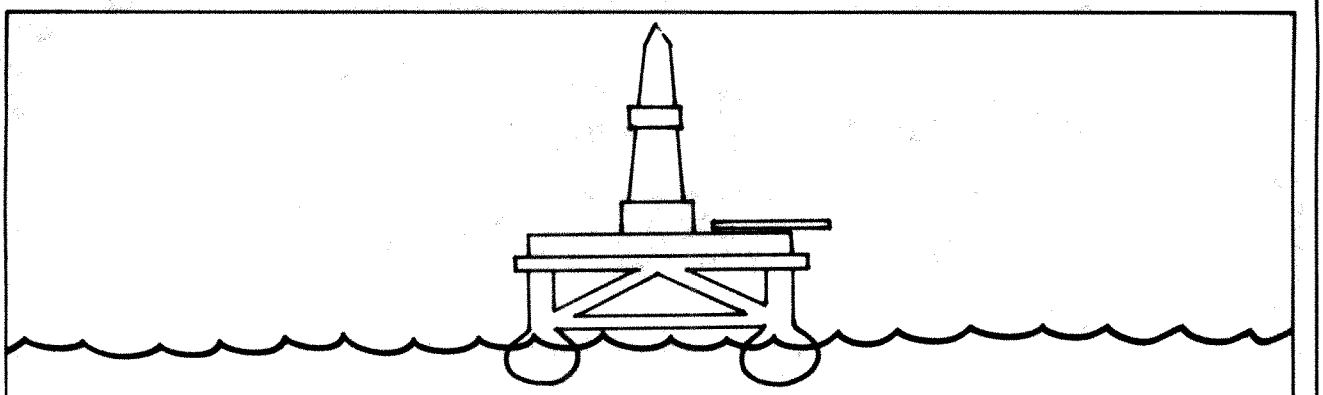
Pharmacologists

Following the appointment of Professor D. W. Straughan BSc, PhD, MB, LRCP, MRCS, as Director of Pharmacology, the Greenford Division of Glaxo Group Research Limited is expanding its research programme directed towards the development of new drugs acting on the central nervous system. Several vacancies exist for young and enthusiastic pharmacologists with a good understanding of current concepts relating to the functioning of neuro-transmitter systems and the effects of psycho-active drugs on them.

It is intended that some positions will be filled by new graduates with good degrees who wish to develop their interests in these fields, but there will also be opportunities for people with some previous research experience, particularly of techniques used in neurochemistry, behavioural pharmacology or neurophysiology.

We offer competitive salaries and excellent conditions of employment, including pension and bonus schemes, a subsidised cafeteria and a sports and social club.

Please write, or telephone, for an application form to: Mrs C. A. Carter, Personnel Officer, Glaxo Group Research Limited, Greenford Road, Greenford, Middlesex.
Tel: 01-422 3434, ext. 11, quoting ref: U/273.



Glaxo Group Research Ltd.

THE UNIVERSITY OF THE SOUTH PACIFIC

Applications are invited for the post of SENIOR LECTURER/ LECTURER IN AGRICULTURAL ECONOMICS (POST 79/75).

This post relates to the area of agricultural macroeconomics, or the economics of agriculture as an industry. Qualification should be a masters degree or higher with specialization in agricultural economics with several years of teaching and research experiences in this general area preferably in developing countries. Salary scales Senior Lecturer: F$11960 to F$14135 pa Lecturer: F$8175 to F$11563 pa (£1 sterling = F$1.81). The British Government may provide salary supplementation in the range £1,842 to £2,796 pa (sterling) for married appointee and £444 to £1,164 pa (sterling) for single appointee (reviewed annually and normally free from tax) and provide childrens' education allowance and holiday visit passages. Family passages; 15% gratuity of basic salary superannuation scheme; appointment allowance; partly furnished accommodation at a maximum rental of 12½% of salary (under review); 3 year contract. Detailed applications (2 copies) with curriculum vitae and naming referees to be sent direct to the Registrar University of the South Pacific, P O Box 1168, Suva, Fiji, by 7 September 1979. Applicants resident in the UK should also send one copy to Inter-University Council 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 2648(A)

Exploration Geologists & Geophysicists

Upgrade your prospects

A further expansion in North Sea Oil exploration is just beginning and our client, a major international oil company, is about to expand on their already substantial interests in this oil province.

Being the expert you undoubtedly are, you possess the specialist knowledge our client seeks for further development of their challenging oil and gas exploration and development programmes. May we assume you are interested? Then let us tell you more.

From the impressive results already achieved, our client is recognised as being at the forefront of North Sea exploration techniques and integrated geological/geophysical sub-surface interpretation. As a major operator with substantial interests both on and offshore, they are now expanding to embrace a number of new projects.

Here is a unique opportunity to apply your own experience and accumulate further knowledge of exploration techniques with one of the foremost exploration groups in the world. Initially, we are talking about working on U.K. acreage, but international careers are available depending upon your own efforts and personal ambition. Opportunities for career advancement into senior management positions both at home and overseas exist for individuals showing outstanding creativity and personal achievement.

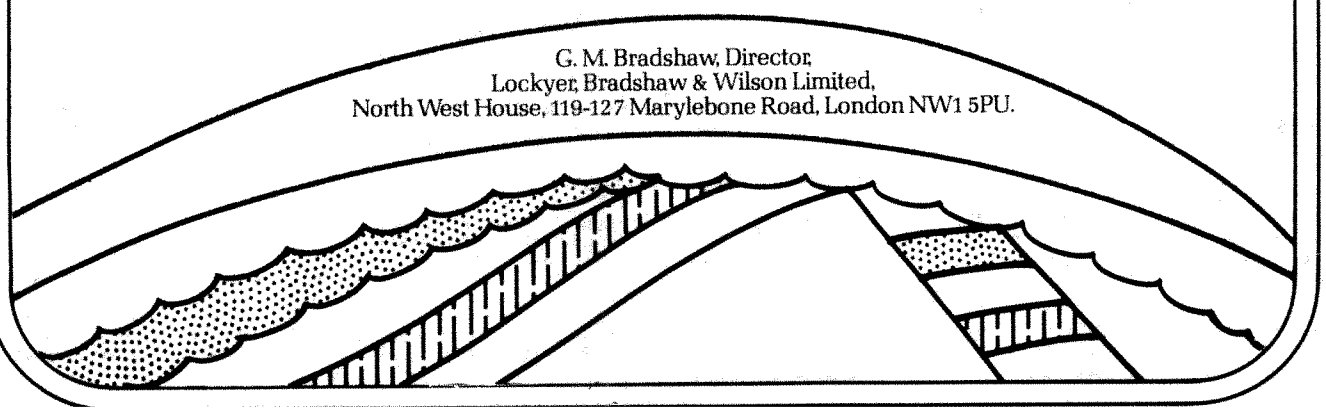
To meet our client's immediate recruitment programme, applications are invited for the following London based positions.

OPERATIONS

Geology Graduates with experience as Mud Loggers, Data Engineers, Consultant Wellsite Geologists or with oil company experience that has included wellsite work.

INTERPRETATION

Graduate Geologists and Geophysicists with substantial sub-surface interpretation experience.



The financial package offered by our client indicates their high regard for active, highly professional exploration specialists.

Please write (quoting ref. CRS 124) with a full C.V. to the address below advising of any companies to whom your application should not be referred. Alternatively an application form can be obtained by telephoning us on 01-402 4525 (between 09.30 and 17.00, Monday to Friday), or Sunday 22nd July ONLY on either 01-527 4720, 01-660 6289 or 01-504 2084.

FISONS 1978

PHARMACEUTICAL DIVISION

UNIVERSITY OF OXFORD

Sir William Dunn School of Pathology

RESEARCH ASSISTANT

Grade 1A

Salary £4,232 to £7,145

Applications are invited for a Research Assistant supported by the Cancer Research Campaign, to assist with research into the biochemical mechanisms of virus growth. Experience with mammalian tissue culture would be an advantage. Applicants should possess a degree or equivalent qualification.

Applications, in writing, together with the names and addresses of two referees, to the Administrator, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE. 2643(A)

UNIVERSITY OF READING

DEPARTMENT OF SOIL SCIENCE

Applications are invited for a Lecturership in Soil Science with responsibility in soil physics or microbiology or soil biochemistry.

The appointment will be made within the first five points of the Lecturer salary scale (£4,333 to £5,488 per annum).

The person appointed should take up duties on 1 January 1980.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, by whom applications should be received not later than 30 September 1979. 2715(A)

NEWCASTLE AREA HEALTH AUTHORITY (TEACHING)

NEWCASTLE GENERAL HOSPITAL

TWO MEDICAL LABORATORY SCIENTIFIC OFFICERS

required in Muscular Dystrophy Group Laboratories, Regional Neurological Centre —

(1) To assist with development of tissue culture techniques for study of muscle and nervous tissues as part of a research programme which involves several scientific disciplines. Experience of tissue culture and sterile techniques and a knowledge of electron microscopy an advantage.

(2) To be involved in immunological investigation of neuromuscular diseases as part of a multi-disciplinary research programme. Experience of HLA-typing, lymphocyte transformation and RIA techniques would be an advantage.

Candidates must be registered.

Further information from Mr. J. J. Fulthorpe, Senior Chief MLSO, tel. 0632 738811 ext. 573.

Applications, with names and addresses of two professional referees, to Western Sector Administrator, Newcastle General Hospital, Newcastle upon Tyne NE4 6BE, by 17th August. 2661(A)

COMMONWEALTH AGRICULTURAL BUREAUX

Vacancy for

SCIENTIFIC INFORMATION OFFICER

at the

COMMONWEALTH FORESTRY BUREAU

Commonwealth Forestry Institute

South Parks Road, Oxford, OX1 3RD

Duties of post: The scrutiny of technical literature, selection and preparation of abstracts in many subjects related to forestry or forest products (this may involve visits to outside libraries), indexing, preparing for the press and dealing with technical enquiries.

Flexible working hours are based on 37 hours per week. Applicants wishing to work 18½ hours per week, with appropriate adjustments of salary, etc, will be considered.

Qualifications: Applicants should be graduates in forestry or in a biological science or in a relevant branch of physical or engineering science. Strong preference will be given to candidates with a good reading knowledge of French, German or Russian.

Salary: In the range £2,998 to £5,448 (under review) and a compensatory allowance (taxable but not superannuable) of 3.3% to offset personal contribution to Superannuation. Starting salary according to qualifications, experience and age. Promotion to higher scales on merit.

Application forms and full particulars from the Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN. Closing date for applications: 31 August 1979. 2694(A)

UNIVERSITY OF KHARTOUM

Sudan

Applications are invited for the post of

CHIEF TECHNICIAN/ SENIOR TECHNICIAN/ TECHNICIAN

in the

HYDROBIOLOGICAL RESEARCH UNIT

Faculty of Science

Salary under review (exclusive of expatriate allowance); Chief Technician £S1,530 to 1,905 pa, Senior Technician £S1,330 to 1,580 pa, Technician £S1,030 to 1,280 pa (£S1 = £1.31 sterling). The British Government may supplement salaries of Senior and Chief Technician in range £4,140 to 4,284 pa (sterling) for married appointee or £2,076 to 2,226 pa (sterling) for single appointee (reviewed annually and normally free from tax) and provide childrens education allowances and holiday visit passages (presently under review). It is unlikely that there will be supplementation for technician grade. Family passages; baggage allowance; accommodation; car loan; superannuation scheme; various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Personnel Secretary, University of Khartoum, P O Box 321, Khartoum, Sudan by 23 August, 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 2647(A)

Behringwerke

We are a wellknown firm of the pharmaceutical industry belonging to the HOECHST-Group with headquarters in the university town of Marburg/Lahn.
Mainly concerned with developing new preparations for therapy and prophylaxis we are looking for a young (male or female)

Scientist/ Virologist

(physician, biochemist, biologist or chemist)

for our virological research department, who should possess a degree preferably in a virological or immunological subject. Relevant experience in this field and general practice in a virological institute are required.
Applicants should be at least 30 years old. Good knowledge of English is essential.
Ability to work in a team is expected.
Financial and social benefits will be offered in accordance with the importance of this position.
Further particulars may preferably be discussed personally.
Please send your application with detailed documents to

P.O.B. 1140 D-3550 Marburg 1 Fed. Rep. Germany

BEHRING INSTITUT

W250(A)

OXFORD UNIVERSITY

Sir William Dunn School of Pathology

NUCLEIC ACID BIOCHEMIST

Applications are invited for a post-doctoral research position, funded by the Cancer Research Campaign. The research concerns the preparation and transcription of superhelical templates derived from the nuclear DNA of human cells. Experience in enzyme purification (for the preparation of DNA gyrase and the relaxing enzyme) or the assay of specific transcripts is desirable, but not essential.

The appointment, starting as soon as possible after 1st October 1979, is likely to be for 2 years. The salary will be at an appropriate point on the University 1A scale, £4,232 to £7,145.

Applications, including curriculum vitae and the names and addresses of 2 referees, should be sent as soon as possible to Dr P R Cook, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE. 2625(A)

UNIVERSITY OF NORTH CAROLINA, Chapel Hill

DEPARTMENT OF ZOOLOGY

CHAIRPERSON

The Department of Zoology, University of North Carolina at Chapel Hill, invites applications for the position of

PROFESSOR AND CHAIRPERSON.

The Department's twenty-five faculty members have broad interests and actively participate in four interdepartmental programs. Candidates must have distinguished professional records and must be able to provide dynamic, unifying leadership. Appointment is to the rank of tenured professor; salary is fully negotiable. Nominations and applications including curriculum vitae and the names of at least three references should be sent prior to November 1, 1979 to: Professor C.F. Christman, 106 Rosenau Hall, 201H, University of North Carolina, Chapel Hill, NC 27514. The University of North Carolina is an affirmative action, equal opportunity employer. W252(A)

EUROPEAN JOURNAL OF BIOCHEMISTRY

Applications are invited from graduates in biochemistry, PhD preferably, for the post of

EDITORIAL SECRETARY

at the journal's office in Liège.

Salary will be around £5,800 net per annum, or more according to special experience. Applicants should preferably be nationals of the member states of the European Economic Community.

Applications, which should include the name of at least one referee and complete curriculum vitae, should be sent as soon as possible to Professor Claude Liébecq, 69/054 Boulevard de la Constitution, B-4020 Liège, Belgium. 2533(A)

Junior/basic grade MLSO required to work in routine Histopathology Laboratory. Post entails routine and research work presenting good opportunity for those wishing to take IMLS special examination. Applicants for Junior post should have 5 "0's" including English, Maths and 2 relevant sciences or 2 relevant "A's". Applicant for basic MLSO should have HNC MLS. Salary on MLSO scales.

Apply quoting reference TP1 to The Secretary, Cardiothoracic Institute, Fulham Road, London, SW3 6HP, stating age, experience, qualifications and giving names of 2 referees. Closing date 31/8/79. 2685(A)

ASSISTANT RESEARCH CHEMIST Department of Internal Medicine Martinez VA Hospital, Martinez, CA PhD with minimum of two years' post doctoral experience in the synthesis of pedtides and the operation of an HPLC thorough knowledge of enzyme kinetics and experience in protein purification. An equal employment opportunity/affirmative action employer. Send cv bibliography and references to Corey Largman PhD, Department of Medicine Martinez VA Hospital, 150 Muir Road Martinez, CA 94553. Position to remain open until October 31, 1979. W259(A)

PRINCIPAL SCIENTIST

MICROBIOLOGY AND FERMENTATION

The Brewing Research Foundation, established to carry out co-operative research for the brewing industry in the UK and abroad, wishes to appoint a *Principal Scientist* as head of its *Microbiology and Fermentation Section*.

Candidates, aged between about 30 and 45 should have good academic qualifications and appropriate research experience. The successful candidate, who will be responsible to the Director for the development and organisation of the Section's research programme, will also be expected to carry out his own personal research.

The post offers an excellent opportunity for an alert and ambitious researcher to make a name in this important part of the food and drink industry.

The Foundation provides good conditions of service; the initial salary will be within the range £8,500 to £11,000.

Applications giving details of education, experience, papers etc should be sent to the Assistant Director, Administration and Finance, Brewing Research Foundation, Lyttel Hall, Nutfield, REDHILL, Surrey RH1 4HY. 2671(A)

BIOGEN S.A.

a young company engaged in basic and applied research in the field of molecular biology and microbiology, and with the objective of utilizing the potential of genetic engineering for the production of substances of commercial and medical interest in such areas as health care, agriculture and energy, is inviting applications from

SENIOR AND JUNIOR SCIENTISTS

with experience in molecular biology, nucleic acid biochemistry and microbiology,

for its **Research Laboratory in Geneva,**

Switzerland.

Excellent working conditions, in close contact with leading scientists from Europe and the US.

Salary scale: Group Leaders = SFr 60-85,000, Research Associates = SFr 35-55,000.

Applicants with real interest in both basic research and its applications should send their curriculum vitae (with a description of previous experience and a list of publications) to BIOGEN Laboratory, 3 Route de Troinex, 1227 Geneva, Switzerland. W248(A)

TECHNICIAN

Department of Viral Products

required to work in a laboratory concerned with research into the development and standardisation of vaccine for Poliomyelitis.

Candidates should possess or be studying for an HNC or equivalent in one of the biological sciences. Experience in virology or cell culture would be an advantage although training will be provided.

Salary, depending on qualifications and experience, on the scale £2,892 to £5,034 (pay award pending) including London Weighting, plus superannuation benefits.

Please write or telephone for further details, and an application form, to the Personnel Officer, National Institute for Biological Standards and Control, Holly Hill, London NW3 6RB. Tel: 01-435 2232, ext. 200, quoting Reference VP/103.

NIBSC

National Institute for Biological Standards and Control

2645(A)

UNIVERSITY COLLEGE OF SWAZILAND

Applications are invited for the post of

LECTURER in the DEPARTMENT OF STATISTICS

Applicants should possess a Master's degree or a PhD in Mathematics/Statistics. Experience in Operational Research and/or Quality Control would be an additional recommendation. The appointee will be required to lecture to undergraduates in introductory and theoretical statistics and to be capable of carrying out independent research.

Salary scale: E5,940 to 7,876 pa (£1sterling = L1.86). The British Government may supplement salary in range £1,650 to 2,184pa (sterling) for married appointee or £408 to 960 pa (sterling) for single appointee (reviewed annually and normally free from tax) and provide children's education allowances and holiday visit passages. Family passages; short-term contracts for two or four years for expatriates. If appointment is for a limited period, a 25% gratuity is paid in lieu of superannuation for the first two years of service; 27½% for the second two years. A 10 per cent Inducement Allowance is payable to expatriates not qualifying for supplementation from other sources. Education allowance; medical aid; accommodation; biennial leave.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Registrar, University College of Swaziland, Private Bag, Kwaluseni, Swaziland by 27 August 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 2705(A)

THE SOUTH STAFFORDSHIRE WATERWORKS COMPANY

WATER QUALITY DEPARTMENT

CHIEF ASSISTANT CHEMIST

Location: Initially at Lichfield, permanent location at new Central Laboratory in Walsall, West Midlands.

Salary: NJC Water Service Staffs Grade 10, Range £7,776 to £8,352 p.a. (currently under review).

Applications are invited for the above post from professionally qualified chemists having a good honours degree in an appropriate scientific subject and preferably with experience of bacteriological work and procedures. Appropriate administrative experience will be an advantage.

The successful candidate will be required to assist the Chief Chemist and Deputy Chief Chemist in the general operation of the department and initially will be directly responsible for the technical and administrative co-ordination of the Company's laboratory and the establishment of a computerised water quality data bank. Detailed technical competence is required in current methods of water analyses, including advanced instrumental techniques, and the ability to prepare clear and concise technical reports.

The laboratory performs the full range of analytical functions required to satisfy the bacteriological, biological and visible wholesomeness of a large water supply. Modern analytical instrumentation is available for the performance of these functions and the range is to be further extended upon completion of new laboratories presently under construction.

Appropriate transport arrangements will be provided together with the payment of approved relocation expenses where the successful applicant is required to move house.

Applications, giving full details of training and experience, together with the names of two referees should be sent not later than 27th August, 1979 to:-

James Lamont BSc MICE, General Manager, The South Staffordshire Waterworks Company, 50 Sheepcote Street, Birmingham B16 8AR. 2659(A)

SIMON FRASER UNIVERSITY

Burnaby, British Columbia Canada

DEPARTMENT OF BIOLOGICAL SCIENCES

ENTOMOLOGIST

Applications are invited for a tenure-track position as an Assistant Professor in entomology. The successful applicant will be expected to develop a strong research program and to participate in the teaching program at both the undergraduate and graduate level including the Master of Pest Management Program. Candidates must have a PhD degree in entomology or related subject. The position is available immediately, subject to budgetary approval. The initial appointment will be for a period of 2 years, renewable. The salary scale is under revision; the current salary base for the Assistant Professor rank is $18,604 per annum.

Applications should include an up-to-date curriculum vitae, a brief statement of research interests and goals, and reprints of published research. Applicants should request a confidential assessment of their research and teaching ability from three referees, to be forwarded directly to Dr M Mackauer, Chairman, Dept of Biological Sciences, Simon Fraser University, Burnaby, BC, Canada V5A 1S6. Deadline for receipt of applications is 15 September 1979 or when position filled. W240(A)

UNIVERSITY OF ZAMBIA

Applications are invited for the posts of

PROFESSOR/
ASSOCIATE PROFESSOR/
SENIOR LECTURER/
LECTURER

in the following posts in the School of Agricultural Sciences. Soil Science (2 posts). Soil Physics (Irrigation and Drainage) Soil Science (Chemistry and Fertility). Agricultural Engineering (1 post). Agricultural Mechanization, Civil Engineering in developing countries. Rural Economy and Extension Studies (1 post). Agricultural Extension and Rural Sociology, Economics and Psychology.

For all these posts applicants are required to have a PhD and considerable University level teaching experience with research and publications in the areas of their specializations.

Salary Scales: Professor K8,616 to 9,135 pa, Associate Professor K8,232 to 8,616 pa, Senior Lecturer K7,608 to 8,016 pa, Lecturer K5,904 to 7,608 pa (£1 sterling = K1.70). The British Government may supplement salaries in range £2,922 to 5,952 pa (sterling) for married appointees and £930 to 3,366 pa (sterling) for single appointees (reviewed annually and normally free from tax) and provide childrens education allowances and holiday visit passages. Family passages; baggage allowance; superannuation scheme; accommodation; overseas leave; various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Registrar, University of Zambia, PO Box 2379, Lusaka, Zambia by 24 August, 1979. Applicants resident in the UK should also send one copy to Inter University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further details may be obtained from either address. 2700(A)

UNIVERSITY OF ZAMBIA

Applications are invited for the post of

SENIOR LECTURER/
LECTURER IN BIOLOGY

SCHOOL OF NATURAL SCIENCES

Special reference to Biochemistry required. Research interest desired and preferred in Comparative Plant and Animal Metabolism, Enzymology or Morphogenetic Studies. Applicants should have PhD or equivalent plus university level teaching experience in Enzymology studies. Appointee will be responsible for the teaching of general physiology and biochemistry course as well as conducting an advanced biochemistry course in the final year of the BSc programme. Post tenable as soon as possible. Salary scales: Senior Lecturer K7,608 to 8,016 pa, Lecturer K5,904 to 7,608 pa (£1 sterling = K1.70). The British Government may supplement salary in range £2,922 to 4,350 pa (sterling) for married appointee and £930 to 1,968 (sterling) for single appointee (reviewed annually and normally free from tax) and provide childrens education allowances and holiday visit passages. Family passages; baggage allowance; contract 2-5 years; contributory superannuation scheme; accommodation; various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Registrar, University of Zambia, PO Box 2379, Lusaka, Zambia by 27 August 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 2699(A)

University of Jos
JOS, NIGERIA

Applications are invited from suitably qualified candidates to fill the following vacant posts:—

POSTS

A. Faculty of Medical Sciences

Professor/Reader/Senior Lecturer/Lecturer I & II in the following fields:—
1. Medicine, 2. Paediatrics, 3. Pharmacology & Therapeutics, 4. Psychiatry, 5. Surgery, 6. Obstetrics and Gynaecology, 7. Community Medicine, 8. Anaesthesia, 9. Microbiology, 10. Chemistry Pathology, 11. Pathology, 12. Haematology and Blood Transfusion, 13. Anatomy.

QUALIFICATIONS

PROFESSOR/ READER

The candidate who should have a post-graduate qualification registerable with the Nigeria Medical Council, should be an authority in his field and should have several years' experience in his area of competence.

SENIOR LECTURER/ LECTURER I & II

Candidates for 1, 2, 3 and 4 should possess an MRCP or similar post-graduate qualification. Candidates for 5 should possess an FRCS. Candidates for 6 should possess an MRCOG. Candidates for 7 should possess DPH/MPH and possession of an MRCP or MFCM would be an advantage. Candidates for 8 should possess an FFARCS or DA. Candidates for 9, 10, 11 and 12 should possess an MRC Path, a PhD or equivalent qualification. Candidates for 13 should possess an MS, MSc, or PhD (Anatomy). In the case of Senior Lecturer, candidates should generally possess not less than 5 years' experience in research and teaching in the speciality — 3 years' experience for Anatomist. Possession of a PhD would be an advantage as would training and experience in any sub-speciality in these fields.

B. Faculty of Natural Sciences

Professor in Chemistry and Zoology; Senior Lecturer/Lecturer I & II in the following:—
1. Mathematics with specialisation in Statistics, Differential Equations and Functional Analysis.
2. Botany in the fields of Plant Taxanomy, Plant Anatomy, Microbiology (including Bacteriology), Crytopatic Botany and Hydrobiology.
3. Organic Chemistry, Inorganic Chemistry and Analytical Chemistry.
4. Geology.
5. Zoology.

QUALIFICATIONS

For all posts above, candidates should possess Higher Degrees from recognised Universities with considerable teaching experience. A PhD will be an advantage. For Professors, candidates must have established a reputation in research in their field of specialisation and must have demonstrated capability in initiating and directing research activities at a higher level.

SALARIES

Professors — GL 16 — N11,568 × 526 — N12,720 pa. Reader — GL 15 — N10,296 × 516 — N11,238 pa. Senior Lecturer — GL 13 — N8,064 × 320 — N9,024 pa. Lecturer Grade I — GL 12 — N7,404 × 216 — N8,052 pa. Lecturer Grade II — GL 10 — N5,760 × 162 — N6,732 pa.

CONDITIONS OF SERVICE

Successful candidates will be on probation for the first two years and afterwards confirmed to retiring age if their services are considered satisfactory. Other fringe benefits include pension scheme, part-furnished accommodation or housing allowance in lieu of accommodation. Twenty five per cent contract addition is payable to all expatriates.

METHOD OF APPLICATION

Candidates should send 4 copies of their CV to the Principal Assistant Secretary (Recruitment), Nigerian Universities Office, 180 Tottenham Court Road, London W1P 9LE as soon as possible.

The CV should give the following information: Post desired, full name, date and place of birth, nationality, permanent address, telephone number (if any), current postal address and telephone number (if applicable), marital status, number and ages of children, educational institutions attended with dates, full qualifications plus copies of certificates, previous employment with dates, present employment with dates and salary, list of publications, names and addresses of three distinguished scholars in relevant field as referees, two passport photographs of self. Candidates are advised to request their referees to forward references on them directly to the London Office.

CLOSING DATE: 16th August 1979. 2697(A)

UNIVERSITY OF OXFORD
In association with
St Edmund Hall

UNIVERSITY
LECTURESHIP IN
PHYSIOLOGY

The University proposes to appoint as soon as possible a lecturer in the Laboratory of Physiology. Applications are invited from candidates in all fields of Physiology but the successful candidate will be expected to teach in the fields of either Visual or Renal or Gastro-intestinal Physiology. Salary according to age on the scale £4,232 to £9,000. The post may be held in association with a tutorial fellowship at St Edmund Hall.

Further enquiries concerning both the lectureship and the fellowship should be addressed to the Professor-elect, Dr C B Blakemore, c/o the Administrator, University Laboratory of Physiology, Parks Road, Oxford, to whom applications (8 copies, one in the case of overseas candidates) together with the names of three referees should be sent by 30 September 1979. 2644(A)

THE NATIONAL INSTITUTE FOR HIGHER EDUCATION, LIMERICK

Further expansion of the Institute is taking place at undergraduate and postgraduate levels within the extensive complex of World Bank-financed facilities which have been commissioned as part of the first phase of development of the Riverside campus.

APPLIED MATHEMATICS Lecturer AS4-010

Person appointed will contribute to the development and operation of existing and new courses to degree and postgraduate level. Applicants should have demonstrated expertise in the applications of mathematics and have special competence in the area of numerical analysis. A postgraduate qualification in a relevant area is desirable.

SALARY SCALE: £6,901 to £8,766 p.a. (under review)

Application forms which are available from the Personnel Office, The National Institute for Higher Education, Limerick, Ireland, should be completed and returned *by 24th August, 1979*. 2668(A)

Project Leader

Gas Chromatograph Development

Pye Unicam, part of the multinational Pye/Philips Group of Companies, are leading manufacturers of scientific and analytical instrumentation.

Due to continued expansion, we urgently need an experienced Physicist or Physical Chemist/Engineer. This is a senior position and responsibilities will include contributing to our development programme, carrying out necessary fundamental design studies and obtaining experimental confirmation of their effectiveness.

Candidates should have broad knowledge of the design and use of Gas Chromatographs or related instruments. Several years design experience is essential along with the relevant academic qualifications.

Future prospects are excellent with the successful applicant subsequently becoming responsible for the progress of a new instrument through its development phase, by co-ordinating the design imputs of the other members of the team.

Along with a competitive salary, we offer appreciable fringe benefits, including flexible working hours and group pension scheme.

Please write or telephone for an application form to:
Mrs Jane Wakelin, Personnel Officer. 2691(A)

UNIVERSITY OF KHARTOUM
Sudan

Applications are invited for the post of

PROFESSOR
in the
HYDROBIOLOGICAL RESEARCH UNIT
Faculty of Science

Salary (exclusive of expatriate allowance); £S6,933 pa (£S1 = £1.31 sterling). The British Government may supplement salary by £5,028 pa (sterling) for married appointee or £3,144 pa (sterling) for single appointee (reviewed annually and normally free from tax) and provide childrens education allowances and holiday visit passages. Family passages; baggage allowance; accommodation; car loan; superannuation scheme; various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Personnel Secretary, University of Khartoum, P O Box 321, Khartoum, Sudan by 23 August, 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 2646(A)

UNIVERSITY OF OXFORD

Departments of Pharmacology and Physical Chemistry

POSTDOCTORAL RESEARCH ASSOCIATE IN HIGH PRESSURE PHYSIOLOGY AND PHARMACOLOGY

A postdoctoral position is available for research related to diving and the effects of high pressure on man and animals, in an interdisciplinary research team conducted by Prof. Sir William Paton and Dr E B Smith. A number of lines of research are being actively pursued, ranging from physical chemistry to human physiology. The successful candidate could work in any of these areas, although preference may be given to those interested in neuropharmacological approaches.

Applications, including statements of research experience and publications, with the names of two referees, should be sent as soon as possible to Prof Sir William Paton, Department of Pharmacology, South Parks Road, Oxford OX1 3QT. It is hoped to make an early appointment to enable the successful candidate to take up the post by 1 October 1979, although this need not rule out applicants wishing to start later. 2672(A)

THE UNIVERSITY OF BIRMINGHAM
FACULTY OF MEDICINE AND DENTISTRY
Department of Anatomy

RESEARCH ASSOCIATE/ FELLOW

Research Associate/Fellow required to join a multidisciplinary team to study the differentiation of skeletal muscle using monoclonal antibodies.

Candidates should be able to offer postgraduate qualifications or experience in Biochemistry or a related discipline. The post is supported for three years by the MRC, with a salary on the scale (to operate from 1st October 1979) £3,775 to £5,488 or £4,333 to £7,521 plus superannuation.

Your application (three copies) should include a curriculum vitae, details of experience and the names of two referees. Send it to the Assistant Registrar, Faculty of Medicine, University of Birmingham, Birmingham B15 2TJ by 24th August 1979, quoting reference RA/ANT/379 or talk to Dr S Salmons on 021-472 1301, ext 2093. 2665(A)

SENIOR BIOCHEMIST

This new post will be in the Biology Department of an international industrial firm, leader in cosmetics and hair products.

The applicants should have a PhD degree in Biochemistry and an experience in analysis and separation of proteins. He should have a good knowledge of biochemistry of keratin.

The position requires aptitude to scientific research and ability to lead a team of graduates and technicians.

The successful applicant will work under the direction of the head manager of the Biology Department. The salary will depend on experience.

The research centre is located north of Paris.

Ability to speak and write in English as well as a good working knowledge of French are necessary, other languages being a further asset.

For further information, please send curriculum vitae to L'OREAL — M. JEGO 1, avenue de St Germain — 93601 AULNAY SOUS BOIS — FRANCE.
W261(A)

Royal Observatory, Edinburgh

PROFESSIONAL AND TECHNOLOGY OFFICER

GRADE 1

The Technology Unit at the Royal Observatory has a vacancy for an engineer at PTO I level. The Unit is responsible for research, development and manufacture of a wide range of instrumentation for the National Facilities run by the Observatory, which include the 1.2 metre Schmidt Telescope in Australia, the 3.8 metre Infrared Telescope in Hawaii and the COSMOS Measuring Machine at Edinburgh.

The successful candidate will be responsible for applications of infrared and optical solid-state and vidicon-type detectors to the recording of extremely low levels of radiation. Initially he/she will be involved in the development and construction of a cooled 10 micron array spectrometer, operating with As doped silicon diodes.

The applicant should be a fully qualified engineer; possession of an advanced degree may be an advantage. Applicants will be required to describe successful results with solid-state or vidicon-type systems which they have developed.

Starting salary will be in the range £5,739 to £7,064 depending on age and experience. A non-contributory superannuation scheme is included.

SRC

Further details and application forms from The Personnel Officer, Royal Observatory, Blackford Hill, Edinburgh EH9 3HJ. Tel: 031 667 3321.

CLOSING DATE: 2 AUGUST 1979.

2604(A)

Pharmacologist

Bronchorespiratory Research

Roussel Laboratories is one of the leading pharmaceutical companies in the UK. A vital part of the international Roussel-Uclaf organisation, it researches, manufactures and distributes a range of important ethical pharmaceutical and allied products for use throughout the world.

We are currently developing a number of products within the bronchorespiratory area. We wish to intensify this research programme and need a suitably experienced pharmacologist to play a key role in this work.

Applications are invited from candidates qualifying this year for a PhD, preferably in respiratory pharmacology, but experience of research to PhD level in allied branches of pharmacology will be considered.

The salary is competitive and benefits include free BUPA and life insurance, a contributory pension scheme and generous assistance with relocation expenses where appropriate.

For further information and an application form, please telephone or write to Rosemary Curtis, Assistant Personnel Manager, Roussel Laboratories Limited, Kingfisher Drive, Covingham, Swindon, Wilts SN3 5BZ.
Telephone: Swindon (0793) 24411.

ROUSSEL

2692(A)

UNIVERSITY OF THE SOUTH PACIFIC

Applications are invited for the post of

PROFESSOR IN CHEMISTRY

(Post 79/72) tenable from January 1980. Applicants with a proven record of teaching, research and administrative experience in Chemistry are invited to apply. Preference will be given to candidates with academic interests in the general area of physical/inorganic chemistry, but applications from the organic/biochemical field will be fully considered. Experience in determining tertiary educational priorities in a developing country context would be an advantage. The Head of Chemistry has overall responsibility for the Chemistry component of teaching programmes which includes pre-degree courses, Dip. Ed., BSc., BSc + GCEd., B.Ed and B.Agr.* (*1st year only) degrees and for postgraduate work and regional extension courses. Staff may also be involved in consultancy, research and development projects for associated University Institutes. Salary scale: F$19,008 to F$20,420 p.a. (£1 sterling = F$1.81). The British Government may supplement salary by £2,700 p.a. (sterling) for married appointee or £948 p.a. (sterling) for single appointee (reviewed annually and normally free from tax) and provide childrens' education allowances and holiday visit passages. Family passages; baggage allowance; 15% gratuity; superannuation scheme; accommodation at 12½% of salary (under review); 3 year contract — exceptionally, candidate may be considered for shorter period. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Registrar, University of the South Pacific, Box 1168, Suva, Fiji by 17 August 1979. Applicants resident in the UK should also send one copy to Inter University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further details may be obtained from either address. 2663(A)

UNIVERSITY OF EDINBURGH

DEPARTMENT OF MICROBIOLOGY

Applications are invited from

CHEMISTS OR BIOCHEMISTS

for two post-doctoral posts to work on a study of the effect of temperature, pH, etc on the physical properties of microbial polysaccharides. This three-year project is sponsored by the Department of Energy. Both positions are on Scale 1A within the range £4,333 to £5,199. For one position, some postdoctoral experience would be helpful, while the second would suit someone with interests in "methodology".

Further details from and applications to: Dr I W Sutherland, Department of Microbiology, Edinburgh University, West Mains Road, Edinburgh EH9 3JG. Please quote reference 5041. 2669(A)

UNIVERSITY OF OXFORD

DEPARTMENT OF CLINICAL BIOCHEMISTRY

TECHNICIAN

required for research into regulation of the pyruvate dehydrogenase complex. The post is available initially for two years from October 1. Applicants should have a degree in biochemistry (or a related subject) or possess suitable laboratory experience. Starting salary up to £4,047 per annum.

Applications including the names of two referees to Professor P. J. Randle, Department of Clinical Biochemistry, John Radcliffe Hospital, Headington, Oxford, OX3 9DU. 2578(A)

TECHNICIAN

A Technician is required to assist in a programme of work on neurotoxicity. Training in biochemistry is essential but some experience in physiological techniques would be an advantage. Qualifications: Degree HNC or equivalent. Salary on scale of £3,261 to £4,680 plus London Weighting of £354.

Apply in writing giving curriculum vitae to Mr V. H. Parker, Toxicology Unit, MRC Laboratories, Woodmansterne Road, Carshalton, Surrey.

MRC Medical Research Council

2598(A)

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHYSICS

POSTDOCTORAL RESEARCH ASSISTANT

The University of Leicester is embarking on a project, supported by the Royal Observatory, Edinburgh, to develop focal plane instrumentation for the 3.4 m United Kingdom Infra Red Telescope (UKIRT). A post exists for a research assistant to join the project, firstly to investigate applications of multi-element CID/CCD imaging detectors in infra-red astronomy; secondly to participate in the development of a multi-element photometer and a low resolution spectrometer for UKIRT and thirdly, through the use of one or both of these instruments, to take part in astronomical observations using UKIRT and/or the Tenerife 1.5 m telescope. Research experience with solid state photon detectors, and low noise signal handling methods, would be an advantage, especially if combined with an interest in infra-red astronomical techniques.

The post will be for 3 years. Salary will be within the range £4,232 to £4,776 per annum (£4,333 to £4,910 from October 1 1979) depending upon qualification and experience. Superannuation is under U.S.S. conditions.

Applications, together with the names and addresses of two referees, and a curriculum vitae, should be sent to Professor K.A. Pounds, Department of Physics, University of Leicester, LE1 7RH by August 15th 1979. Further particulars about the project are available on request. 2664(A)

OXFORD UNIVERSITY

PHYSICAL CHEMISTRY LABORATORY

APPOINTMENT OF POST DOCTORAL RESEARCH ASSISTANT

Reactions of atoms and radicals

Applications are invited from chemists or physicists to work on a laser flash photolysis method for measuring the rates of reactions between atoms and radicals, using absorption and resonance fluoresence techniques.

The appointment is for 2 years in Research support grade 1A with membership of U.S.S. Starting salary is up to £4,776.

Applications with curriculum vitae and the names of two referees should be sent as soon as possible to Dr M.J. Pilling, Physical Chemistry Laboratory, South Parks Road, Oxford OX1 3QZ. 2677(A)

CAMBRIDGESHIRE COLLEGE OF ARTS AND TECHNOLOGY

LECTURER IN BIOLOGY

required from 1 October 1979 or as soon as possible thereafter to teach general biology at GCE 'A' level and TEC Certificate level. The ability to teach a specialist biological subject at HTEC/degree level would be an advantage. Applicants should be graduates, and the successful candidate will be expected to become involved in the research programme of the Science Department.

Salary: £3,480 to £5,992 starting point depends on qualifications and experience.

Forms and further details from: Head of Science Department, CCAT, Cambridge, CB1 2AJ. Forms to be returned by 17 August 1979. 2719(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEMONSTRATOR IN THE DEPARTMENT OF ENGINEERING MATHEMATICS

Applications are invited for a post of

DEMONSTRATOR

in the Department of Engineering Mathematics for a period of 3 years. The person appointed will be expected to have a good mathematics degree and preferably a higher degree, but applicants with a degree in other disciplines and good mathematical experience will be considered. It would be an advantage if the applicant were to have an interest in some aspect of engineering. The person appointed will be required to undertake tutorial work in mathematics, including statistics, for engineering students and there will be an opportunity to participate in some of the lecturing duties undertaken by the Department.

Salary will be at an appropriate point on the Grade 1B (Bar) scale: £3,689 to £5,321 per annum (£3,775 to £5,488 per annum from 1st October, 1979), according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar (F.P.) The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU with whom applications (2 copies), together with the names and addresses of 3 referees, should be lodged not later than 10th August, 1979. Please quote reference N. 2651(A)

KING'S COLLEGE LONDON

DEPARTMENT OF BIOPHYSICS

RESEARCH TECHNICIAN

Applications are invited for the post of Technician to work on Wellcome Trust-supported research on the mechanism and control of chromatin transcription. Experience in sub-cellular fractionation techniques, protein and nucleic acid biochemistry and restriction endonuclease mapping would provide useful background.

The appointment would be for one year in the first instance starting 1 September (or sooner). Salary on scale £3,455 pa to £3,860 pa or £3,998 pa to £4,580 pa (inclusive) according to qualifications and experience.

Applications with curriculum vitae and the names of two referees should be sent to Dr J Allen (Ref: 217825/N), Department of Biophysics, King's College London, 26-29 Drury Lane, London WC2B 5RL. 2666(A)

JOHN INNES INSTITUTE

SCIENTIFIC OFFICER

required in the Department of Applied Genetics to work on problems associated with the micropropagation of potato. This will involve the use of tissue culture techniques. The appointment is for three years and is funded by the Potato Marketing Board.

Applicants should hold an Honours degree in botany, agriculture or a related field. Salary £3,289 to £5,085. Starting salary depending on qualifications and experience. Non-contributory superannuation.

Applications, quoting reference AG/44 giving details of qualifications and experience and the names of two referees should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich, NR4 7UH, not later than 20th August, 1979. 2674(A)

ROBERTSON RESEARCH INTERNATIONAL LIMITED

SEDIMENTARY GEOLOGIST

Robertson Research International Limited has a vacancy in their head office in North Wales for a sedimentary geologist. Applicants should have a PhD in geology and be familiar with the full range of sedimentological techniques relevant to carbonates and/or clastics. The position is challenging with career prospects, and will require the successful candidate to work both on individual assignments or in a team of geologists. Work is concerned with the study and intepretation of rocks from oil prospective areas. Preparation of technical reports is an integral part of the duties and experience in this field is required. Successful applicants must be willing to travel and work both within the British Isles and abroad. Salary is competitive and is negotiable depending on age, experience and qualifications, and the position is permanent and pensionable.

For application forms please apply to:

Janet Hedges, Robertson Research International Limited, 'Ty'n-y-Coed', Llanrhos, Llandudno, Gwynedd LL30 1SA, North Wales. 2657(A)

BIOCHEMICAL VIROLOGY

A junior or senior postdoctoral position is available to study biochemical aspects of influenza virus replication and antigenic variation in influenza viruses. Successful candidates must have strong backgrounds in biochemistry. Send curriculum vitae and a statement of career goals to Dr R G Webster, Division of Virology, St Jude Children's Research Hospital, P O Box 318, Memphis, Tn. 38101. An Equal Opportunity/Affirmative Action Employer. W236(A)

The CAMPDEN FOOD PRESERVATION RESEARCH ASSOCIATION

Chipping Campden, Glos., GL55 6LD., requires a

FOOD SCIENTIST, FOOD TECHNOLOGIST, or HOME ECONOMIST

to head the quality appraisal team in its Department of Agriculture and Quality. The successful candidate will be enthusiastic, have qualities of leadership and get on well with people. Salary in the Research Officer grade £3,048 to £5,316.

Futher details and application form from the Secretary-General at the above address. 2675(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL

DEPARTMENT OF HISTOPATHOLOGY

GRADUATE NEUROSCIENTIST

required to take part in research programme on effects of alcohol on brain development. Biochemical and/or morphological expertise desirable.

Appointment will be for three years, funded by a research grant from the Medical Research Council. Salary up to £4,914, dependent on qualifications and experience.

Application forms and further particulars may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 6/205/N. 2678(A)

NATIONAL UNIVERSITY OF LESOTHO

Applications are invited for the

CHAIR OF BIOLOGY

tenable from January 1980. Applicants must have a PhD or Masters degree in Biology. They are expected to have documented research ability as well as teaching experience. Lesotho offers considerable scope for research in ecology, palaeontology, and agricultural botany/zoology and applicants with these specialisms would be particularly welcome. Salary scale: R8,580 to 9,000 pa (£1 sterling = R1.86). The British Government may supplement salary by £3,870 pa (sterling) for married appointee or £2,766 pa (sterling) for single appointee (reviewed annually and normally free from tax) and provide childrens education allowances and holiday visit passages. Family passages; baggage allowance; superannuation for those on contract terms is 25% gratuity for the first 2 years rising to 27½% and 30% for each subsequent period of service; 15% inducement for those not in receipt of supplementation unless married to another supplemented member of staff; education allowance; study leave; overseas leave.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Assistant Registrar (Appointments) NUL, Roma, Lesotho by 27 August 1979. Applicants resident in the UK should also send one copy to Inter University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 2698(A)

UNIVERSITY OF ABERDEEN

SENIOR LECTURESHIP IN ANATOMY

Applications are invited for the above newly created post. Candidates should have a strong background in morphological science, and ability to teach both gross and microscopic anatomy is essential. No field of research interest is excluded, but applications from those interested in microscopy, cell biology, neurobiology or endocrinology will be especially welcome. While candidates with a medical qualification would be preferred, non-medical applicants are by no means excluded.

Salary on scale £8,698 to £10,775 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 18 August 1979. 2658(A)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL

(University of London)

POST-DOCTORAL RESEARCH FELLOW IN ELECTROPHYSIOLOGY

required to investigate the actions of peptides on cells of the peripheral nervous system in collaboration with Dr T.B. Bolton on an MRC project. Salary in the usual scale (University 1A).

Appointment for 3 years from October 1979 or soon as possible thereafter. Applicants should be committed Electrophysiologists, preferably not more than 28 years old, with experience of intracellular recording techniques. Curriculum vitae, with names of 2 referees, to Dr Bolton (from whom further details can be obtained — 01 672 1255 Ext. 4722), Pharmacology Department, St. George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE. Closing date 31st August. 2717(A)

---

university college of swansea

Technicians

Applications are invited for the following vacancies of Technician in the Department of Zoology.

Trainee Technician: Applicants should be under 21 years of age and have four GCE 'O' level passes or Grade 1 CSE, including mathematics and a science subject. The successful candidate will work in an instrument laboratory and/or teaching laboratories.

Technician Grade 3: Applicants should be over 21 years of age and have an ONC or equivalent. The successful candidate will work in an instrument laboratory and/or teaching laboratories.

Technician Grade 5: The successful candidate will be required to give training in histological techniques for light and/or electron-microscopy.

The salaries will be as follows:

Trainee Technician: up to £2,397 per annum

Technician Grade 3: £2,931 to £3,336 per annum

Technician Grade 5: £3,474 to £4,056 per annum

Application forms may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by *Tuesday, 7 August, 1979.* 2689(A)

UNIVERSITY COLLEGE LONDON

Applications are invited for the post of

RESEARCH ASSISTANT

from recent graduates in Biochemistry. Starting date after August 1 by mutual agreement. Salary in range £4,219 to £5,307 inclusive of London Allowance, according to age and experience. The project, under the direction of Professor B. R. Rabin, is concerned with the biosynthesis of membrane proteins and is supported by the Cancer Research Campaign.

Applications including full curriculum vitae and names of two academic referees should be sent as soon as possible to Professor Rabin, Dept of Biochemistry, University College London, Gower Street, London WC1E 6BT. 2703(A)

CHARING CROSS HOSPITAL MEDICAL SCHOOL

(University of London)

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a post of temporary Research Assistant. Duties attached to the post include assistance in the chemical synthesis of heterocyclic compounds and in the study of their metabolism. Interest in experimental work and some experience in organic chemical synthesis are the prime requirements. Subject to a probationary period the appointment will be for two years at a salary of £3,000 per annum. Enquiries to Mr W O Sykes, telephone 01-748 2040, ext. 2610.

A vacancy also exists for a Technician or Junior Technician to assist with the technical work of the Department. Salary on scale £3,261 to £4,680 (Technician) or within range £1,905 to £3,015 (Junior Technician according to age and experience). A London Weighting Allowance of £354 is payable in addition and the salary scales are currently under review. Further information from Mr D J Strutt, telephone 01-748 2040, ext. 2043.

Applications for both appointments to be submitted on forms obtainable from the Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St Dunstan's Road, London W6 8RP, by 3rd September. (Ref: 032/3). 2696(A)

SCIENTIFIC OFFICER

BLOOD GROUP REFERENCE LABORATORY

A graduate is sought for research and development of new techniques relating to the standardisation of reagents (including albumin and enzymes) used in blood group serology. Some experience in protein chemistry or immunochemistry desirable.

Applications in writing with details of experience and the names of two referees to Miss K. Lomas, Blood Group Reference Laboratory, Gatliff Road, off Ebury Bridge Road, London SW1W 8QJ 2714(A)

THE OPEN UNIVERSITY

Earth Sciences Department

Technician £3,474-£4,056

A vacancy exists in the new Mass Spectrometry Laboratory for a Technician. The successful applicant will be responsible for the day to day running of the ultra-clean laboratory area. Duties will include distillation and calibration of ultra-clean reagents, preparation of samples for the solid-source mass spectrometer, and stock control of chemicals and laboratory equipment. There will be considerable opportunity to work closely with academic staff in the development of new techniques and their implementation in a wide variety of projects in the geological sciences.

Applicants should possess a degree in Chemistry with at least four years relevant experience.

Application forms and further particulars are available from The Recruitment Office, (JD3790/1), The Open University, PO Box 75, Walton Hall, Milton Keynes, MK7 6AL or telephone Milton Keynes 63404: there is a 24 hour answering service on 63868.

Closing date for applications is 10th August. 2679(A)

OXFORD UNIVERSITY
PHYSICAL CHEMISTRY LABORATORY

APPOINTMENT OF POST DOCTORAL RESEARCH ASSISTANT

Applications are invited from chemists or physicists to work on the development of lasers for isotope separation. Applicants should have some experience of working with lasers.

The appointment is for 2 years in Research support grade 1A with membership of U.S.S. Starting salary is up to £4,776.

Applications with curriculum vitae and the names of two referees should be sent as soon as possible to the Administrator, Physical Chemistry Laboratory, South Parks Road, Oxford OX1 3QZ. 2676(A)

UNIVERSITY OF DURHAM
DEPARTMENT OF ZOOLOGY

POST-DOCTORAL RESEARCH ASSISTANT

required from 1st October 1979, for a three-year project on control of lipogenesis and membrane biogenesis during hormone-induced cell differentiation in avian liver. Research experience in biochemistry or a related field is essential and experience of cell culture/immunochemistry would be an advantage.

Initial salary in the range £4,333 to £4,910 per annum within range 1A, plus superannuation.

Applications (3 copies) including curriculum vitae and naming three referees should be sent by 10 August 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham, DH1 3LE, from whom further particulars may be obtained. 2655(A)

Postdoctoral position open for

YOUNG ELECTRON MICROSCOPIST

interested in supramolecular, biological structures and who is prepared to use various specimen preparation techniques, for which instruction is provided. Some proficiency in electron microscopy in any biological field is required. Well equipped laboratory (including STEM); will work in close collaboration on many biological research projects.

Send curriculum vitae and names of three references to:
Prof. Edward Kellenberger, Department of Microbiology, Biozentrum, University of Basel, Klingelbergstrasse 70, 4056 Basel, Switzerland. W255(A)

BIOCHEMIST
Topic: Parathormone dependent calcium influence on lymphocyte functions

Application from suitable qualified candidates are invited for a research fellowship. Considerable experience in hormone-receptor interactions, ion transport and cellular biology is required. All modern technical equipment is available. Payment BAT II a. The appointment will be made for 3 years. Applications with curriculum vitae, recent publications and the names of two referees should be sent to:

H. Meyer zu Schwabedissen, Calcium Metabolism Research Group, Inst. Dr R.D. Hesch, Dept Endocrinology, Medizinische Hochschule Hannover, Karl-Wiechert Allee 9, Germany. W256(A)

MEDICAL RESEARCH COUNCIL
LABORATORY OF MOLECULAR BIOLOGY

RESEARCH ASSISTANT

required to take part in studies on the biochemistry of transcriptional regulation in prokaryotes and eukaryotes.

Qualifications: Degree or Higher National Certificate or equivalent. Salary: Scales under review. Present starting salary for candidates just qualified £3,261 pa, rising by annual increments to maximum of £4,902 pa. Prospects of promotion to higher grade.

Please apply to Miss F M Taylor, MRC Laboratory of Molecular Biology, The Medical School, Hills Road, Cambridge CB2 2QH. 2693(A)

MRC MAMMALIAN GENOME UNIT

The Medical Research Council invite applications for the post of

DIRECTOR

of their Mammalian Genome Unit, which is housed in the University of Edinburgh.

Candidates should be persons of high scientific standing and proven ability to lead a research team. The salary will be within the range for the Council's Special Appointments Grade, which is equivalent to the Universities' professorial range.

Further particulars may be obtained from Dr K I Gibson, Medical Research Council, 20 Park Crescent, London W1N 4AL to whom applications should be addressed. The final date for receipt of applications is 7 September, 1979. 2707(A)

INSTITUTE OF CANCER RESEARCH: DIVISION OF CHEMISTRY: A POST-DOCTORAL ORGANIC CHEMIST will be required from October 1st to work as a member of a multi-disciplinary project group concerned with the development and application of new reagents for the detection of steroid hormone receptors in human tumours. The post, for three years, will be funded by the MRC and the work will be carried out in the Institute's Haddow Laboratories in Sutton, Surrey. Starting salary will be in scale £4,261 to £4,805 p.a. (MRC non-clinical scientist Grade II) plus London Allowance of £502 p.a. Applications with CV and details of research experience (in duplicate) and with the names of two referees should be sent to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 300/G/11. 2710(A)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF PURE MATHEMATICS

TEMPORARY LECTURESHIP

Qualified Mathematicians are invited to apply for the above post, which will involve normal lecturing duties in the department. The appointment will run from 1 October 1979 to 30 September 1980.

Salary will be on the scale £4,333 to £8,992 (to operate from 1.10.79) plus superannuation.

Starting salary will depend on age, experience and qualifications.

Applications (three copies) including curriculum vitae and the names of three referees should be sent by 17th August 1979 to the Assistant Registrar, Science and Engineering, University of Birmingham, PO Box 363, Birmingham B15 2TT, from whom further particulars can be obtained. Please quote ref: NA1. 2684(A)

UNIVERSITY OF BRISTOL
SCHOOL OF CHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistant to join a group investigating the metabolism of gibberellins in higher plants. Some experience in the synthesis of isotopically-labelled compounds would be advantageous.

The appointment, funded by the SRC, is for a maximum of two years. Salary in the range £4,232 to £4,776 p.a. (scale subject to revision from 1st October, 1979).

Applications, enclosing a curriculum vitae and the names of two referees should be sent to Professor J. MacMillan by 31st August, 1979. 2650(A)

INSTITUTE OF CANCER RESEARCH: DIVISION OF CHEMISTRY: A JUNIOR TECHNICIAN is required to work in the Institute's Haddow Laboratories in Sutton, Surrey as part of a research team investigating steroid hormone receptors in human tumours. Applicants should have two 'A' levels in Maths, Physics or Chemistry. Starting salary will be £2,169 p.a. (under review) plus London Allowance of £354 p.a. Applications in duplicate with the names of two referees should be sent to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 301/B/82. 2709(A)

FELLOWSHIPS

FELLOWSHIP AT THE FRIEDRICH MIESCHER-INSTITUT, Basel, Switzerland

In the Friedrich Miescher-Institut, a fellowship (2-3 years) is available for a PhD or MD in a research group examining the role of endogenous C-type viruses in leukemogenesis and lymphocyte function. Salary in accordance with the Swiss National Foundation. Travel costs will be covered.

Candidates, preferably with experience in immunology, virology or nucleic acid chemistry, please write to:
Dr Christoph Moroni, Friedrich Miescher-Institut, P.O. Box 273, CH-4002 Basel, Switzerland. W253(E)

THE CITY UNIVERSITY
DEPARTMENT OF PHYSICS

POST-DOCTORAL FELLOWSHIP IN GEOPHYSICS

A post-doctoral fellowship financed by the Natural Environment Research Council is available for a study of the inter-action of elastic-waves with sub-surface features in solid media. (With special reference to shallow seismic surveys.)

The programme involves numerical modelling together with experimental verification on both laboratory and field scales. A geophysicist, physicist, engineer or applied mathematician would be eligible, the primary qualification being an interest in computer modelling. The appointment will be for 2 years and the commencing salary is expected to be £5,007 including London Weighting with superannuation U.S.S.

Further information can be obtained from Professor A F Brown, Department of Physics, The City University, Northampton Square, London ECIV 0HB, tel. 01 253 4399 ext. 391 or 215. 2720(E)

UNIVERSITY OF DUBLIN
Trinity College

POST-DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a post-doctoral research fellowship supported by the National Board for Science and Technology to study the structural control of mineralisation across central Ireland, using detailed structural methods and remote sensing. The project will involve three years of collaborative research with a small group of structural geologists and computer scientists.

Salary scale: £4,173 to £4,516, plus field expenses.

Further details can be obtained from Dr W.E.A. Phillips, Department of Geology, Trinity College, Dublin 2, telephone (01) 772941, Ext. 1074, Telex No. 5442 TCD EI, to whom applications with curriculum vitae and the names of two referees should be addressed.

Closing date for receipt of applications will be August 31st 1979. 2718(E)

UNIVERSITY OF WARWICK
RESEARCH FELLOWSHIPS IN MICROBIOLOGY

Several postdoctoral positions are available in the Microbiology group in the Department of Biological Sciences, to work on the biochemistry and physiology of methane-oxidizing bacteria with Dr H. Dalton and the control and regulation of cellular differentiation in prokaryotic model systems with Dr C.S. Dow. Candidates with interests in either of these topics should contact the above named lecturers from whom further details may be obtained.

The appointments will be for three years in the salary range £4,333 to £5,488 p.a. Application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref.No:51/A/79 2711(E)

QUEEN MARY COLLEGE (University of London)
ZOOLOGY AND COMPARATIVE PHYSIOLOGY DEPARTMENT

Applications are invited for a Postdoctoral

RESEARCH FELLOWSHIP

to work with Dr L.J. Goodman on sensory mechanisms controlling orientation during locomotion, including flight, in the honeybee. Applicants should be experienced in electrophysiological recording techniques and preferably familiar with intracellular recording and staining methods. Appointment for 3 years from 1 October.

Initial salary in range (under review) £4,835 to £5,412 p.a. (including London Allowance). Please apply as soon as possible, giving age, qualifications, experience and names of 2 referees, to The Registrar, (N) Queen Mary College, Mile End Road, London E1 4NS. 2687(E)

INSTITUTE OF CANCER RESEARCH
A three year post-doctoral Fellowship is offered for a Protein Chemist in the Division of Molecular Biology to work on the isolation and characterisation of chromosomal proteins. Experience of protein sequencing techniques would be an advantage. Salary in range £4,261 to £4,805 per annum plus London Allowance of £502 per annum.

Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place London SW7 3NU, quoting ref 300/G/10 2654(E)

FELLOWSHIPS and STUDENTSHIPS continued

EMBO

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY AUTUMN 1979 AWARDS

Next deadline: August 31, 1979

EMBO long term fellowships are initially awarded for one year. Applications for a renewal for a second year and subsequently **in cases of exceptional scientific merit for a third year** are considered.

To be eligible a candidate must hold a doctors degree. Preference will be given to European and Israeli applicants wishing to work within Europe or Israel. EMBO long term fellowships are not, however, awarded for exchanges between laboratories within any one country. Applications for fellowships to be held outside Europe and Israel are considered but they have a lower priority, as do applications from non-European scientists wishing to work in Europe or Israel.

Successful applicants will be notified of their awards on October 29, 1979.

Further details and application forms may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F. R. Germany.

W251(E)

MAX-PLANCK-INSTITUT FÜR MOLEKULARE GENETIK, BERLIN

offers

RESEARCH FELLOWSHIP

and seeks

BIOCHEMICAL TECHNICIAN

A postdoctoral research fellowship is available for the study of function, structure and assembly of ribosomes. Experience in either electron microscopy (negative staining and shadowing of biomolecules), or immunochemistry, protein chemistry, or in the field of protein synthesis, while not essential, would be an advantage. The fellowship is available immediately for up to 2½ years with probable extension (DM40,000 to 50,000 pa). Applications should include a curriculum vitae, a list of publications, and the names of at least three referees.

Applications are invited from **Technicians/Research Officers** for work involving electron microscopy and/or immunochemistry. Applicants should have at least two years relevant laboratory experience and should be able to work on research projects without day-to-day supervision. (Position available immediately, for up to three years; salary scale depending on experience and age: DM25,000 to 30,000.)

All applications should be sent to Professor Georg Stöffler, Max-Planck-Institut für Molekulare Genetik, Ihnestrasse 63/73, D1000-Berlin 33. W257(E)

UNIVERSITY COLLEGE, DUBLIN and DUBLIN INSTITUTE for ADVANCED STUDIES

POST-DOCTORAL FELLOWSHIPS in MATHEMATICAL PHYSICS

pplications are invited for two positions upported by the National Board for cience and Technology to work on wave ropagation in elastic materials with plictions to seismological problems. The ellowships are available from 1st October 79, for one year initially with extensions ssible for a further two years, at a salary the range £3,837 to £3,994. to £4,153 to ,311. to £4,476. (at present under view).

Intending applicants should, without lay, contact either Professor Michael ayes, Department of Mathematical aysics, University College, Dublin, 4, elephone 693244, or Professor John ewis, School of Theoretical Physics, ublin Institute for Advanced Studies. 10 rlington Road, Dublin, 4, Telephone 0748. 2716(E)

Southampton THE UNIVERSITY

SOLAR CELL THEORY
Post-doctoral SRC Fellowship

Applications are invited for the above post-doctoral post which is available from 1 September 1979, and is suitable for appropriately interested mathematicians, physicists or engineers. Salary up to £4,505.

Applications giving the names of two referees should be sent to Professor P T Landsberg, Department of Mathematics, University of Southampton, Highfield, Southampton SO9 5NH, before 9 August 1979. Please quote Ref: N. 2662(E)

QUEEN MARY COLLEGE (University of London)

LASER MEASUREMENT OF BOVINE SPERMATOZOA MOTILITY

Applications are invited for a 2-year Postdoctoral

RESEARCH FELLOWSHIP,

from 1 October, to work with Dr D.A. Ross, in conjunction with the Ministry of Agriculture Cattle Breeding Centre, Reading, to verify the viability of routine assessment of samples of frozen semen, using the new fibre optic Doppler anemometer, and to correlate motility measurements with fertility trials. Candidates with a PhD in Physics or Electrical Engineering and interest in or direct experience with laser anemometry or photon correlation preferred. Initial salary in range (under review) £4,835 to £5,412 p.a. (including London Allowance). Please apply by 15 August, giving age, qualifications, experience and names of 2 referees, to The Registrar, (N), Queen Mary College, Mile End Road, London E1 4NS. 2688(E)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF BOTANY

SRC/CASE RESEARCH STUDENTSHIP WITH ENGLISH CHINA CLAYS LTD

(Amelioration of Derelict Land Materials for Vegetation establishment)

This work will examine the effects of organic and inorganic amendment to raw china clay waste, to improve situations for land reclamation. It should provide interesting work for someone with practical and theoretical interests.

Applications with the names of two referees should be received not later than 9th August, 1979, by The Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/706/N. 2660(F)

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

ARC POST-DOCTORAL RESEARCH FELLOWSHIP IN CHLOROPLAST BIOCHEMISTRY

Applications are invited for a post-doctoral Research Fellowship to investigate the characteristics and control of chloroplast division in wheat leaves under the direction of Professor Rachel Leech. The project will involve the study of the role of the nuclear genome in the regulation of chloroplast division. Preference will be given to applicants with experience in both plant biochemistry and plant ultrastructure.

The appointment, which will be on Grade 1A of the national salary scales for research staff, will be for three years.

Informal enquiries and further particulars from Professor R. M. Leech, Department of Biology. Two copies of applications, giving a curriculum vitae and the names of two referees, should be sent by Friday 1 September 1979 to the Registrar, University of York, Heslington, York, YO1 5DD. Please quote reference number 11/6105(a). 2653(E)

PHYSICAL BIOCHEMISTRY

Applications are invited for a post-doctoral research fellowship to work on the spectroscopy and kinetics of ribosomal systems in the Max-Planck-Institut für Molekulare Genetik in West Berlin.

Candidates are expected to have a PhD in chemistry or physical biochemistry and some experience of spectroscopy. Research experience in biochemistry and some knowledge of German would be helpful but not essential.

Applications (which must include a full academic curriculum vitae and a short statement of research experience) should be sent to Dr P. Woolley, Max-Planck-Institut für Molekulare Genetik, Ihnestrasse 63-73, 1000 Berlin 33, W. Germany. W254(E)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF CANCER STUDIES

PhD STUDENTSHIP

A good honours degree graduate (Microbiology, Biological Science, or Virology) is required to join a project which has a three year Cancer Research Campaign grant to study the interaction of human wart viruses with human epithelial cells in tissue culture.

Applications giving a full curriculum vitae and the names of two academic referees should be sent to Dr P H Gallimore, Department of Cancer Studies, University of Birmingham. 2695(F)

STUDENTSHIPS

UNIVERSITY OF BRITISH COLUMBIA Vancouver, Canada

DEPARTMENT OF PHYSIOLOGY

Applications are invited for a research studentship available from September 1st, 1979. The successful candidate will be expected to work in the field of the reflex control of the cardiovascular and respiratory systems and to register for a higher degree. Applicants should have a First Class or Upper Second Class Honours degree in a biomedical subject.

The studentship will be valued at $6,500 per annum and may be supplemented by additional teaching duties.

Applications including a curriculum vitae and the names of two referees should be sent as soon as possible to Dr J R Ledsome, Department of Physiology, UBC, Vancouver, BC, Canada V6T 1W5. W243(F)

FOR SALE and WANTED

ALMOST ANY SCIENTIFIC and learned periodicals, proceedings, transactions etc. wanted in long and complete runs/sets. H. Pordes Ltd., 529B Finchley Road, NW3 7BH. Tel: 01-435 9878 after 2 p.m. 2673(L)

ASSISTANTSHIPS

UNIVERSITY COLLEGE LONDON
CHEMISTRY DEPARTMENT
POST-DOCTORAL RESEARCH ASSISTANTSHIPS

Applications are invited for SRC post-doctoral research assistantships in the following fields:
Dr A J Bloodworth: A new approach to the synthesis of crown ethers and related macroheterocycles.
Dr T M Cresp: The total synthesis of some biologically active sesquiterpenes.
Professor A G Davies: Homolytic reactions of organic and organometallic compounds, and the study of the radical intermediates by e.s.r. spectroscopy.
Dr M D Johnson: Rearrangements of organic ligands in organotransition metal compounds.
Dr B P Roberts: E.s.r. studies of transient organic and organometallic radicals and radical ions, generated by electrochemical, photochemical, and non-acqueous flow techniques; some organic synthesis will also be involved.

Appointments will be for one year in the first instance, with the possibility of renewal, and the salary will be within the range £4,763 to £5,576 plus USS.

Applications, with a curriculum vitae and names and addresses of two referees, should be sent as soon as possible to the appropriate staff member at the Chemistry Department, University College London, 20 Gordon St, London WC1H 0AJ, UK. (Tel: 01-387 7050) 2702(P)

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF CHEMISTRY

Applications are invited from men and women for an
S.R.C. POSTDOCTORAL RESEARCH ASSISTANTSHIP
to study the photochemistry of carbanions and, in particular the cis-trans photo-isomerisation of diphenyl-allyl and related anions. Experience of vacuum techniques for handling reactive compounds and/or photo-chemistry or photophysics (flash photolysis, measurement of fluorescence lifetimes and spectra) needed.

Tenable three years from 1 October 1979. Initial salary up to £4,910 a year on Range IA.

Applications, naming two referees to Drs B. Brocklehurst and R.N. Young, Chemistry Department, the University, Sheffield S3 7HF, from whom further information can be obtained. Quote ref: R 343/G. 2680(P)

UNIVERSITY OF MANCHESTER
DEPARTMENT OF MEDICAL BIOPHYSICS
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a post-doctoral research assistantship, tenable for one year in the first instance, to study molecular organization in collagen fibrils. Experience in electron microscopy and in computing essential.

Applications, with names of two referees, should be sent immediately to Dr J.A. Chapman, Dept. of Medical Biophysics, Medical School, Oxford Road, Manchester, M13 9PT, from whom further particulars can be obtained. Please mark envelopes "PDRA application". 2713(P)

UNIVERSITY OF OXFORD
LABORATORY OF MOLECULAR BIOPHYSICS
POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for an SRC post-doctoral research assistantship to carry out research on the refinement of the crystal structure of glycogen phosphorylase b at 2A resolution. The refinement is a challenging problem and should lead to a detailed understanding of the conformation, control and catalytic properties of this key control enzyme. An ICL 2980 computer in the University of Oxford and a Cray 1 backed by an IBM 360/165 at the SRC Computing Laboratory at Daresbury are available for this work. Applicants should have experience in crystallographic computing. The position is for 3 years with salary according to age and experience in the range Grade 1A (£5,048 at age 27). Applications with the names of two referees should be sent by September 1st to Laboratory of Molecular Biophysics, South Parks Road, Oxford OX1 3PS. 2721(P)

UNIVERSITY OF LONDON
ST BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE
and the
INSTITUTE OF NEUROLOGY

Applications are invited from good honours graduates in Biochemistry or related subjects for a
RESEARCH ASSISTANTSHIP
to undertake investigations into the metabolism of muscle mitochondria in both normal and diseased states. The successful candidate would be expected to register for a PhD degree.

The appointment is for three years from 1st October at an initial salary (under review) of £4,191 per annum including London weighting.

Applications, with c.v. and names of three referees, should be sent by 20th August to Dr J B Clark, Biochemistry Department, St Bartholomew's Hospital Medical College, Charterhouse Square, London EC1M 6BQ (Tel: 01-253 0661, ext 22). 2628(P)

UNIVERSITY OF EAST ANGLIA
Norwich

Applications are invited for one
SRC GRADUATE RESEARCH ASSISTANTSHIP
in the School of Chemical Sciences (salary 1B scale) to work on the magnetic circular dichroism spectra of metalloproteins and their inorganic models. The post will involve liaison with groups of biochemists at various Universities and is suitable either for a chemist or a biochemist with physio-chemical interests. The award is tenable for three years. If appropriately qualified the successful candidate will be permitted to register for the degree of PhD. Candidates should have or expect to obtain soon a good honours degree. Application, including the names of two referees, as soon as possible, to Dr A. J. Thomson, School of Chemical Sciences, University of East Anglia, Norwich NR4 7TJ, from whom further details may be obtained. Salary from £3,689 rising by increments of £271. 2652(P)

ST PATRICK'S COLLEGE
Maynooth, Co Kildare
Ireland
DEPARTMENTS OF BIOLOGY AND CHEMISTRY

Applications are invited for a post-doctoral research assistantship supported by the NBST to study fundamental biological and chemical aspects of the ensilage process, in association with An Foras Talúntais (The Agricultural Institute). The project involves the development of a novel model silo in which the fundamental biochemistry, chemistry and microbiology of the process of silage making will be studied in an interactive manner. (Salary scale: £4,173 to £4,516, under review.)

Further details can be obtained from either Professor C M Quinn, Department of Chemistry, or Professor P A Whittaker, Department of Biology, St Patrick's College, Maynooth, telephone (01) 286262, telex 31493, to whom applications with curriculum vitae and the names of two referees should be addressed. 2690(P)

COURSES

BIRBECK COLLEGE (University of London)
DEPARTMENT OF ZOOLOGY
M.Sc. IN ENTOMOLOGY

This two-year, part-time evening course is designed primarily for entomologists but also allows teachers and others to extend their training in a scientific discipline and to become conversant with the tools of current research. Topics covered include: sensory and neuromuscular physiology, respiratory physiology, osmotic and ionic regulation, insect genetics, taxonomy and economic entomology.

For further details contact the Departmental Secretary, Department of Zoology, Birkbeck College, Malet Street, London, WC1E 7HX. 2683(D)

UNIVERSITY OF LEICESTER
DEPARTMENT OF ASTRONOMY
SRC RESEARCH ASSISTANTSHIP IN THEORETICAL ASTROPHYSICS

Applications are invited for a research assistantship for three years from 1 October 1979. Salary scales at present are £4,232 to £5,850 with agreed scales at £4,333 to £6,066 and subject to further review expected to be effective from 1 October 1979.

The current theoretical research interests of the Department are in the areas of (a) cataclysmic variables and (b) active galaxies which are carried on in collaboration with the X-ray and infrared astronomy groups. For further details and application form write to The Secretary, Department of Astronomy, The University, Leicester LE1 7RH. The closing date for applications is 20 July 1979. 2712(P)

BIRBECK COLLEGE (University of London)
DEPARTMENT OF ZOOLOGY
M.Sc IN COMPARATIVE PHYSIOLOGY

A two-year part-time evening course suitable for zoology graduates wishing to specialise in the comparative aspects of the adaptations of animals to their environment. Topics covered include: osmotic and ionic regulation; respiratory & circulatory physiology; endocrinology; neurophysiology. Students are introduced to a wide range of modern physiological techniques.

For further details contact the Departmental Secretary, (N) Department of Zoology, Birkbeck College, Malet Street, London, WC1E 7HX. 2682(D)

ASSOCIATESHIPS

HERIOT-WATT UNIVERSITY
DEPARTMENT OF CHEMISTRY
RESEARCH ASSOCIATES

Applications are invited for one SRC Postgraduate and two SRC Postdoctoral Research Associateships to commence on 1 October 1979.

(a) Quantitative Studies in Silaethylene Chemistry
The successful applicant will collaborate with Dr. P. John and Professor B. G. Gowenlock.
A physical chemist is required with experience in gas phase kinetics to continue studies of reactive intermediates in silicon chemistry.

(b) Reactions of Elemental Phosphorus with Transition Metal Complexes
The appointed person will work in conjunction with Dr. W. E. Lindsell. Previous experience in synthetic organometallic/inorganic chemistry would be advantageous.

(c) Oxygen Complexes of Organo-Transition Metal Derivatives
This interdisciplinary project would suit applicants with expertise in synthetic organic or organometallic chemistry and/or solution spectroscopic techniques.
The successful applicant will work with Dr. W. E. Lindsell and Dr. P. N. Preston.

Informal enquiries regarding the individual projects would be welcomed. Phone (031 449 5111) or write to the persons below for further details.

Each appointment will be available for a period of two years. Starting salary for post (a) will be £3,775. Starting salary for posts (b) and (c) will be £4,333.

Superannuation under the USS scheme is available.

Applications, including a curriculum vitae and the names of two academic referees, should be sent to: post (a) Dr. P. John; posts (b) and (c) Dr. W. E. Lindsell, Department of Chemistry, Riccarton, Currie, Edinburgh EH14 4AS. 2656(O)

As easy as 1·2·5

If you've been wishing you could get rid of the inconvenience and difficulties of iodinating proteins, here is an easy way to do it. Get our simple, reliable Radioiodination System [^{125}I] – everything you need, ready for your protein.

We've selected a mild reaction method (enzymatic lactoperoxidase) to preserve your protein specificity. We've made sure that there are no contaminants to interfere with proper iodination. And we've tested each lot in a complete iodination procedure.

The ingredients are: Sodium iodide [^{125}I], iodination reagent, sterile protein-free buffer, 1% β-D glucose to activate the system, and a volatile radioiodine trap.

This system is the new way to make iodination straightforward and reliable. Send for the protocol to start saving time and trouble.

Not for use in humans or clinical diagnosis.

Happy Endings.

Your DNA research should have a happy ending. That's why Miles has developed enzymes that cleave and splice DNA easily and accurately.

All of our restriction nucleases–such as *Eco* RI–specifically cleave DNA within certain well-defined base sequences. And to make sure you're happy with the cleaved ends, we include a sample of lambda DNA for verification of enzyme activity... so you never risk your research DNA. The results of our stringent specification tests are reported on the chemical credential that accompanies each order. No surprises, no mystery.

And, for recombinant DNA, we have terminal transferase to add dA and dT segments and DNA ligase to splice fragments together.

Restriction nucleases, terminal transferase, DNA ligase. Miles enzymes for happy endings... and beginnings.

Please supply more information about:

☐ Restriction nucleases ☐ DNA ligase ☐ Terminal transferase

☐ Please send a current Miles Biochemical Catalog.

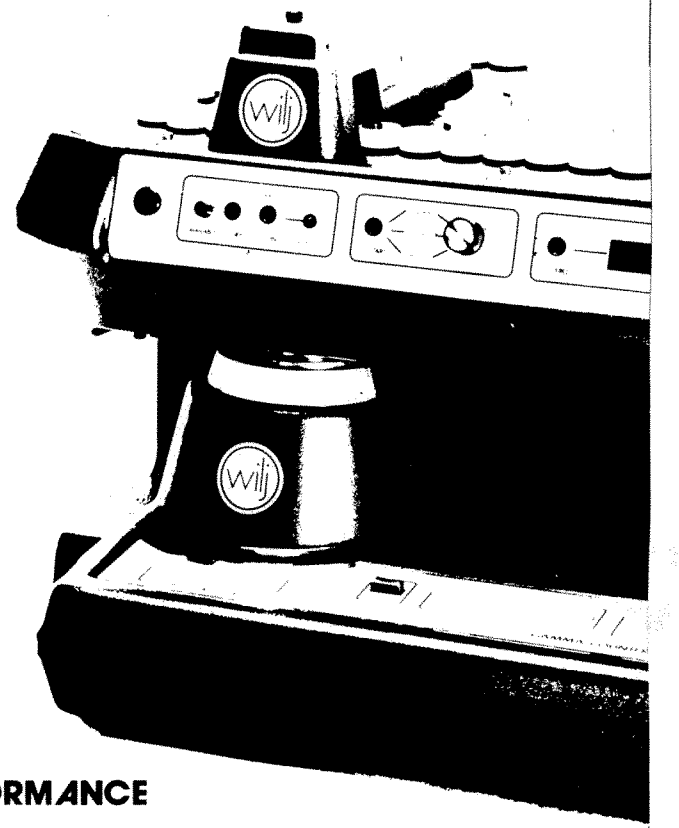
Disease and Population

The British family Wilj announce two talented new members

Gamma Counter 2001-S

* 50mm Crystal, 50mm shielding
* Multiple-channel facilities (SMIC)
* Additional user variable window
* Digital display directly in KeV
* Accepts alternative external counting heads
* Incorporates our unique easy to calibrate system



RIA Data-Processor 2701

* Easy to use — it asks you the questions
* Dual-channel
* Choice of curve fits: Polylinear, Logit/log & Spline
* Statistical checks

These two new additions increase Wilj's long lead on other lower-cost RIA equipment. This combination can count and process **double-isotope kits** in one simple operation.
Higher energy isotopes can be counted with the larger crystal and increased shielding.

Data-processing is no problem with Wilj peripheral options. Teletypes, paper tape, data-logger and the Hewlett-Packard 9815A programmable calculator and software can all be accommodated.

Whichever combination you choose, all Wilj products come complete with an unconditional 2 year guarantee. (U.K. Only)

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

Hunting the quangos

Britain's quangos should open themselves up more; putting them on the defensive will hardly help.

THE councils, committees, boards, institutes and so on, listed in the box, are all quangos. There exists no unique definition of a quango (originally a quasi-non-governmental organisation), but it may be taken that it performs governmental or public functions, or spends public money. It is not part of a government department, but it does have a dependent relationship with a department or with a minister for authority and/or for funds.

A quango-hunt is on at the moment; it is said that government ministers have been encouraged to see how many can be disbanded or trimmed. So it is valuable to have a report, *What's wrong with quangos?*, published by the Outer Circle Policy Unit (£2.00), which gives some background to the incredible diversity of quango that now exists. There are certainly serious questions to be asked of quangos — the report identifies issues of financial and political accountability, adequate provision of information concerning their activities and the secretive nature of much of the ministerial patronage that surrounds top appointments. In other words, quangos should be more open to scrutiny and accessible to the general public than they often are.

The question of who gets the plum jobs is a case in point. There is at present no provision whatsoever for most of the chairmanships of quangos to be advertised, nor (as the report points out) is there anything like adequate provision for an incompetent chairman to be brought to book. Furthermore many quangos have prestigious and influential councils where, again, the selection process is veiled from public view. And the council member's duties are most unlikely to contain any explicit instructions to consult or inform a particular constituency.

Many of the ministerial appointments to quangos draw from the very British concept of a pool of 'the good and the great' — a list of worthy people said to reside in Civil Service Department filing cabinets (the list, that is, not the people). But this list is not comprised of those who at various times have responded to advertisements or who have expressed a wish to involve themselves in policy matters — indeed, anyone who did so would probably be regarded as too pushy for appointment to anything. Rather, it is the product of a grapevine, and so unlikely to contain an adequate representation of those with radical views, those whose profession keeps them remote from well-trodden paths, or those not yet forty.

Many (but not all) of the scientific quangos listed fulfil very necessary functions which would still have to be done (by civil servants?) if there were wholesale trimming, 'rationalisation' or cuts. To this extent they are probably fireproof. But quangos also have the merit of exposing outsiders to insiders and *vice versa*, and so should fulfil a vital role, in highly compartmentalised Britain, of providing at least a modicum of cross-fertilisation across the yawning chasms which exist between communities — academics, bureaucrats, industrialists, politicians. For this reason, there should be the greatest resistance to any move to replace quangos, particularly by civil service operations. However, there is still scope for quangos to improve their relationship with the outside world, both in terms of recruitment and in terms of the provision of adequate information on their mode of working. A wholesale quango-hunt will cause just the opposite to happen.

Universities accused of inefficient book-keeping

David Dickson reports on continued skirmishing between US politicians, administrators and scientists over use of research funds

Government auditors have accused Harvard University of claiming over $2 million in "inappropriate" costs charged to federal research projects carried out by the university's School of Public Health between 1975 and 1977. They further state that, on the basis of sample studies of cost transfers, "we cannot attest to the proprietary of about $15 million charged to federal grants" during this period, out of a total of $37.1 million audited.

These conclusions have emerged from an audit carried out by the Department of Health, Education and Welfare following allegations that the university was violating agreed procedures for claiming research costs from the federal government. The university has already announced its intention to challenge the draft audit, which has not yet been publicly released; but the incident has fuelled further skirmishing between politicians, administrators and scientists over how universities should account for their use of public research funds.

The politicians insist that, since the funds come from the public purse and their expenditure has been decided by Congress, then it should be demonstrated that they are spent in the way that Congress intended. But the universities claim that too much time spent accounting for the use of funds can hamper the research scientist and may ultimately undercut the value of the research itself.

Allegations about Harvard's misuse of funds were first made by Dr Phin Cohen, previously a research worker in the School of Public Health, in 1975. He repeated the allegations — and provided details of DHEW's draft audit — at a hearing held recently by the intergovernmental relations and human resources subcommittee of the House committee on government operations.

A particular focus of the hearing was a report just completed by the General Accounting Office claiming that many audits of university research expenditures were "not as effective as they could be". In some cases, inadequate university accounting systems meant federal auditors were unable to give an opinion on the allowability of costs charged to federal grants and contracts.

The GAO points out, for example, that of $1.2 billion in research grants and contracts audited by DHEW in 1977, over a third was not properly documented. In one university, $53.7 million of personal service costs, out of $111 million charged to federal grants and contracts over a three year period, could not be adequately supported, since they were based on budget estimates rather than actual certified costs.

The GAO was also critical of some of the DHEW's audit operations. Department officials, however, while accepting some weaknesses in auditing procedures, placed considerable blame on the universities which, they said, frequently failed to keep accounts in a form which meets federal standards. Mr Edward Stepnick, assistant inspector general for auditing at DHEW said compliance with auditing requirements was non-existent or inadequate at about 70% of the major colleges and universities audited.

Universities, in turn, continue to charge that the accounting requirements placed on them are often unreasonable and unrealistic. Their accounting is in fact, much better than they are being given credit for, according to Dr Max Binkley, vice-president for finance at Colorado State University. Publicity alleging scandal and malfeasance gave the public the wrong impression of issues which principally involved questions of accounting precision and documentation, he said. "A scientist is deeply engrossed in the pursuit of new knowledge in his or her field of specialisation, with the result that efforts towards precision in costing are disruptive and burdensome and constitute an impediment to the accomplishment of the ultimate objective."

All sides hope that the situation will be improved by the recent revision of Circular A-21, a document published by the Office of Management and Budget laying down guidelines for charging the direct and indirect costs of research. Considerable differences still remain over costing principles, — particularly the way that research workers should account for the time spent on various projects — "the toughest and longest standing problem revealed by our audits" according to Mr Stepnick.

Harvard: sitting tight and challenging the audit

Under existing accounting rules, scientists receiving federal grant money have to report regularly on the way they have spent the previous month or two weeks. Under the revised A-21, a university can opt for a monitored workload system, in which the distribution of time is agreed before the project begins. Changes in the agreed workload have to be reported, and "significant" changes entered in the accounts. Mr Bowman Cutter, director of the budget in OMB, said this was a reasonable compromise, reached after considerable negotiation, between the demands of accountability and the flexibility needed by universities to administer research in an effective way.

University representatives, however, disagreed. They had been pressing that only *significant* changes in workload need be reported. "Insignificant changes to workload occur daily, perhaps even hourly," Dr Brinkley said. "Having to note all minor variations in activity was virtually impossible." He told the subcommittee that OMB's decision meant most institutions would not now adopt the monitored workload system, but opt instead for the personnel activity reporting, with which neither the government nor the universities were satisfied. "The overzealous attempt by the government to refine the system has evidently brought its defeat", he said.

Dr Thomas A. Bartlett, president of the Association of American Universities, told the subcommittee that his association wanted a number of changes in federal accounting rules. These included adoption of a monitored workload system "as a fully acceptable means for documenting effort", and grouping related grants for the purposes of administration. On the first, he echoed Dr Binkley's complaints that restrictions demanded by OMB in the revised Circular A-21 will probably deter widespread use of the system.

Dr Cohen suggested some more radical changes. He first described to the subcommittee how concern at the way university administrators had controlled the use of his grant money had led him to report the matter to the National Institutes of Health; following an investigation, the university had agreed to repay $132,350. Dr Cohen suggested the "re-enfranchisement" of principal investigators, who would sign all time and effort reports, salary certifications and reports of expenditure, rather than delegating these functions to university officials. □

SRC tries apprenticeship scheme

DETAILED plans for two new experimental schemes aimed at improving the performance of graduates in industry are now being finalised by Britain's Science Research Council. The programmes, to be based on part-time studies, represent an unusual step by the normally academically-orientated SRC and indicate a strong feeling that British industry in general makes poor use of its scientific and engineering intake.

Although many of the UK's larger companies have adequate training schemes for developing the industrial potential of new graduates, many smaller firms make practically no arrangements for this. The two SRC projects aim to remedy the bias.

The first scheme, known as graduate initial education, will take the form of an apprenticeship package which will follow newly qualified students into industry. Through systems of tutorials, demonstrations and company-based projects over a two- or three-year period it will tailor their performance to the specific needs of their firms. A first experimental package, to cost about £100,000, is to be ready for student intake in October 1980.

The second programme will consist of technological topping-up education for graduates of about 10-year standing who require up-dated instruction on new industrial practices. This will include the many managers whose educations cover only transistor electronics and not modern microelectronics. The scheme will aim at familiarity with a basic working knowledge.

In both systems, universities will probably undertake instruction, and may even award degrees if it is thought the schemes would otherwise affect staff-student ratios. However, in the case of the technological top-up programme, it is possible that the Open University, with its experience of popular presentation, may be introduced to instruct industrialists who might be alienated by a dry academic approach.

At the moment, both schemes are still at a rudimentary stage of planning and although they have been given the full go-ahead by the central council of the SRC, approval still has to be given by the Department of Education and Science as part-time higher education is not at present considered to be part of the council's remit.

Fine-tuning for technology, page 352.

Robin McKie

Max Planck production venture fails

"WE will concentrate future activities on our original function, which is to commercialise research results of the Max Planck Institute by licensing only," according to a spokesman of Garching Instrumente, a 100% commercial subsidiary of Max Planck Gesellschaft. The young enterprise has run into considerable difficulties, and finally has been forced to close down activities connected with the development and production of highly sophisiticated instruments and pilot equipment — activities that accounted for nearly three-quarters of Garching Instrumente's turnover and employment.

MPG established Garching Instrumente in 1970 as a limited liability company whose aim was to commercialise technically useful research results of the Max Planck Institute in the industrial field. Stimulated by successful American ventures of a similar kind (from which the un-German name "Instrumente" was borrowed) Garching Instrumente was not only to deal with licensing (especially of Max Planck Institute patents), but also with the development, production and distribution of high technology hardware.

From its beginning, the new company raised considerable hopes and expectations, for it was considered to be the prototype of the young, small high technology venture needed in West Germany. The importance attached to it can be deduced from the remarkable efforts of the Federal Ministry of Research and Technology in the early 1970s to establish a risk financing corporation specifically to assist risky high technology ventures.

In the first years of operation, at least, Garching Instrumente seemed to fulfil the high expectations. Turnover increased to DM4 million with around 24 staff; among its clients were big companies like Siemens AG, as well as small enterprises, research institutes and universities. About 75% of the licence agreements were contracted with the instrument, electronics and pharmaceutical industries.

As time passed, however, it became increasingly obvious that research work on the one hand and manufacturing business on the other were very different, and that switching from one to the other is not easy. The activities of the manufacturing division of Garching Instrumente seemed to be less and less in line with the expectations of the Max Planck Gesellschaft, and there were rumours not only of management deficiencies but also of losses higher than could be tolerated even in a newly founded venture. Now, as a consequence, MPG has closed down all development and manufacturing activities, dismissed the management and reduced the staff to a mere handful. Activities are now restricted to licensing.

The new management looks optimistically to the future: "The actual turnover out of licence agreements already exceeds DM1 million. That brings us near the break-even point of our present activities."

Maurice Bazin reports from Brazil on the return of the exiles for the country's major scientific conference

Scientists protest at US tycoon's Amazonian project

OVER 5000 scientists and social scientists congregated in the Brazilian north-east town of Fortaleza in mid-July for the 31st meeting of the SBPC, the Brazilian Society for the Progress of Science. The meeting's central theme was 'Dilemmas of Scientific Production in Brazil', reflecting the participants' preoccupation with the ways in which General President Figueiredo's Brazil is helping — or hindering — science. The problem of external dependency also lurked in the background as an ever-present spectre.

"The developed countries control science and technology, but they charge for letting us use it. And they charge dearly . . . . It is enough to see the chronic deficit of the Brazilian balance of payments. Part of this deficit comes from paying royalties and patent rights; these are, in the last analysis, the price we pay for scientific and technological dependence" read an official note distributed by the general secretariat of the SBPC on the opening day. This point came up at a round-table on 'National Scientific Policy' which involved three representatives of agencies financing scientific research in Brazil. Physics Professor José Leite Lopes, visiting his country after ten years of exile, declared: "It is useless to discuss a science policy without discussing the forces which oppose its formulation. Shall we discuss scientific policy without discussing economic policies?" He then added that nothing could be done as long as the economic forces representing the interests of multinational companies determine technological and scientific production in Brazil.

The president of the SBPC reminded everyone that the Brazilian scientific community was never consulted in the past about national projects, and it became evident during the meeting that academics were ready to take advantge of the recently granted freedom of expression to criticise strongly the government's options. The relaxed atmosphere of the meeting (where mornings were left free to allow participants to enjoy the town's beaches) was interrupted, however, when local police arrested five student participants for distributing "subversive material"; a federal security agent declared later that "in addition, they all had taken drugs".

The hottest discussions centred on two huge ongoing projects: the Jari agro-industrial project in the Amazonian jungle and the nuclear agreement with West

0028-0836/79/310347-02$01.00

© Macmillan Journals Ltd 1979

Germany to build eight 1000 Megawatt nuclear plants in Brazil. Daniel Ludwig, an American citizen, owns a land area the size of Switzerland at the confluence of the river Jari and the Amazon. Investments in homogeneous forest plantation, a cellulose factory, cattle raising and rice growing on this site amount to $700 million, and will reach $1.5 billion in a few years when a paper factory is completed.

Banners reading "Amazonia is ours" were spread around an overflowing amphitheatre as Charles Briscoe, the American technician in charge of the Jari Project, explained that "Project Jari covers more than one million hectares in the State of Pará and the Federal Territory of Amapá . . . There are no boats loaded with gold or other riches leaving the country." But critics pointed out that all of Jari's activities are geared exclusively for export, and that the appropriateness of their technology is never considered. Agricultural production, for example, is fully industrilized: rice is sown by plane and tree planting and cutting are fully mechanized. Parts of Briscoe's presentation met with boos from the participants, several of whom denounced foreign control and the elimination of the indigenous Indian population.

West German nuclear deal heavily criticised

The government's nuclear programme was strongly criticised by Brazilian physicists on economic and political grounds; the technical and environmental arguments which dominate the nuclear debate in industrialised countries were not brought up. Professor Luis Pinguelli Rosa of the Federal University of Rio de Janeiro proposed a drastic revision of the contract with West Germany. He claimed that Brazil is in a position of strength: "Germany presently does not have other clients for its reactors. The only reason we did not succeed in imposing our conditions is because we owe $40 billion to the industrialised world, and that forces us to follow a policy which is perfect for our creditors but not for ourselves." He also indicated that an official report by the Ministry of Planning recognises that the cost of electrical energy produced by nuclear reactors is three times that from hydroelectric schemes.

A longer-term view was presented by Professor Mario Schemberg, who trained some of the best known Brazilian physicists before he was forcibly retired from the University of Sao Paulo by the military government in 1969. He made an appeal for "freeing ourselves from the useless weight of the nuclear agreement with Germany, and cancelling the pledges which the military dictatorship made without consulting the people." He proposed an energy programme for Brazil for the next fifty years which would emphasise research in solar energy and nuclear fusion. □

Where have all the flowers gone?

THE savage destruction of the Brazilian rain forests has been dictated, to a large extent, by economic pressures over which the country's government can exercise little control. Yet this rapidly dwindling heritage of exotic plants and animals kindled the imagination of early explorers and continues to contribute to our understanding of our natural environment. In Brazil today the cultural and economic influence of the West is very apparent, and so it is strange to find little native interest in natural history reflected on the shelves of the big bookshops of cities such as Rio de Janeiro, Brasilia and Belo Horizonte. Despite a good deal of enquiry the only books I could find dealing with Brazilian wildlife at all were translations of glossy foreign 'coffee table' volumes.

Long searches through the second-hand markets uncovered only four more: a series published in São Paulo in the 1950s dealing with insects, birds and mammals; and a magnificent translation of an illustrated French book on Amazonian primates, published at the turn of the century — whose value was, unfortunately, well appreciated by the dealer. The Brazilian flora suffer a similar neglect, even though, at certain times of the year, one would be well advised to take some sort of field guide along when visiting the local fruit and vegetable markets.

Being able to name and classify species of plant and animal is an essential cornerstone of biological science and education. Once these basic elements can be identified, and their interactions understood, one may begin to appreciate the fragility of eco-systems such as the tropical rain forest.

It is disturbing, therefore, to find that wouldbe medical students, when asked to give the names of all the animal species they knew, could list, on average, only half a dozen — invariably creatures of medical importance such as the mosquito, the cockroach and the 'barbeiro', the bug vector of Chagas disease. Although this survey carried out by Professor Angelo Machado of the Federal University of Minas Gerais, did not include questions on plant life, my own experiences suggested that here the situation is even worse. Indeed, one graduate biologist I spoke to was surprised to discover that natural selection occurs outside the animal kingdom!

Machado is a well respected morphologist and neuroanatomist, whose spare time pursuits include some most elegant studies on the ecology and taxonomy of neo-tropical dragonflies. His wide interests include conservation — he is a founder member of one of the few environmental pressure groups in the country — and, more recently, an attempt to understand the lack of interest in wildlife which is apparent in the country's development of its natural resources. Brazil's politicians and administrators, he feels, are 'frightened by nature', and so he has turned to studying the development of the concept of the 'forest' in school children throughout the country.

This survey is still in its early stages, but Machado has already found that the child's concept of the forest, and its association with fear, begins to form early in life. It seems to be based on nursery rhymes and children's stories imported from Europe and North America, which emphasise the dangers of going into the woods.

In the younger child this ignorance can be easily counteracted. Drawings and paintings of the 'forest' made by 7-10 year olds commonly included aeroplanes spraying the undergrowth with bullets and napalm; but after the same children had been taken by Machado on a trip to the real forest these were replaced by birds and butterflies, and the children paid far more artistic attention to leaf forms and flowers.

At the present rate of development Brazil's forests may only survive for another 30 years, but if Machado's children can be so easily convinced of its value there is some hope that this new generation may allow it to stand for longer. The final decision may perhaps lie with the teachers rather than the politicians.

news in brief

Third World space science institute proposed: An International Institute for Space Science and Electronics, where scientists from developing countries can carry out front line research in radio science, electronics and space applications, may soon be set up in Kenya. Establishment of the institute was strongly recommended by a recent workshop in Ooty, India attended by scientists from ten developing nations and organised by the Tata Institute of Fundamental Research's Radio Astronomy Centre. The new institute's first project will be the construction of a $20 million Giant Equatorial Radio Telescope (GERT). Nobel Laureate Anthony Hewish of the UK Cavendish Laboratories, consultant to the workshop, said he was strongly in favour of the project which he thought was "good and sensible". GERT will be the world's earliest warning system for geomagnetic storms and will also carry out pulsar research, make rapid surveys and give information on the structure of radio galaxies. According to Hewish, GERT's research is unlikely to be repeated in other countries because it will use wavelengths of around 300 MHz whereas most other research in this area tends to use shorter wavelengths. Developing nations should be able to finance the project themselves using technology within their capabilities. India, Kenya, and Nigeria have expressed strong initial interest in the project.

US trade unionists oppose expansion of nuclear power: Twenty US trade unionists, including the presidents of two international unions, have issued a statement calling for an end to the development of nuclear power. They accuse the nuclear industry of using "scare tactics" in threatening that such a move would cause widespread unemployment. Attitudes towards nuclear power within the US trade union movement are sharply divided, largely because the construction and operation of nuclear power stations provides many jobs for the members of a number of powerful unions. However the recent letter, represents a growing awareness among trade union members of the hazards as well as the advantages of nuclear power.

Of the 20 signatories of the statement, five are union members who live and work near the Three Mile Island nuclear plant. In addition to ending the development of nuclear power, the statement demands: guaranteed new, safe jobs at full union wages, with paid retraining to all now employed in nuclear or nuclear-related industries; a substantial shift of investment resources and workpower to conservation, clean and safe coal, and solar energy; and local, democratic control of energy sources, production and distribution.

Computer scientists continue strike: Computer specialists in the telecommunications section of the UK Postal Service voted overwhelmingly last week to continue their selective strike in the telephone billing department. They also voted to censure the leadership of their union, the Society of Civil and Public Servants, for recommending acceptance of management pay offer of 18½%. The union has been on strike since March in support of a pay claim for parity with professional engineers in the Post Office and with administrative grades in the Civil Service Department. The strike has been joined by the Civil and Public Service Association representing 34,000 clerical grades including computer operators. A total of 100 people are on strike and are being supported by a strike levy on the 40,000 members of both unions.

Academy panel calls for new "microstructure science" research programmes: A panel of the US National Academy of Sciences has warned that the development of micro-electronic technology appears to be outstripping the basic scientific knowledge on which such technology depends. It recommends the setting up of a number of new research programmes, primarily in universities, in fields that it calls "microstructure science and engineering". The academy panel also encouraged greater collaboration between university and industry laboratories, as well as an increase in programmes of non-proprietary research and development in industry. *Microstructure science, engineering and technology.* Solid State Sciences Committee of the National Research Council.

Getting steamed up over waste heat: Combined heat and power (CHP) could account for a third of domestic heating next century, according to a Department of Energy report published last week. The report estimtes that CHP saves between 2% and 9% of all primary energy consumption when it is fully operative by utilising waste heat from modern power stations. Extracting this heat at high enough temperatures provides space heating and hot water for domestic, commercial and public buildings. CHP is likely to be a viable economic option for district heating in areas with a net heat load density above 15 megawatts per square kilometre and so can be used for 80% of the heat load in Greater London, West Midlands, Greater Manchester, Merseyside and Glasgow. CHP's potential role in industry is limited since 70% of electricity generated is already associated with heat recovery. For CHP to be successful by 2000, investment must begin immediately, and it will have to compete with other fuels, particularly gas, for funding during the next 10-20 years. *Combined heat and electric power generation in the UK.* HMSO £3.75

French agronomists protest over potential redundancies: Scientists at the Institut National de la Recherche Agronomique, an organisation which supports most of French agronomy research and employs 7,000 people, recently locked up their director-general for several hours in an angry protest against a change in the institute's status that could lead to redundancies. The French government intends to change INRA into a group of specialised subsidiaries to exploit commercially certain results of agronomy research. The government is concerned about the increasing penetration of the French agricultural and food processing industries by British and Dutch interests. The trade unions involved see two dangers in the proposal: a reduction in fundamental research in favour of more development oriented research and less security of employment. INRA's researchers currently have the status of *fonctionnaires* (civil servants) and under the modified statutes they would lose the guaranteed employment that they now have.

What changed Sir Richard's mind? The government appears to have found a respectable volunteer to fly a kite for its plans, already mentioned in the press, to eliminate some of the less prestigious universities and polytechnics. Sir Richard Way, the Crown-appointed principal of King's College, London, who previously ran London Transport, made an astonishing *volte-face* in his speech at the recent exhibition to celebrate 150 years of the college. A press release prepared before the opening ceremony contained the unsurprising claim that new cuts in university expenditure would "probably make it impossible for the British university system to maintain the high standards at which it had always aimed."

However, when Sir Richard arrived in the company of the Education Secretary, Mark Carlisle, to open the exhibition, he announced that he did not in fact consider the universities as a whole to be short of money (12 July, page 97). Sir Richard went on to hark back to his days at the War Office when a shortage of money led to a painful reduction in the number of battalions by a process of amalgamation. Sir Richard made it clear that he considered a similar solution appropriate to higher education so that centres of excellence should not suffer.

Nature Vol. 280 2 August 1979

The Israel-Egypt peace treaty has opened up the possibility of scientific links. Here, 'Nature' correspondents describe the views from Cairo and Tel Aviv

Egypt: divided and uncertain

THE Egyptian scientific community is divided on the issue of collaboration with Israel. A small number of high ranking scientists see many advantages in undertaking joint projects; they argue that the Israelis have certain expertise in research areas that are important to Egypt, and Egypt should take advantage of the Israeli offer to collaborate in these areas.

There is, however, considerable opposition to this view from the rank-and-file scientists. Their argument is that the essential need of Egypt is not expertise but funding. If Israel can fund Egyptian research ventures, all well and good; but that's where collaboration ends. The Americans and Europeans already occupy positions of prestige in Egyptian scientific establishments as advisers and consultants, and many Egyptian scientists fear that Israelis will be added to the list. And they consider this not so much collaboration but more a form of domination.

Over the last few years, the Egyptian scientific community has been looking more and more towards the Arab OPEC countries as a major source of funding. A number of Egyptian projects in solar energy, desalination, oceanography, pollution studies and agriculture are already being financed by some of these countries, while Egyptian scientists and technicians form the backbone of industry and academia in Saudi Arabia, Kuwait, Bahrain and the United Arab Emirates. Despite the Arab boycott of Egypt, these scientists continue to work in Arab OPEC countries, many joint projects still continue, and these countries continue to recruit scientists and technicians from Egypt. The expectation of further collaboration with Arab OPEC countries is, therefore, much stronger than the possibility of co-operation with Israel. Many Egyptian scientists believe that co-operation with Israel will seriously damage the possibility of further collaboration with the Arab OPEC countries.

Dr Fahamy Ramadan, Secretary General of the National Research Centre of Cairo, sums up the feeling of many Egyptian scientists when he says: "All Arabs are brothers. Brothers fight; but they do not stay divided for long. They eventually make up. Our Arab brothers will make up with us, and much sooner than most people think". It seems that most Egyptian scientists would rather wait for their "Arab brothers" to make up with them then actively collaborate with Israel.

Ziauddin Sardar

Sinai 1967: can the battlefront now become a symbol of peace and co-operation?

Israel: a one-sided love affair

DISCUSSIONS about scientific and technological co-operation between Israel and Egypt have so far been very much like a one-sided love affair; while dozens of Israeli professors and politicians have spoken about the potential benefits of such co-operation little response has been forthcoming from their counterparts in Egypt. To be sure, there have been unofficial meetings between top Egyptian and Israeli scientists in third countries like the US and Germany usually on the initiative of well-meaning intermediaries. But so far the Egyptians have avoided public statements on the subject.

Yet the Israelis go on hoping and talking. The most dramatic presentation of a co-operation scheme was made some two months ago during Sadat's visit to Beersheba by Joseph Tekoah, former Israel ambassador to the UN and new president of Ben-Gurion University of the Negev. Speaking at an internationally televised campus ceremony, with Begin and Sadat on either side, Tekoah announced that the university had decided to establish a $100m fund for desert research of potential benefit to both Israel and Egypt. Egyptian scientists, he added, were invited to participate in the research projects and in the fund's administration. Sadat was all smiles, but that — so far — has been the only Egyptian response.

Slightly more guarded was the recent statement by Haifa Technion president Amos Horev, who expressed the Technion's willingness to enter into bilaterial relations with Egyptian institutions. As a first step he expected that Egyptian technological and science university graduates might study for higher degrees at the Technion, and that Egypt might wish to utilize the Technion's research laboratories and testing facilities. But under no circumstances, Horev warned, should Israelis delude themselves into thinking that they were goiong to 'save Egypt'.

The most logical place for co-operation to begin would be the Sinai peninsula, where for the last 12 years Israeli scientists have done extensive research, the results of which are now being turned over to the returning Egyptians. This is by no means a new idea, as a number of American Presidents, beginning with Eisenhower, have suggested the establishment in Sinai of joint Israeli-Egyptian power stations and desalination plants. Before this scheme was finally shelved, scientists working at the Oak Ridge National Laboratory under Dr Alvin Weinberg had produced a detailed report on how it could be carried out. They envisaged the installation of two reactors with a combined output of 1000 MW, which would provide power for new industries producing chemicals, fertilizers, plastics and aluminium, as well as for desalinating enough water to irrigate 300,000 acres of land in Egypt and the Negev desert.

These plans still exist, as do new ones engendered by the euphoria of peace. Yet the Egyptians remain reticent, as is evident in the experiences of an Israeli scientist who has just returned from a visit to Egypt. He travelled there on a second, non-Israeli passport, but his hosts, top figures in the Egyptian scientific establishment, know that he lives in Israel, as does anyone who reads his papers in the journals. Behind closed doors the Egyptian scientists spoke enthusiastically about the possibility of co-operation with Israel in spheres like agriculture, medicine, solar energy and desalination. Yet when someone came into the room, such discussions stopped and the guest was introduced as being from Europe.

In order to overcome this apparent Egyptian hesitance about bi-national co-operation, leading Israeli scientists have suggested that international organizations should sponsor large scientific conferences in Israel and in Egypt, where it is hoped there would be massive participation of Israeli scientists when the meeting took place in Egypt, and of Egyptian scientists when it was in Israel. Moreover, people here place great stress on the need to choose topics where the Egyptians excel and can teach the Israelis, as well as fields where the opposite situation exists.

Hungary steers a course without UN aid

Hungary's Academy of Sciences is now working out its Five Year Plan for 1981 — 1985, the first in which it will be entirely without the support of the United Nations Development Programme. For although by 1975 the Hungarian economy had passed the formal criterion for a 'fairly well-developed country', careful management of the UNDP funding ensured a certain carry-over beyond the official termination date. Furthermore, careful negotiation with the UNDP administrators cut down the expenditure on administrative overheads, so that an unusually high proportion of the funds available actually went on the equipping of Hungarian science, rather than on the expenses and infrastructure associated with the presence of international 'experts'.

A leading figure in these negotiations was Dr Bruno Straub. A biochemist of some renown, since the mid 1960s he has had an impressive second career as an administrator for scientific projects. In 1969, he was appointed a Vice-Chairman of the International Atomic Energy Agency committee for working out a nuclear safeguard agreement, and after the withdrawal of the chairman, Kurt Waldheim, from active participation, he took over as *de facto* chairman. In 1971, he was elected to the executive board of the International Council of Scientific Unions, serving on its Environmental Commission. And in his native country, Dr Straub applied his skill and renown as an organiser of science to a problem which, as a biochemist, he felt to be a major priority — the sad state of Hungarian biology.

Since the Hungarian economy is considerably dependent on agriculture, the development of the country's biological expertise seemed to him a matter of pressing concern. Unfortunately, in the mid-1960s, Hungarian biology was firmly in the hands of what Dr Straub described as "the old people". These, he explained, were "biologists and zoologists, only interested in systematics and taxonomy". Such an attitude, Dr Straub explained, found a certain support among the administrators. Not for ideological reasons — Lysenkoism never took hold in Hungary and the principle of a free inflow of information always held good.

The problem was simply one of finance. "You can do taxonomy cheaply, but experimental biology means instrumentation. You can get simple things here in Hungary or else from Poland — but sophisticated work means dollars; and that means a special decision of the government."

By tapping the UNDP aid to Hungary (about $1 million per year over five years), it became possible for the Academy of Sciences to construct and equip a modern biological research centre at Szeged with four institutes — biochemistry, biophysics, plant physiology and genetics, with a fifth institute, enzymology, sited in Budapest. Between 1973 and 1978, the Szeged Centre received some $1.2 million from UNDP, more than 50% of which was spent on equipment, with the participation of foreign experts reduced to "just those who could really help us".

In return for this special arrangement, Hungary had to undertake to give scholarships at Szeged to trainees from developing countries, to whose problems Hungary is still fairly close. Dr Straub, who had accepted the post of General Director of Szeged in 1973, on the understanding that it should be a rotating leadership between the five sections (he resigned in 1978), was able to persuade the Academy of Sciences to support this scholarship scheme. "While the UNDP money was still coming in, they were quite keen about it", he explained, "now they are a little less happy, but still, the scholarships continue". Luckily for intending applicants, the working language at Szeged is English, and the third-world trainees at present include representatives of Vietnam, Korea, a number of African countries, and (so goes the Szeged joke), a citizen of Lancashire.

Research at Szeged varies from basic investigations of immunological reactions in blue-green algae, through studies of the genetic basis of nitrogen fixation (with relation to lucerne, Hungary's most important legume), to contract research funded by agricultural concern. According to Dr Farkas, Director of the Institute of Plant Physiology, such contract work can raise the salary of those involved by up to 10 to 50% — though not, unfortunately, his own, since Directors and Vice Directors of Academy Institutes are not allowed to accept contract payments. The government, he explained, is trying to bring in material incentives (ie bonus payments) in a number of aspects of scientific life, both for economic reasons ("it works out cheaper in the long run") and also to stimulate creativity. He himself was not entirely happy about the contract scheme, he said, pointing out that many people would prefer to see a regular increase in basic salaries. Work for the agricultural cooperatives, such as the current project on the technology of vegetative propagation of vine-stocks, was "a burden, but beneficial". Nevertheless, he intimated that he would not be sorry if the Academy were to reverse its present policy on bonus payments, by setting a limit as to how far an individual scientist can augment his salary. Otherwise, there might be a real danger that scientists would be distracted from their main line of research.

Whatever the temptation at the laboratory-floor level, Hungarian science does not intend to abandon fundamental research. According to Dr Istvan Lang, Deputy General Secretary of the Academy of Sciences, fundamental research accounts for some 14% of Hungary's total R & D costs. "We think we must keep it at this level, and the state budget gives it a long-term guarantee."

There is no question of a cut-back; the main problem is what sort of fundamental research should be carried out. Hungary, he said, with about 0.9% of the total world capacity for research, clearly must be selective, and has tended to concentrate on fields in which Hungarian scientists had already made a name — mathematics, physics, and biochemistry. Within these fields, there is a certain amount of "target orientation". For example, Hungary wants to develop the pharmaceutical industry. "Hence we hope that a young biologist will choose his work with this in mind, rather than getting attracted to space biology, say!" (Though Hungary does, in fact, have a space biology programme, as well as a five year project at Szeged on the asymmetry of living matter, now being phased out in the words of its director, "until we find another living system or make life artificially, to provide material for comparison".)

Responsibility for science planning is divided between the Academy of Sciences and the National Committee for Technical Development, both of which are subordinated to the Government Science Policy Committee, headed by Gyorgy Aczel, one of the Deputy Prime Ministers. Policy decisions taken by the Science Policy Committee are binding on the Academy, Secretary Lang explained, "But what you have to understand is how our planning system works. We are a centrally planned economy, but we don't plan everything centrally."

As an example of academic freedom, Hungarian style, he cited his recent work for a special council to decide on future development of the Lake Balaton area. "When I was elected head of the Council, I chose as our first task the evaluation of all existing data, and the preparation of recommendations to the Government. These were discussed and approved by the Council for the Environment and Nature Conservation. Next a regional development plan was elaborated on the basis of these recommendations".

"Our forecasts shocked public opinion," he continued "We had to point out that if nothing changed, if the input level remained the same and the rate of control the same, then in 15 years' time, Balaton would be green with eutrophication and unacceptable as for leisure use".

It is, perhaps, not a matter of great surprise that the new plan was accepted on June 10.

Vera Rich

Fine-tuning for British technology — or will political pressures put a spanner in the works?

The Finniston report on engineering and education could be crucial for the UK's industrial revival, but its proposals may run counter to Conservative policy. **Robin McKie** reports

BRITAIN'S recently-elected Conservative government is facing a dilemma that could expose basic contradictions between its much-publicised antipathy towards public spending and its equally well-proclaimed desire to boost the country's industrial growth. The predicament will come in the form of the Finniston report, a major policy document now being completed by leading industrialists and educationalists, which will recommend a package of proposals for regenerating scientific and technological impetus within the UK's manufacturing industry.

At the centre of these plans lies the proposed formation of a British Engineering Authority which would take over engineering education, training and research throughout the country. Such a body would also be responsible for the registration of engineers, in the same way as the General Medical Council handles the registration of all UK doctors, and may even take on the role of granting licences for engineers wishing to act as industrial consultants.

However, given the new administration's recent moves to scrap a thousand similar 'quasi-autonomous non-governmental organisations' (or quangos as they are affectionately known), it is hard to envisage them allowing any increased public control of the private sector — particularly in view of the Conservatives' election pledge to leave industry alone "to get on with the job".

Corrective measures are badly needed, nevertheless, for it is now widely accepted that Britain's manufacturing industry is not as competent, efficient or productive as our foreign competitors. In particular, companies are accused of very poor intakes of scientists and engineers into management — a tendency which discourages further gifted and ambitious students from such a career route. This means a resulting intake of poorer engineering and technolgical students, with even worse prospects of reaching management — and so the spiralling problem becomes more critical.

Indeed, it is a crisis recognised by the new Minister of Science, Mr Neil Macfarlane, who believes that UK industry has shown scant regard for scientific and engineering talent in the past. "I think it is greatly to be regretted that the engineer and the scientist are generally relegated to a secondary level in the hierarchy of any industrial organisation in the UK. We have been taken over by financiers and lawyers", he said in a recent interview with *Nature*.

With such difficulties in mind, the previous Labour government set up the committee of inquiry into the engineering profession, led by Sir Monty Finniston, head of Sears Engineering and former chairman of the British Steel Corporation. Its task was to review:

- British industry's requirements for supplies of engineers;
- The role of engineering institutions in controlling standards of qualifications;
- The advantages and disadvantages of registration and licensing of engineers;
- Comparable arrangements in other countries, particularly in Europe.

But Sir Monty and his committee deliberately chose to interpret this remit in the widest possible terms and have set about preparing an entire blueprint for ensuring industrial regeneration in Britain. This is not to be done on the macro-level of gross economic distortions (as in recent budgets which have attempted major inflations of markets and profits), but by tinkering at a micro-level to fine-tune the country's industrial engine and prepare it for improved performance.

A central part will be played by the proposed British Engineering Authority which will take over the role of registration of engineers. At present this task is performed by the Council of Engineering Institutions, a central body made up of representatives of the country's many engineering institutions (such as the Institution of Electrical Engineers and the Institution of Mechanical Engineers) which specify, approve and enforce the minimum standards of professional conduct. Many now consider the CEI to be a weak, ineffectual body which merely awards chartered engineering status to anyone with a relevant degree at ordinary pass level. Instead, the new authority, which would probably include lay representation, would operate as a strong independent agency that would restore public confidence in the profession.

The new system would control the awards of titles — 'qualified engineer', 'qualified engineering technician' and a specially-created elite called 'diploma engineer' — only to those with sufficient training, experience and education. This would allow tight control over engineering practice by ensuring that those who fell below standard would lose their titles, and would make it an offence for them to continue to use these titles.

The diploma designation would represent a move towards creating an elite similar to the German 'superengineer', although this is more an attempt to boost the status of UK engineers than a bid to create a particularly practical type of engineer.

A further controversial plan being considered by the Finniston committee is a proposal that all university and polytechnic engineering courses should be closely scrutinised by the new authority — and that institutions failing to meet basic standards should be stripped of financial support. At present such an accreditation body operates in the United States, but it has no financial influence over university departments and only recommends to potential students and future employers those courses it believes are satisfactory. In considering this new, and far more radical proposal, the committee will be suggesting that the University Grants Committee and the Science Research Council be stripped of their present control of funding for engineering education and research — a move that would no doubt be strongly contested.

Indeed the proposal has already been

rejected by the main committee, but the sub-group on registration and licensing has since insisted that it be re-considered, stressing that a bold measure is necessary to swing education behind the interests of manufacturing industry. "We think that there are forces of inertia in higher education that will stand in the way of a reform of engineering education unless leverage is exerted", stated a recent report from the sub-group to the main committee.

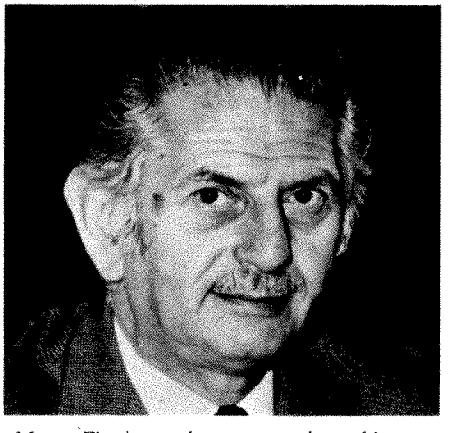
A further consideration that may influence the Finniston group is the likely constraint on future education spending. As increased resources are especially vital for engineering, the committee may recommend that the education sector is no longer a suitable outlet for funding and suggest a more fundamental alternative. This argument could find particular favour with the Conservatives, as it proposes moving money away from traditional public spending areas and closer to the interests of private industry.

The proposed British Engineering Authority would also monitor training schemes for graduates entering industry. At present, it is well-known that many smaller firms offer inadequate and inferior training programmes and such students would be at an immediate disadvantage upon the introduction of a strict registration system. This has been one important motivation behind the UK Science Research Council's launching of an experimental programme — to be known as graduate initial education — which will next year offer part-time postgraduate university-based instruction in industrial subjects for science and engineering graduates.

Thus it is envisaged that the BEA will maintain a strong hold over the flow of engineers into industry. Basic education would be monitored through an accreditation system; training would be controlled by close scrutiny of companies; and the actual quality of manpower would be governed through a tight registration system.

At the top end of the market, quality would be supervised by operating a licensing system for consultant engineers who offer special expertise in particular industrial areas. This would ensure the quality of those engineering experts who advise companies and public bodies and would act as a further qualification on top of registration.

These moves all reflect recognition that British industry is flagging not just because of poor investment in modern technology but also because it fails properly to utilise available talent and intellect. And even when this problem is overcome, systems will still have to be devised for professional, practising engineers to keep abreast of current technological developments. For example, many UK managers have an education which covers only transistor electronics; their lack of knowledge of modern solid state physics can lead to fears and prejudices about working with complex microelectronic technologies. The solution probably lies in various forms of continuing education courses, to be taken every five or ten years.



The extent of this problem has already motivated the Science Research Council to arrange technological topping-up courses — based at universities — for graduates of about ten years standing, and these are soon to be introduced into the UK. The Finniston committee is likely to favour a similar scheme which would also include grants for fares, fees and books.

Other proposals to boost the quality of personnel in industry will include methods for helping already-trained women engineers to get back into industry, and ways of improving attitudes towards industry in school classrooms. In this latter area, a particularly favoured plan is for interchanges of staff between schools and major manufacturing companies.

But such a scheme would not mean simply recruiting teachers from former industrial personnel — they may have left the commercial sector because they failed to operate adequately there. Instead a system of rotation of roles is seriously being considered, although it is acknowledged that this could cause difficulties with the trade unions involved.

In outlining these various proposals, the Finniston committee has recognised that one major problem has been the vast expansion of the British university sector in the early 1960s. This has led to colleges being elevated to university status, producing a more academic approach and forcing them away from local industries with which they previously had strong ties.

Now the Finniston committee is considering setting up regional engineering centres — to be run by the BEA — which would provide a mixing ground for academics and industrialists. The centres would be based at universities but would have the explicit roles of co-ordinating and generating engineering research, applications and training in relation to the particular industrial needs of a region. Such institutions could be set up at Imperial College (London), Aston (Birmingham), Leeds-Bradford, and Glasgow-Strathclyde universities.

Monty Finniston: due to report later this year

Another problem caused by university expansion has been the diverting of most engineers into degree courses meant for chartered engineers — those concerned with the innovation and creation of new technologies. The old college and part-time routes which provided the country's many technician engineers (those concerned with maintaining existing technology) are now virtually extinct.

As a result students who have received chartered engineering education have ended up totally unprepared as technician engineers. Finniston may consider introducing a new technician engineering degree course at universities to provide the most suitable education for those aspiring to the proposed 'qualified engineering technician' status.

At the moment, there is still strong agreement over the various issues between the 18 members of the committee and it is unlikely that a minority report will accompany the final publication of the full Finniston document. Indeed, one member, although slightly critical of the over-representation of academics and "fringe people" not directly concerned with industry, considered the committee had shown "a remarkable working chemistry" over the past 18 months.

The strength of this chemistry is likely to be tested in the new few weeks as work on the report is completed — for the committee is now under strong pressure to water down its recommendations, particularly from some engineering institutions who view a strong independent authority as a threat to their power and independence.

And within the committee, there are some signs of resolve weakening. In particular, there is now talk of finding a role within the BEA for the much-vilified CEI (because it has had past experience of controlling standards of education and training for engineers), although it had previously been agreed there would be practically no room for the CEI in the new authority.

This is only a small indication, but it could spell a warning that Finniston, in the hope of preventing undue reaction and prejudice to the report, may fudge the available options. In turn this could give the Government an excuse to further water down the proposals, eventually rendering them totally ineffectual.

Such a dilution of Finniston's proposals could have tragic consequences for Britain. The country's industrial slump can be blamed squarely on the failure to take up technological innovations and to make use of scientific and engineering talent. No amount of tinkering with sterling revaluations or credit markets will alter this, and strong remedial action is urgently required. The Finniston report — to be published some time between September and December — represents the Government's chance to change Britain's future technological development for the better.□

Airey Neave Memorial Trust

SIR, — Many people have suggested to us that they would like to commemorate the life of Airey Neave, assassinated this year by a bomb in the Palace of Westminster (for obituary see page 433). Some have sent money now banked in a special account.

Since Airey Neave believed in the supreme importance of freedom under the law, we consider that we can achieve something that he would have held dear by creating a Trust to provide for research into the extent of personal freedom under national laws. This may include the provision of travelling scholarships. Candidates will be chosen after they have submitted a short synopsis of the scope of the paper they intend to write. The papers, embodying their research, will be published.

In promoting these studies, priority will be given to applications by candidates from fields in which Airey Neave had a particular interest; former pupils of Radley College or Abingdon School and graduates of Merton College, Oxford; holders of degrees in science or law; members of the legal profession; former prisoners of war; authors; Members or former Members of either House of Parliament.

The value and number of such scholarships will depend upon the amount of money received. Application has been made for the Trust to be registered as a Charity.

Those who wish to be associated with this appeal should send their contributions to The Airey Neave Memorial Trust, c/o The House of Commons, London SW1. Covenant forms will be available on application to the Trust.

Yours faithfully,

JOHN TILNEY (Chairman)
and the committee of the Trust.

London SW1, UK.

Costs of toxicity testing

SIR, — That ICI Ltd is spending £6 million per annum on its toxicity testing programme seems to underline the fears of smaller companies that the tests they are asked to undertake are too expensive. This is even more the case if we concede that these tests can be but a crude guide to the possible hazards to man. Still, the bankruptcy of a few firms and a reduction in innovation might be a small price to pay for the sensation of safety we all crave; in any case, as the new legislation applies to new chemicals, only the larger more affluent companies with new product developments are likely to be much affected.

Or are they? Mr Langley has suggested (5 July, page 9) that industry ought to be doing more, anyway, under the 1974 Act, and the new notification scheme merely records that defined work has been completed successfully. Is there an implication here that existing chemicals will be subject to the same testing arrangements? The logic of the Act suggests this ought to be so — and recent experience with monomers has thrown doubt on 'long manufacturing experience' as a safeguard on health, making it more likely that some experimental results will be needed.

In this case, the economic impact could be substantial and, because it is happening at a time when another world recession is expected, it could have even more profound effects than usual. It is time to establish some priorities. Let the Health and Safety Executive produce guidelines, not on how to test chemicals, but on how to select chemicals which require to be tested — unless they intend to deal only with new chemicals. Let us concentrate our resources on developing test procedures which effectively screen chemicals for the properties we want to avoid at all costs; and leave lesser hazards until we can afford to attack them. Above all, let us recognise that life is a hazardous and invariably fatal process which will surely survive twentieth century industrialism, if we keep our scientific 'cool'.

Yours faithfully,

D. M. CONNING

British Industrial Biological Research Association, Surrey, UK.

Attack on paranormal is unscientific

SIR, — It is surely profoundly unscientific to claim that "neither electro-magnetism nor any other scientific theory can explain" ESP phenomena as Taylor and Balanovski do (14 June, page 631). The most anyone can ever claim is that existing theories do not explain a phenomenon so far as they can see — someone else may be clever enough to find an explanation within existing theories, or to discover a new explanation. The latter possibility is not "ruled out" by the "successful reductionist approach of science," but is probably the main attraction of science to its practitioners. To go on to deduce that an argument of this sort casts any light on whether the phenomenon exists is even more bizarre — would they have argued against the heat of the Sun before relativity and the theory of fusion? Or do they now assume there is doubt that the mu-meson is heavier than the electron because no-one has yet suggested an explanation?

It might be instructive for these authors to study the history of the famous argument over the age of the Earth at the end of the last century. Kelvin had calculated the age from the time taken for cooling; the result was far too short to allow species to have evolved. Biologists suggested Kelvin might have ignored some unknown source of energy, and were roundly mocked by the physicists for being "unscientific". The fact that Kelvin's proponents were both confident and arrogant did not prevent them being wrong — as the subsequent discovery of radio-activity proved.

I might add that I do not believe there is much evidence for ESP, but this is based on the absence of unambiguous experiments rather than on anyone's inability to think of an explanation.

Yours faithfully,

M. WHIPPMAN

London SW20, UK.

West Germany does not pursue Berufsverbote

SIR, — Your note "German psychologists issue study of Berufsverbote" (31 May, page 363) is utterly misleading. The West German government does not pursue a policy of Berufsverbote. Nobody is banned here by the government to enter any profession of his choice. The federal and state governments reserve the right to select those who apply for employment as civil servants, a status that provides life-long job security. I cannot see anything illiberal when the federal and state governments reject civil service status to a handful of totalitarian radicals. To proceed differently would endanger the liberal system in any western democracy. In my opinion, the slogan Berufsverbote is an infamous lie, cleverly invented by leftist totalitarians to discriminate against the most liberal political system that has ever evolved in the rather sad course of German history.

Yours faithfully,

F. MILLER

University of Munich, West Germany.

Degree-day values

SIR, — In a recent issue of *Nature* (14 June, page 565) the potential value of the 'degree-days' measure was indicated. Readers who wish to obtain degree-day values for the UK may be interested to know that such information is available in *Energy Management*, published by the Department of Energy; and is also reproduced in *Energy Digest*, published by Allens (Clerkenwell) Ltd.

Degree-day users requiring early figures may obtain these from the EQAS service (Freefone 3140, or 8305 in Scotland). Detailed information is available in the free booklet *Degree Days*, available from: Library, Department of Energy, Thames House South, Millbank, London SW1P 4QJ.

Yours faithfully,

P. A. WOOD

Newport Pagnell, Buckinghamshire, UK.

The caddish salamander

SIR, — The vocabulary available to sociobiologists includes altruism, nepotism, selfishness and spite, but is still incomplete. Arnold (*Z. Tierpsychol.* **42**, 247; 1976) describes how a male salamander (*Amblystoma*) may intrude between the members of a mating pair, imitate the female, and induce the rival male to release a spermatophore which is then covered with the intruder's own sperm; the latter achieve fertilisation. For this I propose the term *caddish* behaviour.

Yours faithfully,

S.A. BARNETT

Australian National University, Canberra, Australia.

Erratum

In the issue of *Nature* of 21/28 December, page 754, in a letter by Drs Karlson and Dixon on biochemical nomenclature, the word 'bisphosphate' was twice misprinted as biphosphate in the last two lines of the third paragraph. The authors were pointing out the distinction between 'diphosphate', indicating a single diphosphate group in ADP, and 'bisphosphate', indicating two separate substitutions — as in fructose 1,6-bisphosphate.

news and views

Decline of the calcium hypothesis of visual transduction

from P. Fatt

IN a recent issue of *Nature* (Miller & Nicol **280**, 64; 1979) and in this issue (Robinson & Hagins, page 398) papers appear which are concerned with the involvement of guanine nucleotides in the action of light on the photoreceptor. In both the authors seem somewhat reluctant to discuss how their findings might fit into an overall mechanism of visual transduction. This reticence is a recently acquired characteristic of workers in the field, for which readers may wish some explanation.

What has happened is that over the period 1972–78 thinking about visual transduction in the vertebrate has been dominated by the 'calcium-as-the-intracellular-transmitter' hypothesis, proposed by W.A. Hagins (*A. Rev. Biophys. Bioeng.* **1**, 131; 1972) and strongly supported with experimental evidence by him, (see refs in Robinson & Hagins (this issue); Miller & Nicol *Nature op. cit.*) his coworkers and others (see *Vertebrate photoreceptors* (eds Barlow & Fatt) Academic Press, London, 1977). In the case of the retinal rod outer segment, which contains a stacked array of flattened sac-like disks, enveloped by but separated from the surface (or plasma) membrane of the cell, the hypothesis is made up of the following elements. (1) There exists a capacity for pumping Ca ions from the cytoplasmic space (that is, the space internal to the surface membrane but external to the disk) across the disk membrane to the intradiskal space where they are accumulated. This pumping is not directly dependent on the state of the visual pigment (rhodopsin), but is regulated by the concentration of Ca^{2+} in the cytoplasmic space. Operation of the pump requires metabolic energy (which Robinson and Hagins now suggest is provided by hydrolysis of guanosine triphosphate (GTP) to the diphosphate (GDP). (2) At some stage in the thermal conversion of the visual pigment molecule that follows photoisomerisation of its chromophore (that is, on bleaching), a pore is created in the disk membrane through which Ca^{2+} can penetrate, so that there occurs a nett passge of these ions along their electrochemical gradient, from the intradiskal to the cytoplasmic space. (3) Calcium ions, diffusing about in the cytoplasmic space, act to block pores in the surface membrane which permit the passage of Na^+ between the extracellular and cytoplasmic spaces.

I suggest that a major reason why the hypothesis has now fallen out of favour is the excessive enthusiasm with which it was previously advanced. In its heyday it was offered as the complete explanation of visual transduction. This ignored complications at both (2) and (3) of the hypothetical mechanisms. Measurement of the electrical properties of rods (Falk & Fatt *J. Physiol. Lond.* **299**, 195; 1973) gave evidence that pore formation in the disk membrane did not follow directly the bleaching of rhodopsin; the number of rhodopsin molecules that could be engaged in the process over a period of 10 min was limited to 0.05–0.1 of the number initially available for bleaching. Also, the ability to create pores was lost when the surface membrane was damaged, implying that some diffusible material was required. The attribution of a direct role to Ca^{2+} in blocking the Na pores of the surface membrane also had its problems. Ca ion might act either by entering the pore and so clogging it or by combining with a nearby membrane site so as to alter the electric field at the cytoplasmic end of the pore. However, by neither of these means would the Ca^{2+} released from the disks be likely to be as efficacious as quantitative application of the theory required. An indirect mode of action would be less demanding.

In a scheme that has recently come to the fore and is investigated by Miller and Nicol (*Nature op. cit.*) the role of Ca^{2+} is envisaged to end in the activation of the enzyme phosphodiesterase (PDE) which catalyses the destruction of cyclic guanosine monophosphate (cyclic GMP), which is in turn required for activation of another enzyme that leads eventually to opening of Na pores in the surface membrane. Miller and Nicol examine the control of the Na permeability of the surface membrane by experimentally introduced cyclic GMP and observe the latter's destruction by light-induced activation of PDE. The authors make a passing reference to Ca^{2+} as among the possible activators of PDE.

Robinson and Hagins also give the Ca hypothesis a sideways acknowledgement. This time Ca^{2+} is mentioned as a possible candidate for the transmitter substance, which when pumped back into the disks after its release is considered to account for the observed hydrolysis of GTP to GDP with a time constant of decay of about 10 s following flash illumination. There is also a smaller component of GTP loss attributed to an accelerated turnover of cyclic GMP. As the authors point out, their most unexpected finding is a change in the state of binding of GDP occurring within 4 s of the flash (and possibly within a much shorter period). One may presume this to be related to events taking place in the disks. On the Ca hypothesis the binding of GDP would be involved in the creation of pores in the disk membrane. What is surprising is that the magnitude of the effect is such that some 50 GDP molecules are taken up for each rhodopsin molecule bleached. The question then arises whether all 50 molecules are required to create a single pore or whether the bleaching of a single rhodopsin molecule results in 50 pores, providing chemical amplification.

The latter question leads to the immediate cause of the decline in popularity of the Ca hypothesis. During the past year Liebman and Pugh (*Vision Res.* **19**, 375; 1979) have proposed a model of visual transduction in which events between bleaching of rhodopsin and activation of PDE are considered to take place through the diffusion and chemical interaction of these and associated molecules in the disk membrane. An initial stage of chemical amplification is proposed, its gain being given by the ratio of PDE molecules activated to rhodopsin molecules bleached, a number which may well be the same as the factor of 50 found for GDP uptake. In this model there is no role for the pumping of Ca^{2+} or any other transmitter substance across the disk membrane, nor for the creation of pores in the membrane consequent on the bleaching

P. Fatt is Professor in the Department of Biophysics, University College, London.

©Macmillan Journals Ltd 1979

of rhodopsin. Liebman and Pugh attempted to test the Ca hypothesis and claim to have falsified it by measuring light-induced hydrolysis of cyclic GMP in the absence of free Ca^{2+} and showing in a quantitative argument that the observed rate of hydrolysis is of the correct magnitude to account for visual transduction. On the strict application of the scientific method, this should signal the abandonment of the Ca hypothesis. The numerous experimental findings on the involvement of Ca^{2+} in the response of rods to light, as well as the existence of pumping activity and a light-induced permeability increase of the disk membrane, would have to be relegated to the status of inconsequential side-effects. But science, especially biology, does not always work that way. The reason it does not in the present case is that the system under investigation is unlikely to be as simple as the model of Liebman and Pugh attempts now to represent it, or as the Ca hypothesis did earlier. There is in addition the disturbing factor that the biological material on which the different studies have been made is not the same. Liebman and Pugh used finely fragmented rods to examine the behaviour of separated disks, whereas studies in support of the Ca hypothesis have often been constrained to use undamaged rods in order to yield results consistent with the hypothesis. Under these circumstances the hypothesis has not been quite abandoned, as the letters of both Miller and Nicol, and Robinson and Hagins show. One may expect that it will continue to fare thus until further investigation either causes it to drop from sight completely or permits its reassertion as its rival encounters difficulties. By then, perhaps, its limitations will be better appreciated. □

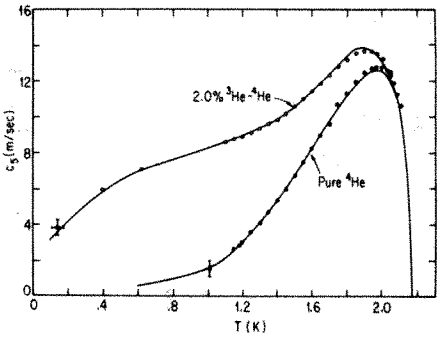

Fig. 1. Experimental values of the fifth sound velocity C_5 (points) compared with the theoretical predictions (full curves) for pure ^{4}He and a dilute ^{3}He - ^{4}He solution, plotted as a function of temperature (T). (From Williams, Rosenbaum & Rudnick *Phys. Rev. Lett.* **42**, 1283; 1979).

New wave of superfluid ^{4}He

from P. V.E. McClintock

A NEW type of propagating wave mode has been found in thin films of superfluid helium-4. Christened 'fifth sound', its discovery is reported simultaneously by two separate research groups, writing in the same issue of *Physical Review Letters*: by Gary A. Williams, Ralph Rosenbaum and Isadore Rudnick of the University of California at Los Angeles (**42**, 1282; 1979); and by G.J. Jelatis, J.A. Roth and J.D. Maynard working at Pennsylvania State University (*op. cit.*, 1285).

At least four different types of wave motion were previously known to occur in liquid helium-4 below its superfluid transition temperature at 2.2 K. The reason for this extraordinary richness of the liquid's vibrational characteristics lies, of course, in the fact that it behaves as though composed of two quite separate but freely interpenetrating components, the normal fluid components and the superfluid component. The former has properties much like those of any other liquid whereas the latter, having zero viscosity and carrying no heat, is largely responsible for the well known exotic properties of liquid helium. Depending on the applied experimental conditions, vibrations can travel through the liquid in a number of different ways, each with its own name and characteristic (but temperature dependent) propagation velocity. The two components can move together (so-called first sound) or in antiphase (second sound) or the superfluid can be made to vibrate by itself while the normal fluid remains clamped in position, by placing the liquid helium in a porous medium (fourth sound). The newly discovered wave mode is a fairly close relation of third sound, which is a wave on the surface of a thin helium film.

A helium film quickly forms on any surface whose lower part dips into the liquid. It is typically up to 200 Å in thickness, depending on the height above the free surface in the helium bath or on the ambient pressure in the case of unsaturated films, and it can support long wavelength modes rather similar to gravity waves on the surface of a classical fluid, but with the van der Waals attraction to the substrate filling the role normally played by gravity. Because viscous forces clamp the normal fluid component and prevent it from moving parallel to the solid substrate, there will be a tendency for the wave to be accompanied by associated temperature changes: at peaks, where the film is thick, there will be extra superfluid and a lower density of heat-carrying normal fluid, corresponding to a lower temperature; at troughs, where the density of superfluid is depleted, the film will tend to be hotter. Normally, however, an additional mechanism comes into play and effectively irons out all such incipient temperature differences. The film is in thermal equilibrium with the surrounding helium vapour, and so a hot spot on the film results in increased evaporation leading to local cooling, whereas the vapour tends to condense preferentially on to any cold spots, thereby warming them. Thus a wave on the surface of the film is usually a pure thickness mode, not accompanied by any changes in temperature: it is known as third sound.

If, however, the evaporation/condensation phenomenon could somehow be inhibited, the wave would then be different in nature and would propagate at a quite different characteristic velocity, because of the additional restoring force arising from the temperature differential between the troughs and peaks. To this end, the Los Angeles and Pennsylvania groups have both resorted to experimental geometries in which the space available for the vapour is carefully restricted. The basic principle is that the separation between the surface of the helium film and the nearest other surface should be made smaller than the mean free path of helium atoms in the vapour. Under such conditions, the vapour is no longer able to transport heat in the direction parallel to the film. Thus the surface wave, instead of being isothermal as in third sound, becomes adiabatic, with temperature minima at the peaks and maxima at the troughs. For relatively thick helium films, where the surface is only weakly influenced by the van der Waals attraction of the substrate, the temperature differential provides the dominant force driving the wave and determining its propagation velocity. It is this thermally driven surface wave which has now been observed for the first time, and which is being called fifth sound.

The two groups used quite different techniques, however, for restricting the vapour. The Los Angeles group worked with standing wave resonances on helium adsorbed on fine alumina powder, compressed so that the average diameter of the pores between the particles was comparable with the mean free path of helium atoms in the vapour. The Pennsylvania group, on the other hand, have succeeded in setting up a more difficult, though conceptually more straightforward, experiment using travelling waves in which a flat plate is placed very close and accurately parallel to the substrate carrying the helium film. They used optically flat quartz plates, and achieved an average spacing of only 5 μm by sandwiching a few grains of powder between them to stop them touching.

In both cases the experimenters found a wave which had a propagation velocity

©Macmillan Journals Ltd 1979

much faster than that of third sound and, after making due allowance for certain complicating factors, they could deduce the velocity of fifth sound from the measurements. Results from the Los Angeles experiment are shown in Fig. 1. Agreement with the theoretical prediction (lower full curve) is quite remarkably good, and this clearly remains the case even when a little helium-3 is added to change the relative proportions of the normal fluid and superfluid components (the helium-3 contributing only to the former).

Fifth sound constitutes an interesting addition to the rich variety of diverse phenomena already known to occur in liquid helium-4. No doubt efforts will soon be made to observe an equivalent mode in the case of superfluid helium-3: for temperatures around 2 mK the mean free path of vapour atoms is effectively infinite and, to this extent (if not in any other), the experimental design will be simpler. □

Measuring weak absorption spectra

from T.F. Hunter

THE past decade or so has seen a major advance in our ability to measure very weak absorption spectra. Such measurements are needed for analysis of trace amounts of materials or for studying intrinsically weak transitions. In the latter category come vibrational transitions to high energy overtone and combination bands, say in the visible region of the spectrum, and of considerable importance to an understanding of chemical kinetics; spin-forbidden electronic transitions; and transitions due to non-linear coupling of the radiation field with a molecular system, for example, two-photon absorption.

Normal absorption spectroscopy, with its measurement of incident and transmitted intensities, can be of value in this area if sufficiently long pathlengths are used; turntable laser sources, allowing multiple-passage of the radiation beam to be set up more readily, have helped. However, very long optical pathlengths are awkward experimentally, and, in measuring the difference between the incident and transmitted beams, no distinction is made between absorption and scattering, a distinction which may be of consequence for very weakly absorbing samples.

Modern photo-electric detection systems measure the intensity of emitted photons with high sensitivity and, for some time, weak absorptions have been followed by so-called excitation spectroscopy where the intensity of emission is plotted as a function of excitation wavelength. For example, two-photon absorption studies in vapours (Hochstrasse *et al. J. Chem. Phys.* **60**, 317; 1974; Schlag *et al. J. Chem. Phys.* **66**, 386; 1977) have been studied with high resolution and sensitivity using fluorescence monitoring of this kind. However, many classes of compound show effectively no fluorescence because the dominant deactivation process from the excited state is a non-radiative coupling to other states and other forms of energy.

In any system where the quantum yield of emitted photons is less than unity (and this means essentially all systems), the non-radiative coupling leads to excess heat being produced following the absorption process. An increase in temperature or pressure in the system results. Two techniques, using this flow of heat energy, have been developed.

Thermal lensing spectroscopy (Gordon *et al. J. appl. Phys.* **36**, 3; 1965; Albrecht *et al. J. Chem. Phys.* **65**, 179; 1976) uses a powerful beam of radiation from a tunable dye laser for example. Following the absorption of some radiation by the weak transition under study, the temperature of the sample fluid rises; since the cross-sectional profile of the intensity of the laser beam is Gaussian in shape so is the temperature distribution. Such temperature variation leads to a concomitant variation in the refractive index, a phenomenon which constitutes a thermal lens. The laser beam diverges slightly due to the flow of heat energy. By intensity-modulating the incident beam and thus enabling lock-in devices to minimise interference from noise (thermal, optical, electrical), and by monitoring a part of the transmitted beam through a pin-

Eukaryotic transcription *in vitro*

by Eleanor Lawrence

IN an unscheduled talk at the recent ICRF Tumour Virus meeting* R. Roeder announced to an appreciative audience the development of an *in vitro* transcription system in which initiation of the adenovirus major late gene transcription unit at the 'correct' site has been unequivocally demonstrated.

He and his colleagues P.A.Weil, D.Luse and Jacqueline Segall at the Washington University School of Medicine, St Louis, have obtained specific initiation and transcription of part of the adenovirus late genes, using either full-length purified adenovirus DNA or restriction fragments containing the start of the transcription unit, in a system consisting of a crude extract (the soluble fraction, S100) of uninfected human KB cells to which purified human RNA polymerase II has been added. Purified polymerases II from other vertebrate cells are also effective but that from wheat germ is not.

Although still in a primitive state this *in vitro* transcription system promises to provide the means by which the basic requirements for the transcription of eukaryotic 'class II' genes can be determined. Class II genes are those transcribed by RNA polymerase II and include many of the single copy sequences in eukaryotic cells, as opposed to the ribosomal RNA genes for example, which are transcribed by RNA polymerase III.

Roeder has yet to test his system on other eukaryotic genes, but the close resemblance of the putative 'promoter' sequences for the adenovirus late genes to those of beta-globin and ovalbumin amongst others, suggests that the system may work equally well for them. Successful transcription of the adenovirus late genes in the absence of any components from infected cells is of particular interest as the late genes are not transcribed *in vivo* until replication of the adenovirus DNA has begun. This suggests either that these genes are being transcribed at a low level even early in infection, or, more attractively, that control over their expression is exerted at a higher level, that of chromatin organisation perhaps, and that these controls are bypassed when purified DNA is transcribed.

The site at which transcription starts *in vivo* has been mapped precisely (see Ziff & Evans *Cell* **15**, 1463; 1978) and so Roeder was able to determine that the 5′ end and oligonucleotide fingerprints of the RNA produced in his system matched those of transcripts *in vivo*. Although initiation is specific, transcription does not continue very far into the gene *in vitro* and is also slower than *in vivo*. So one task is to determine whether this premature *in vitro* termination can be overcome, by adding extracts from adenovirus-infected cells for example. The long term aim is gradually to refine the system until it is fully characterised (as with the *in vitro* assays for DNA replication developed for the small bacteriophages). Determination of which regulatory DNA sequences preceding and within eukaryotic genes are essential for faithful transcription is already well underway in the *Xenopus* oocyte transcription/translation system and more recently through the insertion of defined fragments of eukaryotic genes into mammalian cells using SV40 vectors. A fully characterised *in vitro* assay however, could also identify the array of cell proteins that might be expected to be needed.

Eleanor Lawrence is News and Views Editor of Nature.

hole onto a photo-cell, the resultant signal as a function of the radiation wavelength gives good spectral information on weak transitions. Absorptivities of around 10^{-4} cm^{-1} are readily determined, most measurements having been done on liquids.

The other technique, using the flow of heat energy, is that due to the optoacoustic effect. This effect is of long standing (Bell *Amer. J. Sci.* **20**, 305; 1880) and has been much used, especially in gas-phase studies, for examination of molecular relaxation processes, for example, vibrational–translational energy transfer, de-activation of triplet states and photofragmentation processes (Read *Adv. Mol. Relaxation Processes* **2**, 257; 1967; Hunter *et al. J. Chem. Soc.* (Faraday II), **70**, 1010; 1974; Hunter *et. al. Chem. Phys. Lett.* **58**, 291; 1978). the optoacoustic (OA) effect consists of detecting the oscillatory pressure changes in a system following absorption of intensity-modulated radiation. This is most commonly done in the gas-phase using condenser or electret microphones, and the combination of this technique with laser excitation has enabled the detection of trace gases with high sensitivity, of the order of 1 p.p.b. in many cases (Kreuzer *et al. Science* **173**, 45; 1971; Patel *et al. Appl. Phys. Lett.* **30**, 578; 1977). Absorptivities as low as 10^{-10} cm^{-1} have been measured. Such trace gas detection has normally been done at one, carefully selected, laser wavelength, but obviously, with tunable lasers, weak absorption spectra can be studied. The most sensitive arrangement is to have the OA cell within a dye laser cavity, where a high level of circulating radiation power is present, and high resolution spectra of methane and ammonia in the visible have been so obtained (Stella *et al. Chem. Phys. Lett.* **39**, 146; 1976).

Two recent papers in *Nature* by C.K.N. Patel and A.C. Tam (**280**, 302, 304; 1979) describe important extensions of the OA technique to the measurement of very weak absorptions in liquids. These authors have used as their periodic excitation source a pulsed tunable dye laser, with pulse width of 1 μs and pulse repetition rate at 10 pulses per second, and have developed a very useful pressure transducer based on a lead zirconate titanate cylinder which is submerged in the liquid. Accurate absorption data are given for pure water over the range 400 to 700 nm, and, perhaps more important, details of two-photon absorption in liquid benzene are presented both for linearly and circularly-polarised excitation. The high photon density, both in space and time, required for two-photon studies is achieved by using pulses and by careful focusing of the laser beam; the sample cell is external to the laser cavity.

OA measurements on liquids have been carried out before but in general have used the same technique as that used in the study of solid samples (Rosencwaig *et al. J. appl. Phys.* **47**, 64; 1976; McDonald *et al. J. appl. Phys.* **49**, 2313; 1978). The surface of the solid, or liquid, is irradiated and the periodic flow of heat is transmitted to a gaseous column containing the microphone. Although widely used in examining solids (several commercial instruments are available) where scattering is a major difficulty with other techniques, the OA method, with a gas as intermediary, has limitations in sensitivity and overall resolution. This is particularly true for solids of high thermal conductivity. The use by Patel and Tam of pressure transducers actually in the liquid, or, for solids, bonded to the surface and thus measuring the sound waves in the solid directly (Farrow *et al. Appl. Opt.* **17**, 1093; 1978), promises to be much more sensitive than the normal approach.

I have concentrated here on the use of the OA technique to measure weak absorptions; its use in the more specialised areas of energy transfer such as photofragmentation shows equal promise. As a detection system it covers all excitation wavelengths, the only requirement being that the excited states produced relax, in whole or in part, to heat energy; thus advances in laser technology (the production of fully tunable infrared lasers) and further improvements in the electronic ability to recover signals from noise will ensure progress in the range and sensitivity available. □

Implications of immunological heterogeneity of tumours

from Robert S. Kerbel

THE concept of 'tumour progression', coined some 25 years ago by Leslie Foulds, has stood the test of time. Its importance cannot be overestimated: to understand tumour progression is to understand why cancer is such a frustratingly difficult disease to treat. Simply stated, tumour progression is the process of independent, stepwise and permanent changes in the many different properties of a malignant tumour. Immunogenic specificity, karyotypic diversity, drug-resistance, hormone-dependence, metastatic potential, degree of cellular differentiation and conversion to ascitic growth are some of the properties which can change as the tumour develops. The process of progression is thought to have its basis in the continuous emergence of successive clones of tumour cell variants, one gradually replacing another, through the intervention of natural or artificial selection pressures.

Progression implies that a tumour cannot be simply a homogeneous population of malignant cells. The undoubted monoclonal origin of most tumours in turn implies an inherent instability (probably genetic, as argued persuasively by Nowell (*Science* **194**, 23; 1976)) which results in tumours continually throwing out mutant cells, a few of which have a selective advantage and become the progenitors of new clones which eventually predominate. The result is the slow but inexorable evolution of an increasingly malignant and autonomous tumour, one not subject to most of the normal constraints imposed by the host.

Immunogenic heterogeneity within a tumour obviously has profound implications not only for scientists studying the immunological relations between host and tumour but also for the practical application of specific immunotherapy, especially in relation to tumour recurrence and metastasis.

The first indications of immunogenic heterogeneity were provided by Prehn in 1970 (*J. Natn. Cancer Inst.* **45**, 1039; 1970) who established two sublines of cells with different antigenic specificities each derived from different fragments of tissue taken from opposite sides of a primary methylcholanthrene-induced mouse sarcoma. A pair of cell lines established in a similar manner from later serial passages of the same tumours did not differ, however. Prehn concluded that primary or early-passage tumours possess marked, random antigenic heterogeneity which can be lost during subsequent passage as the result of the immune selection exerted against the more immunogenic clone(s).

The importance of such results to the problems of tumour recurrence and metastasis were nicely illustrated by subsequent work performed in many laboratories. It is well known that if cells from established transplantable tumours are inoculated subcutaneously into mice and the resultant tumour removed early enough, the tumour does not regrow at the primary site. The animals also become highly resistant to a later injection of cells from the same tumour line. However, if primary methylcholanthrene rat sarcomas were surgically resected, secondary regrowths almost invariably developed at the resection site (Pimm & Baldwin *Int. J. Cancer* **20**, 37; 1977). Furthermore, cell lines established from such recurrent tumours were found to be immunologically distinct, as assessed by immunisation–protection experiments, from lines established from their original primary

0028—0836/79/310358—03$01.00

©Macmillan Journals Ltd 1979

sarcomas. Similarly, metastases, that is, tumour recurrences found at a site distant from the original tumour, may contain antigens different from those of the primary tumour, or may have lost some antigens completely — the so-called deletion mutants, for example (Sugarbaker & Cohen *Surgery* **72**, 155; 1972).

The significance of such immunological heterogeneity should not be lost on those who use established transplantable tumours to study the immunology of the tumour–host relationship. What it means in relation to the specific immunotherapy of experimental tumours is made abundantly clear by some recent experiments reported by Olsson and Ebbesen (*J. natn. Cancer Inst.* **62**, 623; 1979). They attempted to prevent the growth of AKR mouse thymic lymphomas (of recent origin), by repeatedly injecting young mice with irradiated AKR thymoma cells, after the recipients had been injected with untreated cells of a primary AKR thymoma. Not surprisingly, the procedure was generally unsuccessful; about 70% of the treated mice developed thymomas. What was surprising was that the thymomas which arose in these mice were immunologically distinct from those in untreated control recipients, as assessed by antibody and cytotoxic T cell assays. After analysing many tumours, the authors concluded that virtually all AKR thymomas are immunologically polyclonal, consisting of a dominant clone, and three distinct minor subclones — the latter group comprising less than 3% of the original tumour cell population. By treating animals with unfractionated thymoma cells, effective immunity is induced only against the dominant clone since the cells of any minor clone are present in too small a number to stimulate the immune system. This merely allows the cells of a minor or 'silent' clone to flourish, so that it eventually becomes dominant. When Olsson and Ebbesen treated their animals with a mixture of equal and large numbers of cells from each clone, so that effective immunity would be produced against all the clones, they produced a cure rate of greater than 90%.

These results also suggest that tumour progression may be more complex than previously thought. It may be that newly emerging clones do not always have to replace one another successively or die off. Rather, many may lead a chronic but cryptic existence, content to live in the shadow of the dominant clone. Only with a favourable change in the immunological *status quo* do they get a chance to flex their muscles.

It would be tempting to blame the failures of specific tumour immunotherapy on immunological heterogeneity and the existence of 'silent' subclones. There are, however, many who would say this is nonsense since most naturally arising tumours are not demonstrably immunogenic (Hewitt *et al. Br. J. Cancer* **33**, 241; 1976). Indeed, the Kleins have stressed the importance of the unrelenting process of tumour progression in the evolution of non-immunogenic spontaneous tumours, whereby successive immunogenic clonal variants replace each other as a result of selection, until a variant emerges which, lacking tumour antigens, becomes independent of the usual restrictions imposed by the immune system (*Proc. natn. Acad. Sci. U.S.A.* **74**, 2121; 1977). This remains a sensitive issue, and the antigenic properties of human tumours are still far from clear. Perhaps the extensive use of hybridomas to produce monoclonal antibodies against putative human tumour-specific antigens will help eventually to resolve this controversy (Herlyn *et al. Proc. natn. Acad. Sci. U.S.A.* **76**, 1438; 1979).

The non-immunogenicity of many primary spontaneous tumours and the polyclonal nature of those that are immunogenic, do not auger particularly

Is NGF an enzyme?

NERVE growth factor (NGF) is a protein with a key role in the growth and differentiation of immature sympathetic nerve cells and in the maintenance of fully differentiated sympathetic neurones.[1] Since its discovery in several organs, cell lines and body fluids, biochemists have faced the apparently simple but actually very difficult task of isolating and identifying the polypeptide responsible for such impressive biological action. Attempts to purify this 'molecule' from cell-free extracts have been hampered by the tendency of NGF to associate with other components of the homogenates. Thus the apparent size and sedimentation constant of the NGF 'molecule' have varied according to isolation procedures used. The molecular identity of NGF has changed from a protein of molecular weight 44,000 (ref. 2) to a component of molecular weight 40,000 which is strongly associated with other components of the extract so that together they elute as a protein larger than 100,000 (ref. 3). A form of NGF defined as 7S on the basis of its sedimentation behaviour has also been isolated and found to be[4] a mixture or complex of three proteins defined as α, β, γ. While γ is an enzyme with arginine esteropeptidase activity and α has no detectable biological or biochemical action, β is the only component of the complex endowed with nerve growth promoting acitvity. Subsequent studies suggested that the function of the γ component in an intact cell is to cleave a pro-NGF chain of larger size, as demonstrated for hormones such as insulin[5].

Finally, a 30,000 molecular weight NGF consisting of two identical polypeptide chains held together by non-covalent bonds was isolated in pure form and defined as 2.5S NGF[6]. The β and 2.5S NGF are almost identical proteins differing only in an N-terminal octapeptide with no detectable relevance to nerve growth promoting activity. This latter preparation has been sequenced and studied extensively[7]. All attempts to detect enzymatic activity in 2.5S NGF have given negative results.

In a recent article NGF has been reported to be a specific protease although the experiments supporting this conclusion leave room for doubt[8]. The authors isolated from the same source as that of the 2.5S or β NGF, the mouse salivary gland, a protein(s) with molecular weight of 116,000. In acrylamide gel electrophoresis in the absence of detergents or other denaturing substances, this protein(s) runs as a single band which exhibits a protease activity with an almost evanescent degree of specificity for plasminogen (880 ng of this preparation have an activity comparable with 0.083 ng of urokinase). The same band cross-reacts with antibodies directed against 2.5S NGF, a finding which is taken as evidence that NGF is a protease. The authors have overlooked the possibility that the apparently homogeneous 116,000 molecular weight component with protease activity, may be a complex of 2.5S or β NGF plus some other protein(s) easily identifiable with the many proteases present in the salivary glands. Their conclusion requires support from evidence obtained in carefully controlled dissociating conditions that the 116,000 molecular weight complex is indeed composed of a single polypeptide chain and is not a mixture of at least two different entities: one with properties of the 2.5S or β NGF but devoid of enzymatic activity and the other(s) with protease activity. The same authors while reporting this enzymatic property in the 116,000 molecular weight protein acknowledge that the 2.5S NGF alone does not possess such activity. Although all previous work indicates that NGF is associated in mouse salivary glands with proteases, this association is not evidence that NGF itself is an enzyme.

well for the future of specific immunotherapy. One possible route to overcoming this problem, as the Kleins have pointed out, is tumour cell modification effected by various artificial means. Another is to concentrate more effort on non-specific immunotherapy. The rationale is fairly simple: a few types of lymphoreticular cell, namely activated macrophages and natural killer (NK) cells, seem capable of spontaneously killing various kinds of tumour cell populations. Because classical antigens are not involved in the recognition process — at least as far as activated macrophages are concerned — variants resistant to this form of effector cell killing may arise far less frequently, if at all. Fidler, for example, has shown that it is possible to derive tumour variant sublines resistant to conventional lymphocyte-mediated killing by progressive selection *in vitro* (Fidler *et al. Cancer Res.* **36**, 3160; 1976); the variants appeared to have lost the tumour antigens (Fidler & Bucana *Cancer Res.* **34**, 3945; 1977). There are no reports (yet) of the derivation of similar macrophage-resistant (Mac^R) variants. Whether this is from lack of trying is not clear, but if Mac^R tumour variants prove to be rare, it would provide a ray of hope in the fight against the forces of tumour progression. □

Stellar rotation in Erice

from Evry Schatzman

EVEN stars of the most classical types, if they are rotating, are extremely complicated. The convection zones of any star are difficult enough to understand; nevertheless, the problems facing astrophysicists begin to multiply when the stars are rotating. The generation of a magnetic field, for example, is certainly related to rotation — but how?

The workshop* was restricted to the problems of the instabilities associated with rotation and to the effect of rotation on turbulence. The problem of magnetic fields, which is itself formidable, was purposely limited to a few basic questions concerning its relation to turbulence and rotation. On the other hand, getting hydrodynamicists and astrophysicists together was a good way of finding out which kinds of astrophysical problems can be approached by laboratory experiments, and of determining how far we can go in applying present hydrodynamical knowledge to astrophysical problems.

It is naturally the duty of the astrophysicists to list the problems which seem to depend on processes associated with rotation. In other words, what kinds of observations inform us directly about the physics of the interiors of stars? These observations can be roughly classified according to the depth at which the processes take place, as follows:

(1) magnetic fields in the filaments at the surface of the Sun (perhaps a few scale heights);

(2) supergranulation (the depth of the convective zone);

(3) symmetry properties between the North and South hemispheres of the Sun (flow throughout the whole convective zone);

(4) lithium depletion by transport from the bottom of the convective zone to the lithium burning level (about one scale height below the convective zone);

(5) $^{12}C/^{13}C$ anomalies in giant stars on the first ascending branch of the Hertzsprung-Russell diagram (region in which ^{13}C nuclear processing takes place in main sequence stars, that is, about 1/3 of the stellar radius in from the surface.

In addition, the problem of the origin of white dwarfs' magnetic fields involves the dynamo process in the convective core before large mass loss and white dwarf formation, and consideration of the properties of angular momentum of stars addresses the problem of transfer of angular momentum in the whole star, during formation and on the main sequence.

Only partial answers can be given to these questions. N. Weiss (University of Cambridge) and Galloway (Boulder, Colorado) presented several aspects of the dynamo mechanism, and it is worth stressing that, after years of optimism, the existence of the turbulent dynamo does not seem to be so firmly established. Galloway described the first results of a very large numerical experiment of Gilman (Boulder, Colorado) to simulate the building of the solar-cycle, the significance of which turns out to be very difficult to determine. F. Busse (University of California, Los Angeles) described the role of boundaries on the production of rolls in a rotating thermally unstable region and suggested very strongly that symmetry properties in the solar hemisphere and in the hemispheres of Jupiter can be due to the presence of these rolls.

All the problems of mass transport can be interpreted in terms of meridional circulation or of mixing associated with various instabilities (Rayleigh, shear flow, thermal enhanced). Busse revived the controversy (between Randers, Temesvary, Roxburgh and Baker-Kippenhahn) about the existence of Eddington-Sweet currents by showing that the only stationary solution for a rotating star is a distribution of angular velocities which balances exactly the force induced by stellar oblateness, and cancels the Coriolis force by the suppression of the meridional velocity. S. Temesvary (Tubingen) showed, after Busse, that all non-stationary stream flows decay with the time scale of viscous dissipation, so that the Sun can have any stream flow.

Similarly, for heavier stars (radiative viscosity, electron scattering), the ratio of the viscous dissipation time to the stellar life time grows like M^{-1}! It seems likely that no star lives long enough on the main sequence to reach the magic stationary situation. Therefore, meridional circulation seems to be there. However E. Schatzman (Observatoire de Nice) showed, using Michaud *et al*'s arguments that, if the meridional circulation is responsible for the lithium depletion in the Sun, this contradicts the fact that there is almost no beryllium depletion. J. P. Zahn (Observatoire de Nice) described the conditions for various shear instabilities and Schatzman showed that a consistent picture can be given, with the same turbulent process, probably related to shear flow instability, which explains a variety of abundance peculiarities for elements nuclearly processed deep inside the stars.

The general properties of stellar rotation on the main sequence are now understood, but the detailed mechanisms remain to be established. Then one would not have to rely merely on phenomenology, as one does in discussions of magnetic field generation.

A discussion on the condition in which angular momentum transport takes place in a turbulent flow showed clearly that this problem is still far from being solved. □

Evry Schatzman is at the Observatoire de Nice

*A workshop on rotating stars was held on 2-10 June in Erice.

A hundred years ago

The Americans have stolen a march upon us in sanitary matters, as they have done in so many other things. In March of this year an Act passed the US Congress organising a Board of Health to look after all matters relating to the public health, and to advise Congress what steps should be taken for the promotion of so all-important a matter. We have just received the first number of the weekly *National Board of health Bulletin*, published by this body, who have 50,000 dollars appropriated to them for salaries and expenses. Besides mortality statistics the *Bulletin* contains a number of rules and regulations with respect to the sanitary condition of ships.

Under the date of April 30, a correspondent of the *North China Herald* at Wladivostock, in Russian Manchuria, writes that, although the mountain tops were still covered with snow, the winter had at length come to an end, the ice in the harbour having on that day broken up and floated out to sea. The winter began in October and has been the severest known for many years. The bay was entirely covered with ice from two to three feet thick. Wladivostock is said to be improving, though slowly, and there are signs of an attempt at road-making.

Population biology of infectious diseases: Part I

Roy M. Anderson

Robert M. May
Biology Department, Princeton University, Princeton, New Jersey 08544

If the host population is taken to be a dynamic variable (rather than constant, as conventionally assumed), a wider understanding of the population biology of infectious diseases emerges. In this first part of a two-part article, mathematical models are developed, shown to fit data from laboratory experiments, and used to explore the evolutionary relations among transmission parameters. In the second part of the article, to be published in next week's issue, the models are extended to include indirectly transmitted infections, and the general implications for infectious diseases are considered.

ANY contemporary ecology text contains at least one chapter devoted to predator–prey interactions. The discussion typically embraces field and laboratory observations along with simple mathematical models, and emphasizes how the densities of both prey and predator populations may be regulated by their interaction.

In natural communities, however, an accumulating body of evidence suggests that parasites (broadly defined to include viruses, bacteria, protozoans, helminths and arthropods) are likely to play a part analogous, or at least complementary, to that of predators or resource limitation in constraining the growth of plant and animal populations. Examples from the laboratory are Park's[1] experiments in which the sporozoan parasite *Adelina* drastically reduced the population density of the flour beetle *Tribolium casteneum*, and in certain circumstances reversed the outcome of its competition with *T. confusum*, and Lancinani's[2] studies of the way the ectoparasitic water mite *Hydryphantes tenuabilis* influences the population dynamics of the aquatic insect *Hydrometra myrae*. Various studies have indicated the importance of infectious disease as a mortality factor in populations of wild mammals[3,4], and as possibly the predominant such factor in bird populations[5–7]. For example, among bighorn sheep in North America the main cause of death probably is infection by the lungworms *Protostrongylus stilesi* and *P. rushi*, which then predispose the hosts to pathogens causing pneumonia[8,9]. On a grand scale, Pearsall[10] and others suggest that the geographical distribution of most artiodactyl species in Africa today is largely set by a pandemic of rinderpest that occurred towards the end of the nineteenth century; the numerical simulations of Hilborn and Sinclair[11] confirm that rinderpest can have a big influence on wildebeest population levels. Several authors[3,5,12–20] have argued the general case for infectious diseases as regulators of their host populations.

More broadly, it is likely that interplay between the pathogenicity of viral, bacterial, protozoan or helminth infections and the nutritional state of the host contributes importantly to the density-dependent regulation of natural populations[13], with the parasites greatly amplifying the effects of low levels of nutrition. Such phenomena are largely responsible for the dramatic differences between age-specific survival probabilities for people in developed and underdeveloped countries[21,22]. Indeed, McNeill[23] and others[24,25] have speculated that many of the broader patterns of human history are to be interpreted in terms of the evolving relationships between man and his diseases.

Although there does exist a large and mathematically sophisticated literature dealing with the transmission dynamics of parasitic infections of many kinds, this literature[26–34] almost invariably assumes the host population to have some constant value, and then seeks to answer such questions as: Can the infection be stably maintained in the population? Is it endemic or epidemic? What is the time course (in terms of susceptibles, infectives and recovered individuals) of the infection when introduced into a virgin population? This assumption that the total host population is effectively constant derives from a history of medical interest in human diseases (predominantly in developed countries), where population densities do usually remain roughly constant on the time scale appropriate to the pathology of most diseases. On the other hand, in the ecological and parasitological literature attention has recently been given to the population dynamics of host–parasite associations, with particular emphasis on the way protozoan, helminth and arthropod parasites can depress the natural growth rate of their host populations[13–17,35]. Our review aims to weave together these medical and ecological strands, concentrating on the way parasitic infections can influence the growth rate of their host populations.

The article is being published in two parts. This first part begins with a survey of the diverse array of infectious organisms and of their associated life cycles. We then show how a very simple dynamic model can provide a remarkably detailed explanation of a classic series of experiments on infections in laboratory populations of mice. This success gives the confidence to enable us to proceed into areas less well supported by good data, and we next discuss microparasitic infections with direct life cycles in natural populations; particular attention is given to the evolutionary relations among transmission parameters, the factors which determine the pattern of disease behaviour within populations of hosts and the population consequences of acquired immunity.

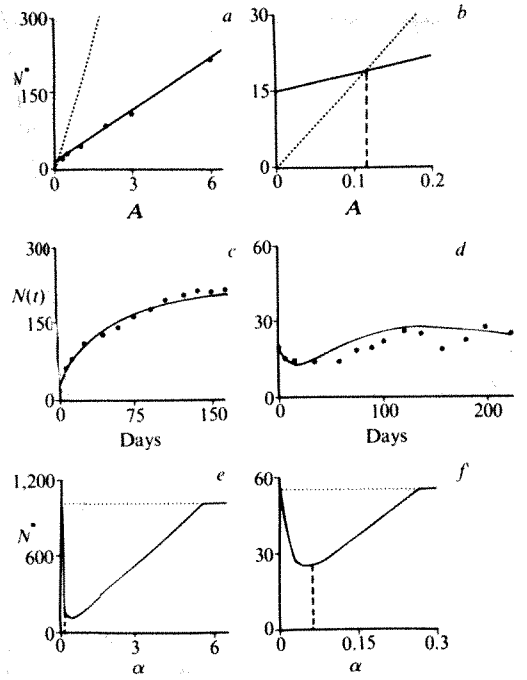

Fig. 1 Population dynamics of *Pasteurella muris* in colonies of laboratory mice. *a*, Relationship between the equilibrium population of mice N^* and the daily rate of input of susceptible mice A (solid dots are observed levels[46,47]; the solid line is the best linear fit, equation (6)). The dashed line shows the estimated relationship between N^* and A in the absence of the disease (the slope is $1/b$, where $b = 0.006$). *b*, An enlargement of that portion of (*a*) where solid anddashed lines intersect, determining the threshold level of immigration A_T, equation (5), below which the disease will not persist. *c*, *d*, Growth of mouse colonies harbouring the disease, from an initial population of 20 mice, for $A = 6.0$ and 0.33, respectively (again, solid dots are the experimental data, and the solid lines are the theoretical predictions described in the text). *e*, *f*, Relationship between the equilibrium population of mice N^* and the disease-induced mortality rate α, as predicted by equations (1)–(3), for $A = 6.0$ and 0.33, respectively. The dotted vertical line shows the actual value of α for *P. muris*.

In the second part of the article[36], we begin with a discussion of macroparasitic infections with direct life cycles in natural populations. Extensions to parasites with indirect life cycles are then briefly indicated, with emphasis on the way the ecology of the general evolutionary trends. Finally, we survey the main mechanisms that can produce cyclic patterns, or multiple stable states, in the levels of infection in the host population.

Diversity of agents causing disease

By using the term 'parasitic infection' to include all organisms—viruses, bacteria, protozoans, helminths and arthropods—on the US Centre of Disease Control's list, we are encompassing a great diversity of life forms and of associated population parameters. Broadly, however, two classes may be distinguished:

Microparasites (viruses, bacteria, protozoans) are characterised by small size, short generation times, extremely high rates of direct reproduction within the host, and a tendency to induce immunity to reinfection in those hosts that survive the initial onslaught[37]. The duration of infection is typically short in relation to the expected lifespan of the host, and therefore is of a transient nature (there are, of course, many exceptions, of which the slow viruses[38] are particularly remarkable).

Macroparasites (parasitic helminths and arthropods) tend to have much longer generation times than microparasites, and direct multiplication within the host is either absent or occurs at a low rate. The immune responses elicited by these metazoans generally depend on the number of parasites present in a given host, and tend to be of relatively short duration[39,40]. Macroparasitic infections therefore tend to be of a persistent nature[13], with hosts being continually reinfected.

Both microparasites and macroparasites may complete their life cycles by passing from one host to the next either directly or indirectly via one or more intermediate host species. Direct transmission may be by contact between hosts (for example, venereal diseases) or by specialised or unspecialised transmission stages of the parasite that are picked up by inhalation (such as common colds), ingestion (such as pinworm) or penetration of the skin (such as hookworm). Indirect transmission can involve biting by vectors (flies, mosquitos, ticks, and others) that serve as intermediate hosts, or penetration by free-living transmission stages that are produced by molluscan or other intermediate hosts. In other cases, the parasite is ingested when an infected intermediate host is eaten by the predatory or scavenging primary host. A special case of direct transmission arises when the infection is conveyed by a parent to its unborn offspring[41] (egg or embryo), as can occur in syphilis and rubella and for many viral infections of arthropods; this process has been termed 'vertical transmission', in contrast to the variety of 'horizontal transmission' processes discussed above.

The natural historian's main concern is often the recondite biological details that make each parasitic infection unique. In contrast, our aim is to understand the basic similarities and differences in terms of: the number of population variables (and consequent equations) needed for a sensible characterisation of the system; the typical relations among the various rate parameters (such as birth, death and recovery rates, transmission coefficients); and the form of the expressions describing the transmission processes. In the absence of such a unified framework, each disease tends to develop its own arcane literature.

Experimental epidemiology: infectious diseases as regulators of laboratory populations of mice

Although there are relatively few studies of the influence of disease upon the dynamics of laboratory populations[1,2,42–45], there is a remarkably detailed body of work of Greenwood *et al.*[46,47], subsequently extended by Fenner[48,49]. These experiments, on laboratory populations of mice infected with various viral and bacterial diseases, have some simplifying features which make them particularly amenable to theoretical analysis. Specifically, the space available to the mice was adjusted to keep the population density constant as absolute levels changed; in addition adult mice were introduced at specified rates, so that the basic process was an immigration–death one (removing the time lags and other complications attendant upon recruiting to the population by natural birth processes). In short, many density-dependent complications are avoided by the design of the experiments.

We now outline a simple model that captures the essentials of these experiments, and discuss its fit to the data for two microparasites: one a bacterium (*Pasteurella muris*); the other a virus (ectromelia, a poxvirus). Both parasites multiply directly within the host and induce a long-lasting immunity to reinfection (mice show some loss of immunity to reinfection by *Pasteurella*, but the immunity to ectromelia seems to be lifelong).

Using notation that will be standard throughout this review, we define the absolute number of susceptible (uninfected), infected and immune mice to be X, Y and Z, respectively. The total number of mice, $N = X + Y + Z$, is not assumed to be some independently-set constant, but is set by the dynamics of the infection. A is defined as the rate at which mice are introduced ($A = 2$ means 2 mice introduced per day), and b the natural mortality rate; in the absence of the disease, the mouse population will equilibrate at around $N^* = A/b$. The infection is a direct one, for which the conventional assumption is that the rate at which mice acquire the infection is proportional to the number of encounters between susceptible and infected mice, being βXY where β is some 'transmission coefficient'. The mortality rate for infected mice is taken to be $b + \alpha$, with α

Table 1 The influence of various types of directly transmitted microparasites on host population growth

Type of disease	Growth characteristic (disease regulates host population if expression is negative)	Threshold host population, for successful introduction of the disease
Horizontal transmission		
No immunity ($\gamma \to \infty$)	$r-\alpha$	$(\alpha+b+v)/\beta$
Life-long immunity ($\gamma = 0$)	$r[1+(v/b)]-\alpha$	$(\alpha+b+v)/\beta$
Transient immunity (duration $1/\gamma$)	$r[1+v/(b+\gamma)]-\alpha$	$(\alpha+b+v)/\beta$
Transient immunity and an incubation (latent) period of duration $1/\sigma$	$r\left[1+\frac{v}{(b+\gamma)}+\frac{(\alpha+b+v)}{\sigma}\right]-\alpha$	$\frac{(\alpha+b+v)(b+\sigma)}{\beta\sigma}$
Transient immunity and disease eliminates reproduction of infected class	$rv/(b+\gamma)-(b+\alpha)$	$(\alpha+b+v)/\beta$
Transient immunity and disease reduces birth rate of infected class to fa	$r\left[\frac{fa-b}{r}+\frac{v}{(b+\gamma)}\right]-\alpha$	$(\alpha+b+v)/\beta$
Vertical (and horizontal) transmission		
Transient immunity and all births from infected class are also infected	$r[1+v/(b+\gamma)]-\alpha$	$(\alpha+b+v-a)/\beta$; threshold is zero if $a>\alpha+b+v$
Transient immunity and a fraction f of births from infected class are also infected	$r[1+v/(b+\gamma)]-\alpha$	$(\alpha+b+v-fa)/\beta$; threshold is zero if $fa>\alpha+b+v$

representing the mortality caused by the disease; there is also a recovery rate v. Recovered mice are initially immune, but this immunity can be lost at a rate γ (for permanent immunity, as for ectromelia, $\gamma = 0$). These assumptions lead to the following equations for the dynamics of the infection:

$$dX/dt = A - bX - \beta XY + \gamma Z \quad (1)$$

$$dY/dt = \beta XY - (b+\alpha+v)Y \quad (2)$$

$$dZ/dt = vY - (\gamma+b)Z \quad (3)$$

Adding all three, the equation for the total population of mice is

$$dN/dt = A - bN - \alpha Y \quad (4)$$

This system of equations (which is similar to that illustrated schematically by Fig. 3) differs from usual epidemiological models in that N is a dynamical variable, rather than some specified constant.

The equations have a stable equilibrium solution with the disease maintained in the population if, and only if,

$$A/b > (\alpha+b+v)/\beta \quad (5)$$

Failing this, the disease dies out, and the population settles to its immigration–death equilibrium value at $N^* = A/b$. If equation (5) is satisfied, the disease persists, and the total population is depressed below this infection-free level to the lower value

$$N^* = \frac{A + D(\alpha+b+v)/\beta}{b+D} \quad (6)$$

Here D is defined for notational convenience as

$$D = \alpha/[1+v/(b+\gamma)] \quad (7)$$

Note that the important threshold phenomena, which enter directly when N is a specified constant[26,31–34,50], appear in a more subtle form when N is itself determined by the dynamics of the disease.

In their experiments on the maintenance of pasteurellosis, *P. muris*, in mouse populations Greenwood *et al.*[45,46] introduced new mice at rates ranging from $A = 0.33$ to $A = 6$ mice per day. The quantities b, α and v can be crudely estimated from life tables for uninfected populations, and from case mortality and recovery rates (we get $b \simeq 0.006$, $\alpha \simeq 0.06$, $v \simeq 0.04$ days^{-1}). Direct estimate of the parameters β and γ is more difficult.

Using data from Greenwood *et al.*[46,47] (and reanalysing to discard the transient initial population values en route to the steady state), we obtain the experimental results shown in Fig. 1*a* for the equilibrium mouse population N^* as a function of A. These data accord well with the linear relation between N^* and A predicted by equation (6). Furthermore, the parameters β and γ may now be roughly estimated from the fit between the theoretical straight line, equation (6), and the data for N^* versus A (we estimate $\beta \simeq 0.0056$, $\gamma \simeq 0.021$ days^{-1}).

In Fig. 1*a*, the dashed line depicts the equilibrium mouse population in the absence of the disease, $N^* = A/b$. The intercept of this line with the linear fit to the data for N^* in the presence of the disease yields the threshold immigration rate, A_T, below which equation (5) is violated and the disease cannot persist; Fig. 1*b* magnifies this aspect of Fig. 1*a*. We estimate $A_T \simeq 0.11$ mice per day (corresponding to an equilibrium population of about 19 mice). Greenwood *et al.* suggested *P. muris* was always maintained in mice populations, but their lowest introduction rate was $A = 0.33$.

With β and γ determined from Fig. 1*a*, we now have a parameter-free prediction of the temporal development of the infection for any initial number of mice $N(0)$ and introduction rate A. Two such fits between theory and data are shown in Figs. 1*c* and 1*d*, for $A = 6$ and $A = 0.33$, respectively. Note the propensity to damped oscillations at relatively small A values. Bearing in mind the complete absence of adjustable parameters, both the fits are extremely encouraging, and strongly suggest that simple deterministic models can be useful even when the host population is small.

How much does the disease depress the mouse population below the level that would pertain in its absence? This general question is answered in Fig. 1*e* and *f*, which shows N^* as a function of disease pathogenicity α, for $A = 6.0$ and $A = 0.33$ respectively. Two significant points emerge.

First, the maximum depression of the host population is achieved by a disease of intermediate pathogenicity[51]. Too small an α has little effect on N^*, while too large an α violates equation (5) and makes it impossible for the disease to persist. The dashed vertical lines in Fig. 1*e* and *f* show the actual value for α for *P. muris*.

Second, note that the higher the immigration rate A, the greater the degree of depression of the host population (relative

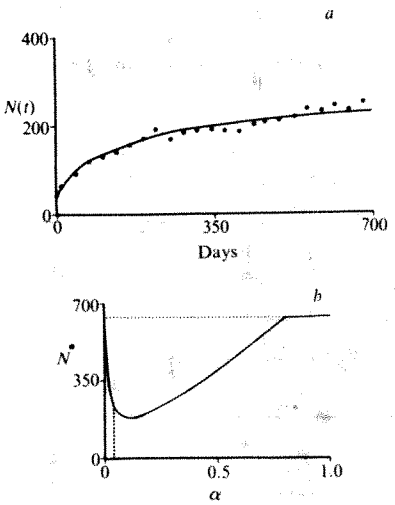

Fig. 2 Population dynamics of ectromelia in colonies of laboratory mice. The data[46,48,49] indicate $b = 0.005$, $\alpha = 0.042$, $\beta = 0.0013$, $v = 0.014$, $\gamma = 0$; the rate of introduction of susceptible mice was always $A = 3$ (all quantities in units of day^{-1}). *a*, Growth of a mouse colony harbouring the disease, from an initial population of 45 mice (dots and solid curve as in Fig. 1*c*, *d*). *b*, Depression of the equilibrium population of mice N^* as a function of pathogenicity α for ectromelia, analogous to Fig. 1*e*, *f*.

to the disease-free equilibrium value). This suggests that diseases caused by microparasites are more likely to persist within, and cause severe reduction of, host populations with high birth (or immigration) rates; this phenomenon derives essentially from the high inflow of susceptibles.

Greenwood *et al.*[46], and later Fenner[48,49], also studied the effects of the mouse pox virus, ectromelia. An analysis, akin to that just outlined, leads to similarly encouraging agreement between our simple theory and the experimental data for ectromelia in laboratory populations of mice. Some of these results are summarised in Fig. 2.

For both *P. muris* and ectromelia, the actual value of the pathogenicity parameter α (indicated by the dashed vertical lines in Figs 1*e*, *f* and 2*b*) lies around the value that induces maximum depression of the host population. Is this coincidence, or does it reflect evolutionary pressures? The question is intriguing, but difficult to pursue in the absence of a larger body of information about a wider range of diseases.

In brief, the theory and the facts of these experiments are in accord in showing how infectious diseases can stably regulate their host populations below disease-free levels. They also show the existence of a critical host density (directly tied to the rate at which new susceptibles are introduced, either artificially in the laboratory, or by births in the natural world), below which the infection cannot be maintained. In this sense, equation (5) replaces the threshold condition of conventional epidemiological models in which the host population is an independently determined constant.

Microparasitic infections as regulators of natural populations

The models discussed above are only half-way to a fully dynamic description of host–parasite interactions. Although the death rates are set by natural processes, and are influenced by the parasites, the 'birth' processes are determined artificially by the rate of introduction of new mice. We now consider what happens when the birth rates are also set by natural processes intrinsic to the host population.

To begin with, we focus on diseases caused by microparasites that are transmitted directly, and ask three main questions: what biological characteristics of an infection determine its impact on host population growth; what are the population consequences of immunological responses; and what conditions lead to endemic or to epidemic infections?

Consider the simple situation of an infection whose transmission processes are as described by equations (1)–(3), except that now the new individuals arise by natural births. This situation is illustrated schematically in Fig. 3. If the *per capita* birth rate is a, independent of whether the individual is susceptible, infected or immune, then the net birth rate term is $a(X+Y+Z)$, and the dynamical system of equations (1)–(3) is replaced by

$$dX/dt = a(X+Y+Z) - bX - \beta XY + \gamma Z \quad (8)$$

$$dY/dt = \beta XY - (\alpha + b + v)Y \quad (9)$$

$$dZ/dt = vY - (b+\gamma)Z \quad (10)$$

The total population of hosts, $N = X+Y+Z$, obeys

$$dN/dt = (a-b)N - \alpha Y \quad (11)$$

Equivalently it is useful to define the intrinsic growth rate $r = a-b$ of the disease-free population and to write $y = Y/N$ as the 'prevalence', or fraction of the host population that are infected. This gives

$$dN/dt = (r - \alpha y)N \quad (12)$$

One of two circumstances now arises. If

$$\alpha > r\left[1 + \frac{v}{b+\gamma}\right] \quad (13)$$

the disease regulates the host population to a stable value N^*. This disease-determined population level is

$$N^* = \frac{\alpha(\alpha+b+v)}{\beta[\alpha - r(1+v/\{b+\gamma\})]} \quad (14)$$

Of this steady population, the fraction infected is given trivially from equation (12) as

$$y^* = r/\alpha \quad (15)$$

Conversely, if equation (13) is not satisfied, the system of equations (8)–(10) eventually settles to a state in which the total population grows exponentially at a rate ρ given by

$$\rho = [B^2 - (b+\gamma)(\alpha - r) + rv]^{1/2} - B \quad (16)$$

with $B = \frac{1}{2}(\alpha + b + v + \gamma - r)$. This population growth rate is necessarily less than the disease-free one, $\rho < r$. Asymptotically, the exponentially growing total population contains a constant number of susceptibles X, with essentially all individuals being infected or immune. The asymptotic prevalence of infection is

$$y \equiv Y/N \to (r-\rho)/\alpha \quad (17)$$

Note the similarities and differences between these conclusions and those for conventional models[26,31–50] in which the total population is set at some constant value. In this crude model there are no density-dependent regulatory effects other than the

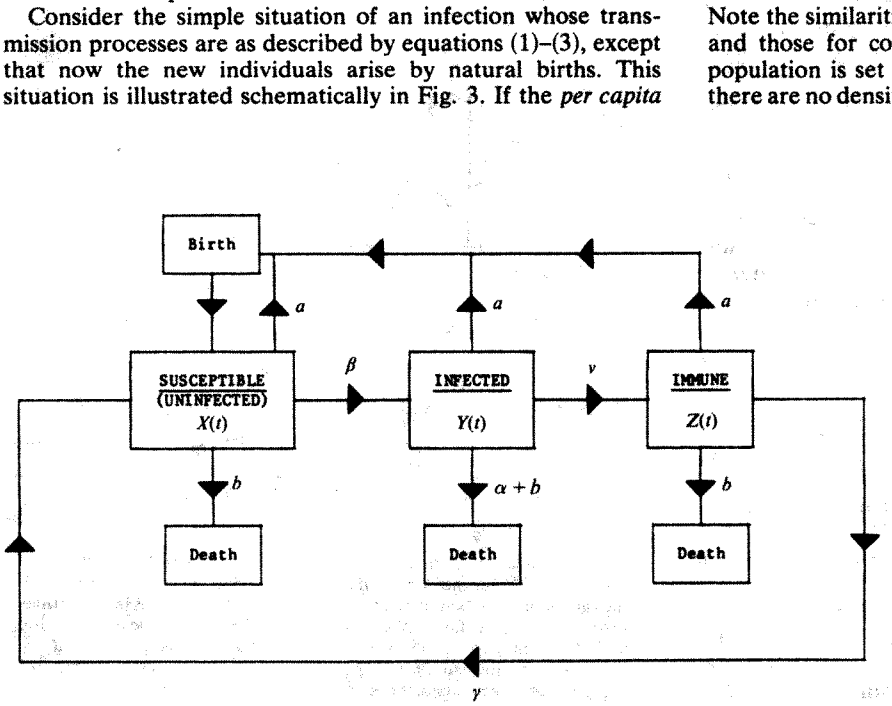

Fig. 3 Diagrammatic flow chart for a directly transmitted infection, described by a compartment model with susceptible (X), infected (Y), and immune (Z) hosts. The flow of individual hosts between compartments is controlled by a set of rate parameters: *per capita* birth rate, a; natural death rate of hosts, b; disease-induced mortality, α, acting on infected hosts; recovery rate, v; transmission rate per encounter between susceptible and infected hosts, β; rate of loss of immunity, γ.

Table 2 Population characteristics of some common directly transmitted microparasites of man (data from refs 66–69)

Parasite	Incubation period (days)	Duration of infectiousness (communicability) (days)	Infectiousness	Duration of immunity	Lifespan of infective stage	Case mortality rate (pathogenicity)	Transmission (H = horizontal V = vertical)
Measles virus	9–12	5–7	High	Lifelong	Very short	Low–high	H
Smallpox virus	12–14	10	Medium	Lifelong	Long	High	H
Rubella virus	17–20	14	Medium	Lifelong	Very short	Low	H, V
Mumps virus	10–20	7	Medium	Lifelong	Short	Low	H
Bordetella pertussis (whooping cough)	7–10	14+	High	Lifelong	Very short	Medium	H
Polio virus	5–20	Long	High	Lifelong	Medium	Medium	H
Varicella zoster virus (chicken pox and shingles)	13–17	20–30	High	Lifelong	Very short	Low	H (V)
Herpes simplex virus	5–8	Long	Medium	Lifelong	Very short	Very low	H, V
Cytomegalovirus	Long?	Long	Medium	Lifelong	Very short	Very low?	H, V
Epstein–Barr virus	10?	Long?	Medium	Lifelong	Very short	Very low?	H
Clostridium tetani (tetanus)	7+	21–30	Low	Lifelong	Long	High	H
Salmonella typhi (typhoid)	10–14	30+	Low	Short	Medium	High	H
Bacillus anthracus (anthrax)	3–7?	?	Low	Long	Very long	Very high	H
Corynebacterium diphtheriae (diptheria)	2–6	20	Medium	Long	Medium	High	H

disease itself and the population 'runs away' (maintaining the disease within it) at the diminished rate ρ if α is too small to satisfy equation (13). Conversely, if equation (13) is fulfilled, the population settles to the value N given by equation (14). In either case, if N is initially less than a threshold value,

$$N_T = (\alpha + b + v)/\beta \qquad (18)$$

then initially Y will decrease and X will increase exponentially at the rate r. However, once X exceeds N_T on this trajectory of exponential increase, then Y will increase, and the system either will converge (steadily or with damped oscillations) on the N^* of equation (14), or will grow at the slower rate ρ of equation (16). Thus the familiar threshold phenomena are found within the more dynamic system of equations (8)–(10).

Equation (13) is clearly a key one. It can be modified to take into account the known biology of a wide range of directly transmitted microparasitic infections. Without discussing the derivations, Table 1 lists the criterion for ability to regulate the host population (generalising equation (13)), and the threshold expression (generalising equation (18)), for a variety of such refinements, including *inter alia* the effects of incubation periods, vertical transmission, and infections that reduce host reproduction.

Several general points emerge from Table 1. (1) For a disease to regulate the host population, the case mortality rate α must be high relative to the intrinsic growth rate r of the disease-free host population. Ability to achieve this degree of regulation is decreased by lasting immunity (γ small) and high rates of recovery from infection (v large, corresponding to infections of short duration). (2) Diseases with long incubation periods, where hosts are infected but not infectious, have less impact on population growth. (3) Diseases which affect the reproductive capacities of infected hosts are more liable to suppress population growth. (4) Vertical transmission lowers the magnitude of the threshold population, N_T needed for successful introduction of the disease; vertical transmission also lowers the equilibrium population of the host in those cases where it is regulated by the disease. (5) The threshold density below which the disease cannot persist within the host population is set by the rate of loss of hosts from the infected class divided by the rate of transmission; high threshold densities are therefore required for the maintenance of diseases with short durations of infection, long incubation periods and high case mortality rates.

Population consequences of immune responses

Although the nature of immunological responses by individual hosts to specific pathogens has received much attention in recent years[37,40,52], relatively little thought has been given to the population consequences of acquired immunity[26,32,53] (sometimes called 'herd immunity' effects). The general insights just culled from equations (13)–(18) can be usefully illuminated by a numerical example. Figure 4*a* shows the growth of a fictitious human population (from an initial size of 50,000) subject to a virus disease and under various assumptions about the duration of immunity. The vital rates and transmission parameter values are as detailed in the figure caption. In more homely terms, they represent a growth rate of the disease-free population of around 3% per annum, a case mortality of about 30% (similar to measles in malnourished human populations with no previous exposure[54]), duration of the infection around 4 weeks, and a transmission coefficient β that implies a threshold population density of $N_T \simeq 380{,}000$ people.

In all cases in Fig. 4*a*, the disease is not maintained and the population grows at its intrinsic 3% rate if it is below the threshold value N_T. Above this point, the population's fate depends on the nature of the immune response. If the duration of the immunity to reinfection ($1/\gamma$) is of short to medium length (less than about 20 yr), the disease is able to regulate the host population at the stable level N^* of equation (14). If the disease induces hardly any immunity (γ large), this equilibrium level N^* will be close to the threshold N_T for maintenance of the disease. Conversely, if the duration of immunity is above 20 yr, the population continues to grow exponentially at some rate lower than 3%; life-long immunity ($\gamma = 0$, as for measles) results asymptotically in 1.6% per annum growth. This example makes plain the important part immunity plays in determining the population consequences of a disease.

The qualitative patterns revealed in Fig. 4*a* are reminiscent of those shown by human population growth[55,56] between the beginning of the Agricultural Revolution (some 10,000 years ago) and the onset of the Industrial-Scientific Revolution (around 300 years ago). In the first 5,000 yr, the global population increased about 20-fold, from around 5 million to around 100 million. The next 5,000 yr saw only a roughly 5-fold increase to around 500 million in the sixteenth century. It may not be unduly fanciful to speculate that the rise of human conglomerations to levels capable of maintaining directly transmitted microparasitic diseases, and the accompanying depression of population growth rates, is at least partly responsible for the observed patterns.

Epidemic and endemic patterns of diseases

Epidemic diseases are characterised by rapid changes in the prevalence of infection. Often such infections disappear from a particular host population for short or long periods. Conversely, endemic infections persist for long times, showing relatively little fluctuation in prevalence. Note that in our dynamic models, equations (8)–(10), the disease always becomes endemic, in the sense that the host population grows to the level $N > N_T$, whereupon the disease is maintained. The prevalence settles to the steady value $y^* = r/\alpha$ if the disease controls the population, and to $y^* \to (r - \rho)/\alpha$ if the population still grows.

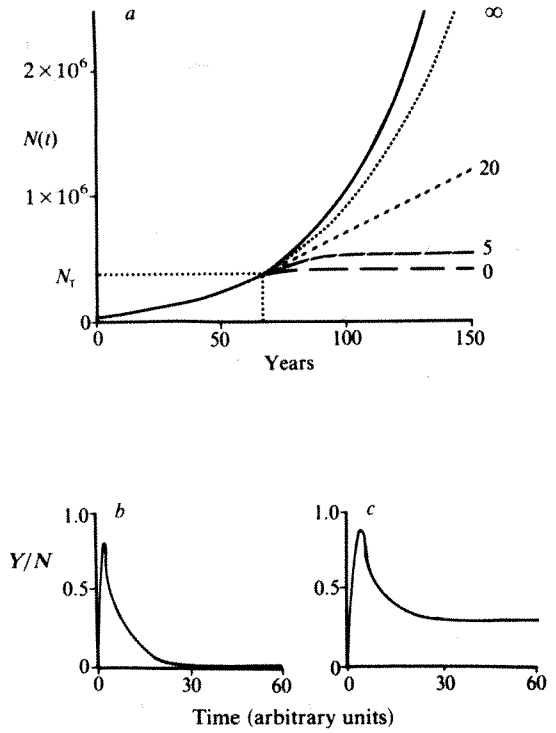

Fig. 4 *a* An illustration of the way the duration of immunity influences the dynamics of host population growth, $N(t)$, for a hypothetical disease; the various population parameters are assumed to be $r=0.03$, $b=0.015$, $v=13.0$, $\alpha=6.0$, $\beta=5\times10^{-5}$ (all per year), and $N(0)=50{,}000$. The solid line depicts the population growth in the absence of the infection. The four broken lines depict the effects of immunity of varying duration, namely (as labelled): $1/\gamma=\infty$ (lifelong); $1/\gamma=20$ yr; $1/\gamma=5$ yr; and $1/\gamma=0$ (no immunity). *b*, Temporal changes in the prevalence of infection, Y/N, following the introduction of the above disease into a virgin population of hosts where the equilibrium prevalence level is low. *c* As for (b), except now the equilibrium prevalence is relatively high.

It is well known, however, that diseases which induce long-lasting immunity often exhibit periodic or episodic 'face out', even within relatively large host populations[26,30,57–61]. In particular, the classic work of Bartlett[62,63] on measles epidemics has suggested the importance of stochastic effects in determining whether a disease will persist endemically or as recurrent epidemics.

Without entering into the detailed complications of a stochastic formulation, we can use the above model to get some qualitative insights about these patterns. Of particular importance is the rate at which new susceptibles appear; hence the general correlation between endemicity and host population size[64], and the observation that the host birth rate is central. Specifically, consider the case where the hosts' intrinsic growth rate is much smaller than the case mortality rate, $r \ll \alpha$. Then, if $N > N_T$, introduction of the infection results in a classical epidemic (see Fig. 4*b*): the prevalence first rises, attains a peak, and then falls to the value given by equation (15) or equation (17), which in either case is very small. That is, if $r \ll \alpha$, it is likely that prevalence settles to be so small as to give a high probability for stochastic 'fade out' and epidemicity. This can be true even for diseases potentially capable of regulating the host population, if r/α and N^* are both sufficiently small. In addition, epidemics can occur even when $r > \alpha$ if the disease does not regulate the host population but merely slows its growth rate slightly, so that $r-\rho \ll \alpha$ (the details of the interplay among parameters that leads to $\alpha+\rho \gg r > \alpha$ are complicated, and can be deduced from equation (16) for ρ). On the other hand, if neither r nor $r-\rho$ is a lot smaller than α, the disease is likely to be endemic, with relatively high values of y^* making stochastic extinction of the disease improbable[62,63,65,66]. This circumstance is depicted in Fig. 4*c*.

Thus infections of short duration which induce lasting immunity will tend to exhibit epidemic patterns. The classic 'epidemic' disease such as measles, rubella and pertussis are of this character[67–70]. As also stressed by Yorke *et al*[32], a broader examination of viral and bacterial infections of man clearly supports this point (see Table 2). Many authors[57,58,71] have observed that such infections are probably diseases of modern societies; in primitive societies the net inflow of susceptibles into small communities was probably too low to maintain the diseases.

Other infectious agents (for example, herpes simplex virus, cytomegalovirus, Epstein–Barr virus) persist in the host for long periods and are of low pathogenicity. Such diseases are usually endemic in character[57] (see Table 2). Moving beyond human populations, it is important to remember that hosts with high rates of reproduction, such as arthropods, may be able to support endemic disease even if host density is low[72]. Furthermore, infectious organisms that induce life-long immunity, or are of high pathogenicity, can be endemic if they produce free-living infective stages which can survive for a long time in the external environment (anthrax bacillus is an example).

There is no doubt that microparasitic infections can slow population growth[73–75]. Whether a given disease will regulate the host population or merely slow its growth, and whether the infection will be endemic or epidemic, depends on the interplay of many biological parameters[32,70]. Unfortunately, our quantitative knowledge of these parameters is limited, even for viral and bacterial diseases of man.

Conclusion

The effects of microparasitic infections on the dynamics of animal populations depend on the ecology of the interactions between host and parasite. These patterns of disease behaviour involve four principal factors, namely: the host providing a habitat for the parasite; the degree to which the parasite induces host mortality (or diminishes the reproductive capability of the host); the extent to which the host acquires immunity; and the necessity of transmission from one host to the next. Overlaid on these factors are many biological complications, specific to individual host–parasite associations, whose sequential action is determined by life cycle structure.

In the second part of this article, we show how a common set of factors are involved in the dynamics of all infectious diseases, whether they are caused by viral or helminth agents, and whether they are transmitted directly or indirectly between hosts.

Possible optical observation of the companion star to the binary pulsar PSR1913+16

Philippe Crane

Bell Laboratories, Murray Hill, New Jersey 07974

Deep R band CCD photographs of the region surrounding the binary pulsar PSR1913+16 have been obtained with the 4-m telescope of the Kitt Peak National Observatory. Using an accurate astrometric solution, we find a star with $M_R = 20.9$ *at the precise coordinates of the pulsar. Possible interpretations of this result, including the unlikely* (<3%) *possibility that it is an accidental superposition of a field star, are discussed. If this object is the physical companion to the pulsar, it is probably a helium star.*

THE discovery of the binary pulsar PSR1913+16[1] has created substantial interest as a system in which various general relativistic effects[2–4] may be measured. The ability to perform these experiments relies critically on two factors: (1) that the pulsar clock should behave in a regular way and (2) that the companion star must be treatable as a point mass. The former point seems to be satisfied[5] so the major remaining issue for tests of relativity to proceed is how to determine the nature of the companion star. Since the optical extinction is probably modest ($A_V = 3.3$; ref. 6) we expect that a non-compact companion should be observable with a sensitive detector on a large telescope. Thus, sensitive observations could establish valuable constraints on the size of the companion star. The small observed apsidal motion in the system already limits the companion star to being either a helium star or a compact object[3].

The observations

We have used the JPL CCD array (400×400 pixels; 0.45″ per pixel) at the prime focus of the 4-m Mayall telescope to observe the region of the binary pulsar PSR1913+16. Our

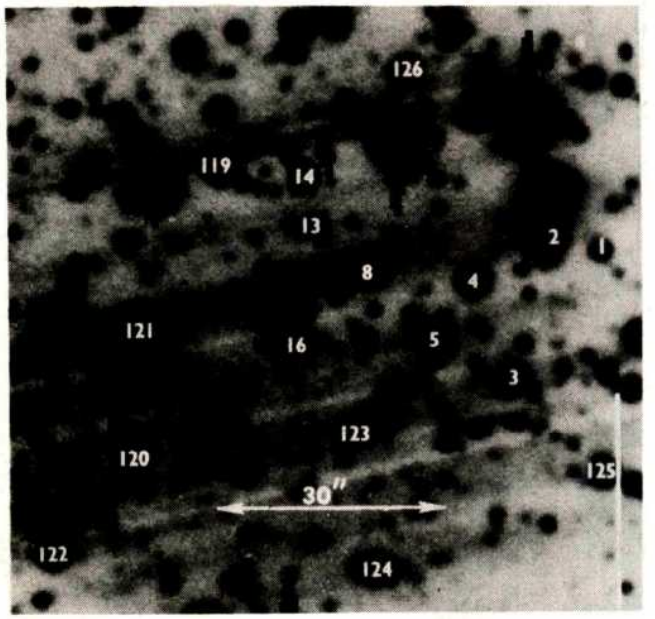

Fig. 1 Finding chart for all the transfer stars on the CCD field (raw data frame). The positions of each star are listed in Table 1. North is up, and east is left. The faint stars 7 and 9 in Fig. 2 are just south of star 8 in this figure.

observational sensitivity would allow us to detect an object with $M_R \leqslant 23.7$. Within our measurement error of 0.32″ we find an object with $M_R = 20.9$ at the precise pulsar radio coordinates given by Taylor *et al.*[7]. This is the same object identified by Kristian and Westphal[8] (also J. Kristian, personal communication) with their positional accuracy of ≃1″.

The region of the pulsar was observed on the nights of 8 and 9 May 1978 and was made with an *R* filter of the system described by Bessel[9]. This passband is a compromise between going as red as possible to reduce the galactic absorption, while avoiding bright variable red OH features in the sky which cause problems with reduction as well as degrade the intrinsic signal-to-noise ratio.

Figure 1 shows a reproduction of a portion of a CCD frame of the area of PSR1913+16. This is a raw data frame and has not been flattened to remove the variations in sensitivity. Also shown are the 17 transfer astrometric stars which were used to determine the position of the very faint objects in the CCD frame. This is one of a set of three 16-min exposures of this field. Figure 2 shows a more detailed reproduction of the CCD frame which has been processed to remove background variations. The faintest objects visible (such as object 22) have $M_R = 23.8$, or are about 3 mag fainter than the limit of Shao and Liller[10].

The astrometric solution has been obtained using the Palomar Sky Survey plates and the SAO star catalogue. This was done on the IPPS and Grant engine at KPNO, and independently at ESO. Our solution differs significantly from that of Shao and Liller[10]. On Kristian's (personal communication) suggestion we performed independent astrometry on copies of the Palomar Sky Survey plates. We put objects 1.6 arc s further east than Shao and Liller[10] and with this solution, we found a star (object 21 in Fig. 2) located within 0.05″ of the pulsar radio coordinates. The radio coordinate uncertainties given by Taylor *et al.*[7] are 0.04″. The positions of 25 objects in the CCD field are listed in Table 1 where the objects numbered <20 correspond to those of Shao and Liller, and the letters correspond to the objects of Kristian *et al.*[11].

We now briefly consider the uncertainties in our stellar position. The Palomar Sky Survey plate was measured and fit with a 6 parameter linear function using 29 SAO stars. The scatter in the fit showed an r.m.s. uncertainty of 0.54″ in each star's position, resulting in an expected r.m.s. uncertainty of 0.11″ for a stellar position determined by this solution. This may be due to SAO star coordinate errors or PSS plate distortion or measurement error. Since the CCD picture contains no SAO stars, secondary astrometric standards are needed to establish the CCD picture coordinates. The SAO coordinate grid was transferred to the CCD picture using 17 stars common to both pictures. These transfer stars are numbered in Fig. 1. This transfer process introduced an estimated error ≤0.1″. The overall coordinate grid error in the CCD picture then becomes 0.15″ r.m.s. The measurement uncertainty of star 21 found experimentally by measuring two CCD frames is ≤0:2″. To check for systematic errors we constructed a coordinate grid using the AGK3 stars and found the errors between the SAO and AGK3 solutions to be 0.2″. Thus we expect the accumulated error (systematic and statistical) of our coordinate solution for star 21 to be ≤0.32″ r.m.s.

Using a standard star (Kopf 27) observed in the *R* band with the CCD detector, we have reduced our measurements to spectrophotometric *R* magnitudes for several stars near the pulsar position. These are also given in Table 1. Our *R* magnitudes are close (±0.2 mag) to the *I* magnitudes given by Shao and Liller[10]. For the candidate star we find $M_R = 20.9$.

Interpretation

Within the tight limits set by the accuracy of the pulsar coordinates and our astrometry, several interpretations of our results are possible: (1) the light seen comes from the pulsar itself; (2) a third star in the system produces the light; (3) a field star accidentally lies along our line of sight; (4) the companion star is the light source. We will now consider these possibilities.

(1) If the light comes from the pulsar, one might expect it to be strongly modulated at the pulsar frequency of 16.9 Hz. However, the observations of Nather *et al.*[12] show the upper limit on optical pulsations is $M_R \simeq 26.2$. This would imply the pulsed fraction of PSR1913+16 must be ≤1%. As the two

Note that stars numbered less than 20 correspond to those of Shao and Liller[10] and letters correspond to Kristian *et al.*[11]. Star 21 is the candidate originally suggested by Kristian and Westphal[8].

* From ref. 7.

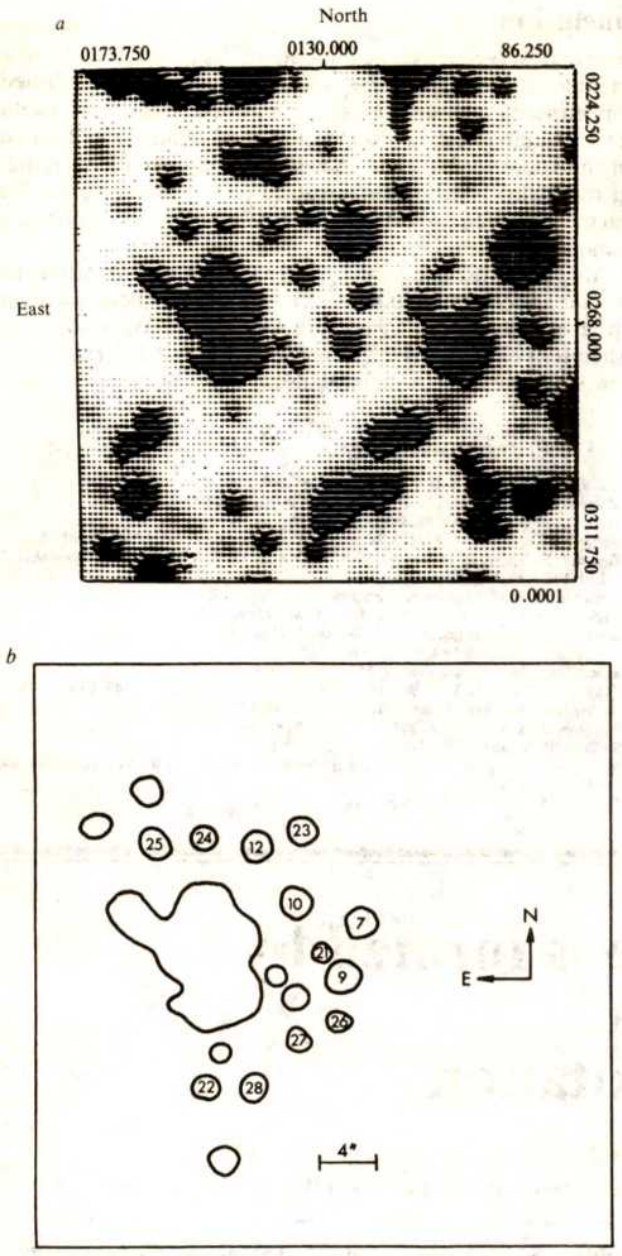

Fig. 2 *a*, Reproduction of the CCD data processed for removal of fixed pattern noise, in the region of the binary pulsar PSR1913+16. Star 21 is the object within 0.05 arc s of the pulsar position. We find a 97% probability that this star is a real association, based on star counts in the field and our measurement uncertainties. Star 22 is the object used as a reference for the limiting magnitude. Other stars correspond to those of Shao and Liller[10]. The positions and magnitudes are listed in Table 1. *b*, Identification chart for faint stars of Table 1 and *a*.

known optical pulsars, the Crab and Vela pulsars[13], show pulsed fractions of ~100% and 50% respectively, this upper limit makes this interpretation unlikely.

(2) If a third star is in the system, it must have survived at least one supernova in the system without being ejected, and must also have produced sufficiently subtle effects on the orbit of the pulsar as to remain undetected until now. This possibility seems extremely unlikely.

(3) To evaluate the possibility that we are seeing a field star, we must consider our measurement uncertainties and the density of field stars. A star would be a valid candidate if that object lay within our error circle 90% of the time. Assuming gaussian errors, this sets the error circle radius as 1.72 $\theta_{\text{r.m.s.}}$,

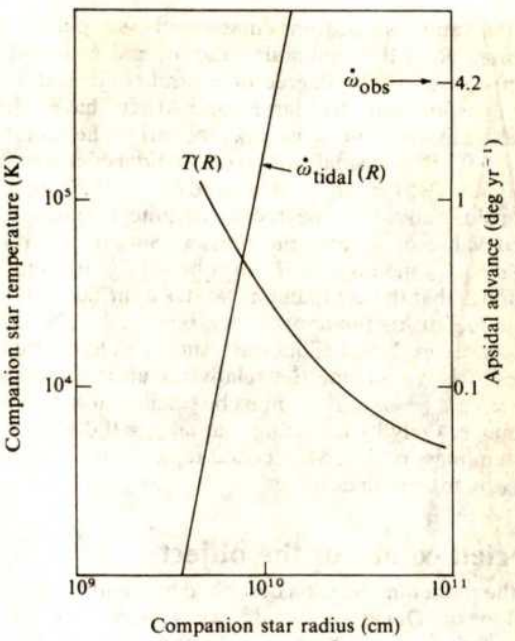

Fig. 3 The relationship between the companion star's radius (bottom scale) and its temperature (left vertical scale) is shown. It is based on our observed flux from the candidate star, an assumed distance and extinction (see text) and the assumption that it radiates as a black body. The apsidal advance (right vertical scale) due to tidal effects is also shown as a function of the companion star radius. The structure of a helium star was assumed (see text). The total observed apsidal advance is also indicated. Simply requiring that the tidal effect be $\leqslant\dot{\omega}_{\text{obs}}$ implies $T_c \geqslant 23{,}000$ K.

where $\theta_{\text{r.m.s.}}$ is the r.m.s. radial uncertainty due to all statistical and systematic effects. In this case, $\theta_{\text{r.m.s.}} \leqslant 0.32''$ so the 90% error circle radius is 0.55". Since our observed coordinate difference is $\leqslant 0.05''$, we (formally) accept the candidate star. Using the CCD picture, we have established the density of stars with $M_R \leqslant 20.9$ at 0.037 stars per arc s^2, so there is a 3% chance that the star is an accidental association and a 97% chance that it is a real association.

(4) The most likely result is that we have detected the companion star of PSR1913+16. The small observed apsidal motion in the system of $\dot{\omega} = 4.24°\ \text{yr}^{-1}$ prohibits hydrogen main sequence stars, since their tidal effects would cause $\dot{\omega} > \dot{\omega}_{\text{obs}}$. Only helium stars and degenerate objects are small enough to be allowed (see ref. 4 and refs therein). We will now estimate some properties of this companion star.

If we assume a distance[1] of 5 kpc and an extinction[6] of $A_V = 3.3$ and further assume the object radiates as a black body, we can establish a relationship between the radius of the object and its temperature using our observed R flux at 0.68 μm of $f_\nu = 1.58 \times 10^{-28}$ erg cm^{-2} s^{-1} Hz^{-1} as shown in Fig. 3. This relation implies unrealistically high temperatures for a compact object. If $r = 10^9$ cm (a typical white dwarf) we find a temperature of 2×10^6 K. If the object is a neutron star ($r = 10^6$ cm) we find $T = 2 \times 10^{12}$ K. Thus, if the object is a thermal radiator, it cannot be degenerate and is expected to be a helium star.

A non-compact companion star will, in general, give a tidal contribution to the apsidal motion of the orbit given by (ref. 3, equation (3.8))

$$\dot{\omega}_{\text{tidal}} = 11.2\left(\frac{k_2}{0.01}\right)\left(\frac{M_p}{M_c}\right)\left(\frac{M_p + M_c}{M_\odot}\right)^{-5/3}\left(\frac{R_c}{0.2R_\odot}\right)^5 \quad \text{deg yr}^{-1}$$

in addition to the general relativistic contribution (ref. 3, equation (3.5))

$$\dot{\omega}_{GR} = 2.11\left(\frac{M_p + M_c}{M_\odot}\right)^{2/3} \quad \text{deg yr}^{-1}$$

where M_p and M_c are the masses of the pulsar and its companion, R_c is the companion radius, and k_2 is a structure function measuring the degree of central condensation of the companion star. Roberts, Masters and Arnett[4] have calculated, using stellar models, the value of k_2 for various helium stars and find $k_2 \simeq 0.05$. The apsidal motion due to tidal effects is shown in Fig. 3, assuming $M_p = M_c = 1.4 M_\odot$ and $k_2 = 0.05$. Note that for a given apsidal advance, the radius is quite insensitive to the assumed value of k_2 and the masses. Simply requiring that $\dot{\omega}_{tidal} \leq \dot{\omega}_{observed}$ means that R_c must be $\leq 1.2 \times 10^{10}$ cm. This in turn implies that the companion star has a surface temperature $T \geq 23{,}000$ K using the above black-body result. Note that, at least for more massive helium stars, such high temperatures are expected[14]. If we include the relativistic apsidal motion then, $\dot{\omega}_{tidal} = \dot{\omega}_{observed} - \dot{\omega}_{GR}$, so R_c must be smaller, and T larger than given above. Only by assuming that $\dot{\omega}_{tidal} = 0$ does one obtain the system mass of $2.85 M_\odot$ needed to account entirely for the $\dot{\omega}_{observed}$ by the relatistic effect.

Expected colour of the object

Using the reddening relation described by Nandy *et al.*[15] and the extinction of Davidsen *et al.*[6] we expect $E(V-R) \simeq 1.0$. Johnson[16] gives $V-R$ for stars in the above temperature region of $\simeq -0.1$. To convert our spectrophotometric magnitude to a Johnson R magnitude we must add -0.2. We thus roughly expect $V \simeq 21.6$. Kristian and Westphal[8] reported $V = 22.5$. If the given V and R are correct and the object is the companion star, this result suggests that the extinction is greater than that assumed and the temperature of the companion star is hotter.

Conclusion

We have observed a likely candidate (97% probability) for the companion star of PSR1913+16. This result could be confirmed by spectroscopic observations. If confirmed, this system might not be a suitable testing ground of general relativity and would bring into question the claimed evidence for gravitational radiation by Taylor *et al.*[7]. The existence of a helium star for the binary companion would also be interesting on evolutionary grounds.

A κ-immunoglobulin gene is formed by site-specific recombination without further somatic mutation

J. G. Seidman, Edward E. Max & Philip Leder

Lab. of Molecular Genetics, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland 20205

The active gene for a κ light chain is formed by a somatic recombination event that joins one of several hundred variable region genes to one of a series of recombination sites (J-segments) encoded close to the κ constant region gene. The nucleotide sequences of cloned germ line and somatically recombined genes define the precise organisation of these genetic segments and the site and nature of the recombination event that joined them. Apart from somatic recombination, no further alteration of the germ line sequence has occurred. The J-segment is of special interest as it encodes signals for both DNA and RNA splicing and provides a means of generating further immunoglobulin gene diversity.

A COMPLETE explanation of antibody gene expression must take into account at least four criticaLobservations—the striking variable/constant structure of antibody molecules, the diversity of their sequences, the fact that only one member of an allelic pair of antibody genes is expressed in a given lymphocyte, and the curious process by which a given lymphocyte seems to be able to sequentially associate a single variable region with two or more different classes of heavy chain constant regions (see complete bibliography in ref. 1). The argument advanced by Dreyer and Bennett[2], namely, that variable and constant regions are separately encoded in the germ line and are probably drawn together by somatic recombination, is likely to be relevant to each of these features of antibody gene expression.

Most recently, a series of experiments involving the analysis of DNA fragments encoding variable and constant region immunoglobulin genes has convincingly borne out the predictions of the Dreyer–Bennett hypothesis[3–5]. In particular, an examination of cloned DNA fragments has added considerable and unexpected detail to our understanding of the arrangement of genes corresponding to immunoglobulin λ and κ light chains[1,6–9]. Our own experiments have concerned the κ light chain genes of the mouse[1,4,8]. (Antibody diversity in the mouse depends almost entirely on κ, as opposed to λ, light chains[10].) By cloning individual genes and using *in situ* hybridisation of DNA restriction fragments, we have shown that a large repertoire of κ variable region genes is encoded in the germ line genome. Saturation hybridisation experiments by Valbuena *et al.*[11] support this view. In addition, those genes that we have sequenced seem to be foreshortened, that is, they fall 13 amino acid codons short of the conventionally defined variable region sequence[4]. In the case of the MOPC-41 κ chain, we were able to show that formation of the active gene involved a recombination event that joined such a foreshortened variable region gene to a segment of DNA (called the J or joining segment) encoding

0028–0836/79/310370—06$01.00

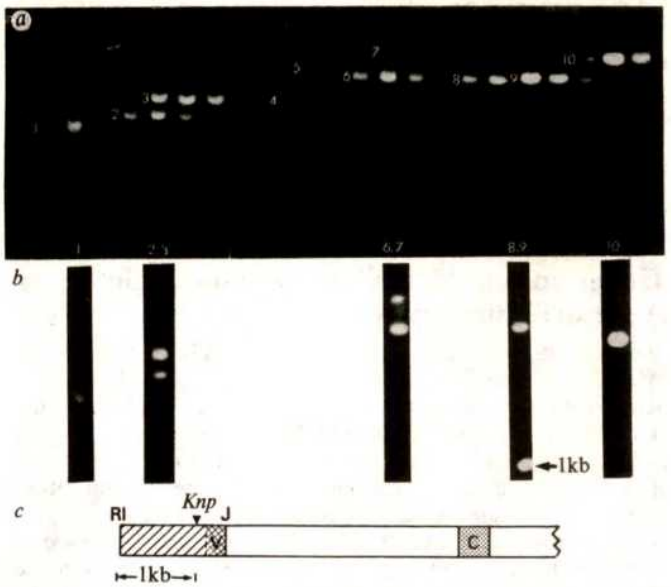

Fig. 1 Identification of the *Eco*RI fragment of embryonic DNA that contains the germ line MOPC-41 variable region gene. *a*, *Eco*RI-digested embryonic DNA was fractionated first by RPC-5 column chromatography and then by agarose gel electrophoresis, transferred to a nitrocellulose filter and hybridised to the ^{32}P-labelled 1 kilobase *Eco*RI-*Kpn*I (see map, bottom panel) fragment from the recombined gene as described previously[1,8]. *b*, Separate fractions from the RPC-5 column containing MOPC-41-like variable-region sequences were pooled as indicated, cleaved with *Kpn*I, fractionated on agarose gels, similarly transferred to nitrocellulose filters and hybridised to the ^{32}P-labelled *Eco*RI-*Kpn*I fragment. *c*, Location of the sequence within the MOPC-41 recombined gene (the *Eco*RI-*Kpn*I fragment) that was used as probe to detect the germ line gene.

these last variable region sequences[8]. Even in the active form, however, the fused V/J segment was separated from the constant region gene by a 3.7 kilobase intervening sequence. Bernard *et al.*[6] have shown that analogous mechanisms are involved in rearrangement of λ light chain genes, although there may be only one variable region gene for each of the two λ classes.

But many important questions remain. Does the germ line gene undergo substantial somatic mutation before expression? Can recombination between variable and J-segment serve to generate additional diversity? What is the structure of an active, as opposed to an inactive or germ line, immunoglobulin gene? Which sequences define the boundaries of the coding and other functional domains of the gene? And finally, what can these observations tell us about allelic exclusion and/or heavy chain switching?

We have attempted to answer some of these questions by cloning and determining the sequence of major portions of an active κ gene and its germ line precursors. In its germ line form, this sequence is encoded in at least four discrete segments of DNA. A somatic recombination event joins two of these segments, creating the expressed gene which then consists of three discontinuous coding segments. This recombination occurs between one of many germ line variable region genes and one of five short joining regions that we find close to the κ constant region gene[18]. The adjoining or J-region is especially interesting in that it must encode two specialised recombination sites, one for DNA joining and another for RNA splicing. Apart from this recombination event, the sequence of the expressed variable region gene is identical to the germ line sequence, that is, no somatic mutation has occurred. A comparison of these sequences with other κ and λ genes suggests that this general structure and mechanism have been preserved in evolution. Further, it suggests that antibody diversity arises principally from three sources: a large and diverse germ line repertoire of

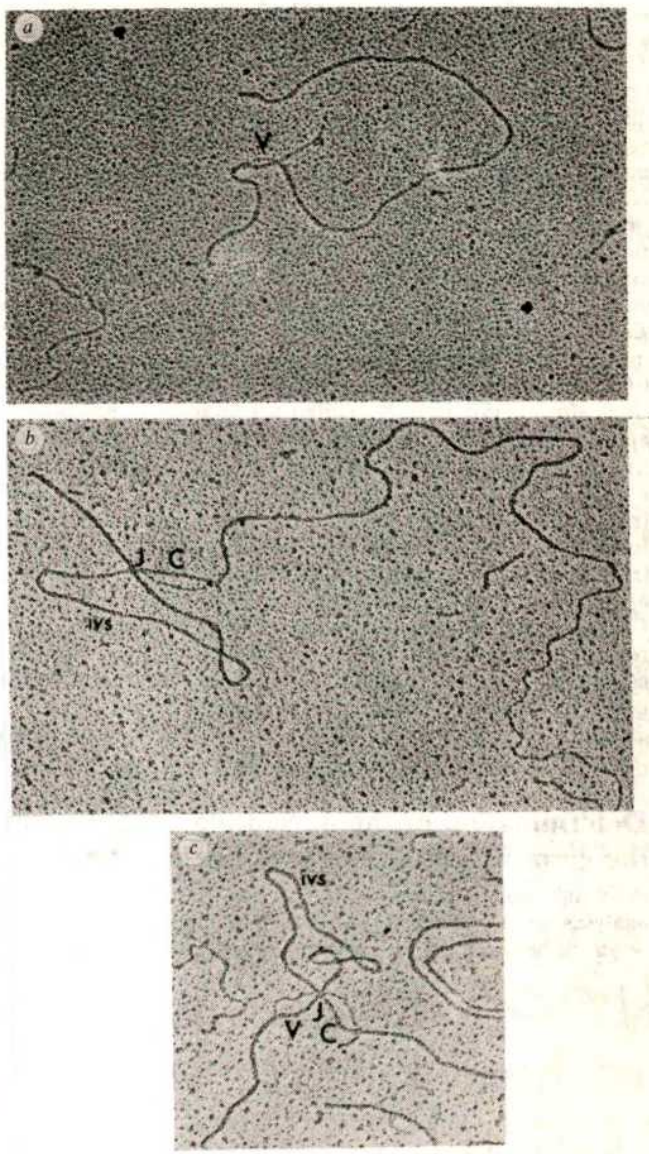

Fig. 2 R-loops formed between MOPC-41 light chain mRNA and the cloned germ line and recombined MOPC-41 light chain genes. Panels represent R-loops formed between MOPC-41 mRNA and the following: *a*, MOPC-41 variable region fragment derived from embryonic DNA (6.8 kilobases); *b*, constant and J region fragment derived from embryonic DNA (16 kilobases); and *c*, fragment derived from MOPC-41 DNA (16.5 kilobases) that contains recombined variable and constant region genes[8]. The R-loops corresponding to the variable region (V), J region (J) and constant region (C) are indicated. IVS identifies the 3.7 kilobase intervening sequence between J region and C region. At least 20 molecules of each type were measured to determine the distances of the genes from one another, and from the ends of the fragments. The R-loops shown in panels *b* and *c* have been published previously[8] and are shown for comparison. The methods of R-loop formation and characterisation have been described previously[4]. The structures were confirmed by direct sequence determination (see Fig. 4).

variable region genes, a smaller set of J-regions, and a recombination mechanism that joins these sequences in different combinations in the somatic cell.

Cloning the germ line precursor of the active MOPC-41 κ chain gene

The complete MOPC-41 κ chain gene is formed by a recombination event that joins the germ line variable region sequence to a J-region segment located about 3.7 kilobases from the κ constant region gene[8]. We have previously cloned the germ line J and constant region genes on a single segment of embryonic

DNA. We have also cloned the recombined MOPC-41 gene on a segment of DNA derived from a MOPC-41 plasmacytoma[8]. These clones constitute the product, but only one of the two precursors involved in the formation of the light chain gene. A difficulty arose in cloning the remaining germ line precursor, the variable region gene. It—like other κ variable region genes—is a member of a small set of approximately 10 closely related genes, all of which cross-hybridise to a MOPC-41 variable region probe[1]. Fortunately, the parental fragment could be distinguished from the other related sequences by restriction endonuclease digestion (Fig. 1). The recombinant clone had a characteristic *Kpn*I site which occurred 1 kilobase from the *Eco*RI site at the 5′ end of the variable region sequence. Only one of the ten hybridising *Eco*RI fragments of embryonic DNA (that were separated by two-dimensional analysis[1] and detected by *in situ* hybridisation[12]) yielded a 1 kilobase fragment after appropriate digestion. The fragment (no. 8 in Fig. 1) was tentatively identified as the parental variable region gene.

The partially purified fragment was cloned in λgtWES·λB (ref. 13) and analysed by visualisation of R-loop structures formed by annealing MOPC-41 κ chain mRNA to the cloned fragment (Fig. 2). A single variable region R-loop was visualised approximately 1 kilobase from the 5′ end of the fragment. R-loop structures formed between the germ line J/constant region fragment and the active, recombined gene are shown for comparison (Fig. 2). The separate variable and constant region genes, on separate *Eco*RI DNA fragments in the germ line (Fig. 2*a* and *b*) are recombined so as to reside on the same DNA fragment in the antibody producing cell (Fig. 2*c*).

Determination of the nucleotide sequences of the germ line and rearranged genes

Although our electronmicroscopic and restriction enzyme analyses were consistent with a recombination event having occurred between the two parental genes, the fine structure of the precursor genes and their recombination product as well as the nature of somatic changes, if any, that accompanied the recombination event could only be shown by direct sequence determination. The procedure used in determining the sequence was the partial chemical degradation method of Maxam and Gilbert[14]. The restriction enzyme strategy, the overlapping sequences determined and the extent of bi-directional sequencing are shown in Fig. 3. The sequences determined are shown in Fig. 4.

The germ line MOPC-41 variable region gene: evolutionary conservation

Inasmuch as the amino acid sequence of both the mature MOPC-41 protein[15] and its hydrophobic leader[16] have been determined, the coding sequence is easily identified within the cloned fragment. The germ line MOPC-41 variable region gene (VK41) is arranged in a fashion analogous to that of the mouse germ line λI and λII variable region genes[6,9] and other sequenced germ line κ variable region genes (VK2 and VK3)[4]. An 18 amino acid hydrophobic leader coding sequence is separated by a 129 base-pair intervening sequence from the main variable region coding block. [We do not believe that the in-phase initiation codon present close to the analogue of codon −4 in K2 and K3 is the true initiation codon[4]. Rather, further sequencing has revealed that the VK2 gene also has a separately encoded hydrophobic leader sequence (Y. Nishioka, unpublished).] The coding sequence resumes at coding position −4 of the leader sequence and continues to position 95 in the variable region. As we have shown for other germ line κ variable region genes[4], the last 13 amino acid codons commonly associated with the variable region are missing. Thus, the general structure of these genes seems to have been strongly conserved in the hundred or so million years that κ and λ sequences have undergone separate evolutionary development. It is also worth noting that the sequence homologies, both between other λ and

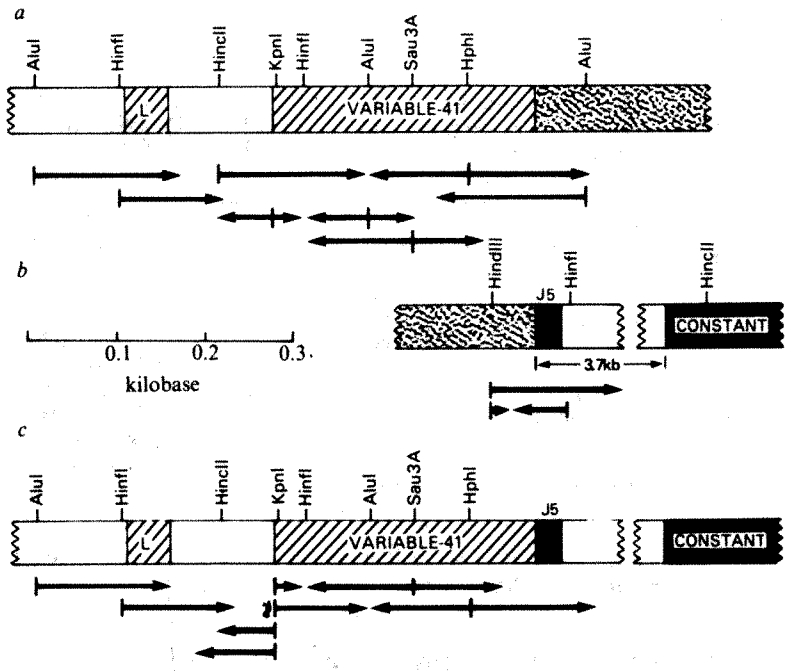

Fig. 3 The strategy used to determine the nucleotide sequences of cloned immunoglobulin genes. The basic approach and methodology have been described by Maxam and Gilbert[14]. Our application of their technique has also been described previously[8]. The 6.8 kilobase fragment containing the germ line MOPC-41 variable region gene[6,8], the 6.5 kilobase *Bam*HI-*Eco*RI fragment of the 16 kilobase *Eco*RI fragment carrying the germ line J and constant region genes[8], and the 7 kilobase *Bam*HI-*Eco*RI fragment of the 16.5 kilobase fragment carrying the recombined gene[8] were re-cloned in the bacterial plasmid pBR322. Restriction fragments between 500 and 2,400 base pairs were excised from these plasmids by cutting with the enzymes *Eco*RI, *Kpn*I, *Xba*I, *Hin*dIII and *Bam*HI. (The *Eco*RI site is 1.2 kilobases to the 5′ side of the variable region and recombined genes.) *Xba*I cleaved the embryonic derived fragment 300 base pairs to the 3′ side of the variable region gene and 1.2 kilobases to the 3′ side of the recombined gene. *Hin*dIII cleaved the constant region fragment gene containing fragments between J1 and the constant region gene. *Bam*HI cleaved 1 kilobase to the 3′ side of the constant region gene (ref. 8 and our unpublished results). These fragments were cleaved with the indicated enzymes and end-labelled with ^{32}P by the action of T4 polynucleotide kinase; finally a smaller fragment labelled at only one end was obtained by re-cleaving the labelled fragments with a third restriction enzyme. The labelled fragments were isolated from polyacrylamide gels and subjected to base-specific chemical degradation and subsequent fractionation on polyacrylamide–urea gels. The derived sequences are indicated in Fig. 4. The accuracy of any sequence is probably greater than 95%; sequences which have been determined in both directions are more accurate than sequences which have been determined in only one direction. The structural gene sequences have been indicated by diagonal lines (leader and variable region) and solid lines (J and constant region genes). The portions of the fragments that are removed by the recombination event are indicated by stippled regions. The clear portion of the fragments are sequences which become the 5′ flanking and intervening sequences of the recombined gene. The scale shows the distance represented by 0.5 kilobase on the cloned fragment.

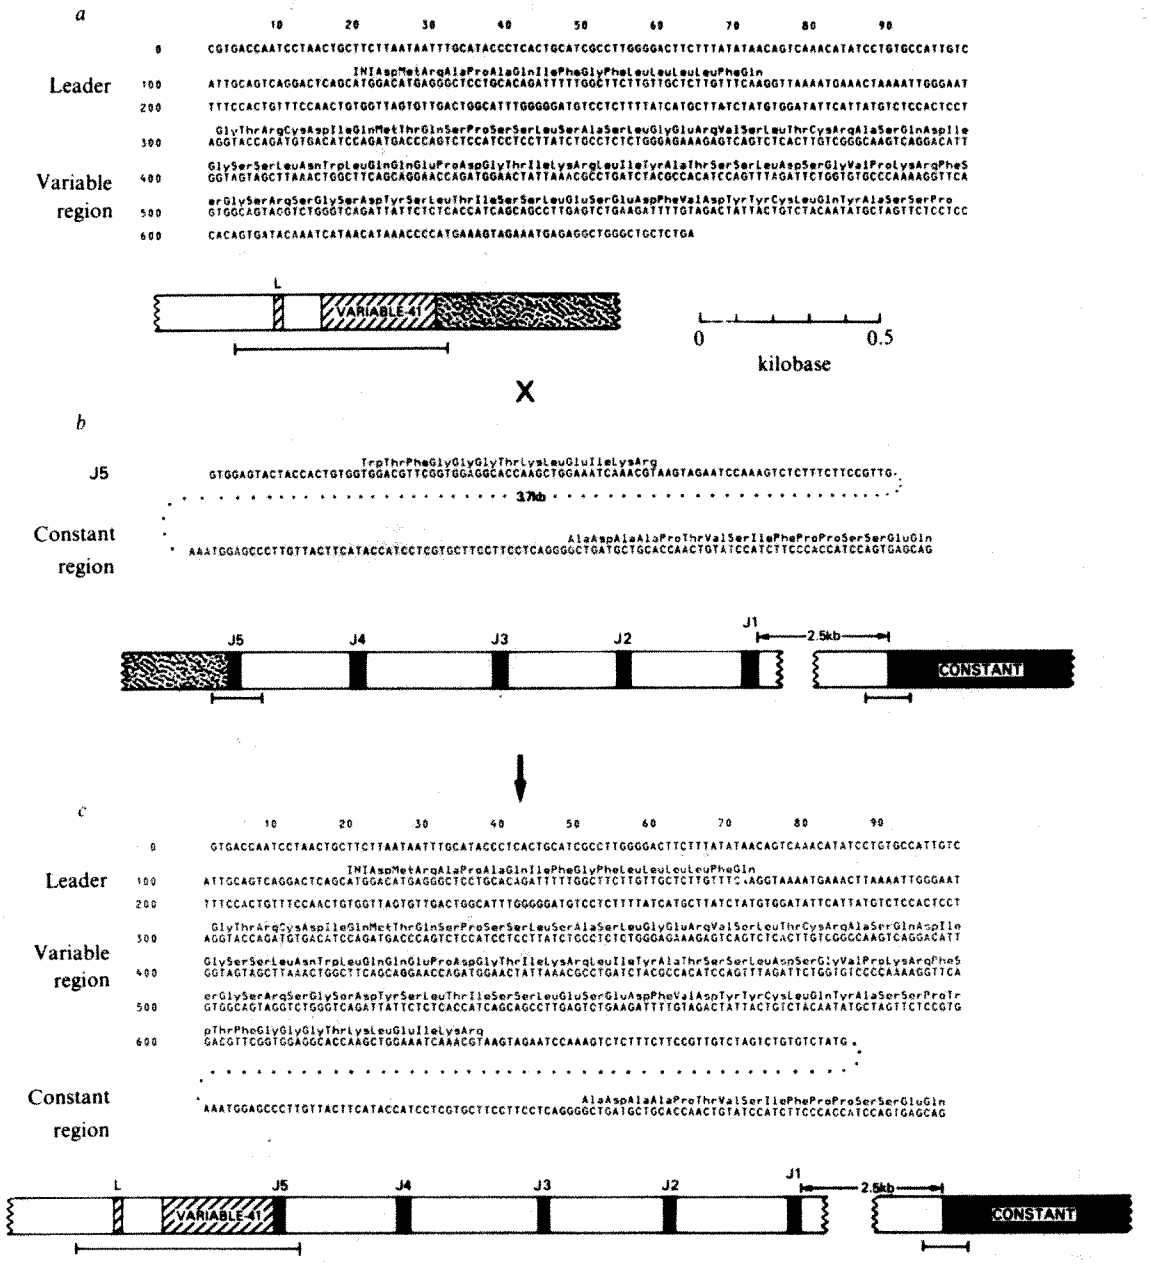

Fig. 4 Nucleotide sequences of the germ line and expressed genes encoding the MOPC-41 light chain. *a*, Germ line leader and variable region gene; *b*, germ line J region and constant region genes (the leader/variable gene and the J/constant gene are encoded on separate *Eco*RI fragments cloned from embryonic DNA); *c*, recombined gene: the light chain gene expressed in the MOPC-41 cell has been formed by fusing the germ line variable and J region genes. Gene segments are diagrammatically coded as described in Fig. 3. The location of each sequence with respect to the structural gene sequence is indicated on the figure below each sequence. The locations of four additional J-region genes, J4, J3, J2 and J1 in the intervening sequence were determined by Max *et al.*[18] using nucleotide sequence analysis.

other κ genes, are most strongly preserved in the coding sequences (85%, VK41/VK2) and least well in the intervening sequences (25%, VK41/VK2), a pattern which was noted originally between closely related β globin genes[12].

The recombination event and the J region: homologies and inverted repeats

As regards the premature termination of the germ line MOPC-41 variable region gene at codon 95, our electronmicroscopic R-loop analysis (Fig. 2) suggests that the remaining codons occurred at a region 3.7 kilobases from the germ line constant region gene. In fact, direct sequence analysis confirmed that the J coding sequence occurs in this region, extending from codon 96 (Trp-TGG) to 108 (Arg-CGT). The precise point at which the recombination event occurred can also be specified by comparing the sequences of the germ line genes to that of the recombined gene (Fig. 5). The codon in position 95 (Pro-CCT) of the germ line variable region gene has been converted to a different proline codon (CCG) by the recombination event. The G in the third position is therefore derived from the J-region fragment. Obviously a shift of the recombination site would create a different codon and this could be a source of additional immunoglobulin diversity (see below and ref. 18).

The nature of all recombination events between V and J regions cannot be confidently inferred from the single recombination event analysed here. However, our further sequence studies located at least four additional and different potential J sequences between the germ line MOPC-41 J and the constant region gene[18]. These sequences occur at regular intervals about 320–360 nucleotides apart and are indicated in the map shown in Fig. 4. Clearly, if all combinations are permitted, considerable diversity can be generated by simply combining the multiple variable region germ line genes with these J segments. This

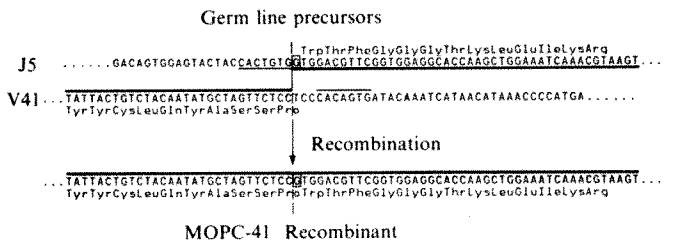

Fig. 5 Nucleotide sequences involved in the recombination of germline precursors of the active MOPC-41 gene. The precise location of the recombination event is indicated by the cross-over line. The amino acid sequences encoded by each segment are indicated. The locations of a 7 base pair sequence to the 5′ side of the J region and a homologous 7 base pair sequence to the 3′ side of the variable region are underlined. The sequence is also an inverted repeat; that is, the V region segment is complementary to the J-region segment. Notice that the recombination event occurs in the middle of a proline codon, generating a new proline codon.

possibility has been suggested by a comparison of amino acid sequences of κ light chains in two inbred strains of mice[19,20]. Diversity would be even more greatly amplified if the recombination event could use different splicing frames at each V/J junction[18].

A comparison of the MOPC-41 variable and J sequences indicates that the recombination event does not depend on simple generalised recombination such as that which requires extensive, in-phase sequence homology. There are several short regions of homology in the variable and J-region, but none align the two sequences in phase. Perhaps one of the most attractive of these homologies is a seven base sequence CAC($\frac{T}{A}$)GTG which occurs immediately adjacent to the splice site in both variable and J regions (see underlined sequences, Fig. 5). The sequences are short palindromes or inverted repeat sequences and interestingly appear to border all variable and J regions thus far sequenced[18]. Because these are inverted repeats, they are mutually complementary and can be drawn as a short stem structure between V and J genes. We have considered the implication of this possibility and specific molecular mechanisms for recombination in detail elsewhere[18].

It is also likely to be significant that the J-region structure has been closely preserved between κ and λ genes. We have compared our κ J-region sequence to that determined for the λ (type I) J by Bernard *et al.*[6] (Fig. 6) and find that not only are they identical in length but they are also closely homologous in sequence. In fact, the homologous inverted repeat sequence referred to above is largely preserved adjacent to the recombination site in both the λ J and variable region genes (Fig. 6). It is simplest—perhaps too simple—to think of such sites as recognition core sequences for specialised, site-specific recombination. Nevertheless, these small inverted repeats are formally analogous to the inverted repeats seen at the ends of bacterial insertion sequences[21,22].

Except for recombination, the germ line variable region sequence is unaltered in the active gene

Whereas one of a large number of germ line κ variable region genes recombining with one of several J-segments might suffice to generate the complete κ chain repertoire, studies of λ light chains strongly suggest that point mutations arise somatically, producing additional diversity[23]. Sequence determination of λ light chain genes[6] supports the notion that simple somatic base alterations are responsible for the amino acid differences noted among λ chains. Still, even in the λ chain system, a predominant sequence ascribed to the unaltered germ line gene was seen in about two-thirds of the chains examined[23]. Although the single position changes noted in myeloma proteins would increase the light chain repertoire and might be relevant to the immune response (they might also be irrelevant, the result of a transcriptionally active gene being repeatedly replicated during prolonged passage in a tumour), the germ line sequence remains the major λ sequence expressed.

Such protein sequence comparisons have been much more difficult in the mouse κ system, for—in contrast to the λ light chains—mouse κ light chains are extremely diverse in sequence, a fact that is consistent with their role as the major (>95%) light chain in all mouse antibodies. This diversity is further consistent with a large number of germ line variable region genes[1,6,11]. It was therefore of particular interest to determine whether additional somatic mutations had occurred in the germ line VK41 gene. A comparison of the germ line and expressed sequences (Fig. 4) indicates that—with the exception of the V/J recombination event—they are identical in every position. The expressed gene has, therefore, undergone no further somatic alteration.

The recombined MOPC-41 gene remains an interrupted gene: intervening sequences

The large intervening sequence (IVS-2) that separates the recombined variable-J sequence from the constant region gene in MOPC-41 DNA was first identified by visualising R-loop structures formed between the gene and its mRNA (ref. 8). Both this sequence and the smaller intervening sequence (IVS-1) that separates the major portion of the leader from the variable region and are strictly analogous to the corresponding structures of the λ light chain gene[6,7]. Their borders are established by our nucleotide sequence analysis and these seem to occur within codon −4 and within codon 108 for the small and large intervening sequences, respectively (Fig. 4). Evidence from the mouse globin system[25–27], the ovalbumin system[28,29] as well as the immunoglobulin system[30–32], indicates that these intervening sequences are transcribed and spliced out during maturation of a large mRNA precursor. The nature of the RNA splice signal is not yet known, as there is limited conservation of sequence between these sites among different genes. However, as a general rule, the data are consistent with the elimination of

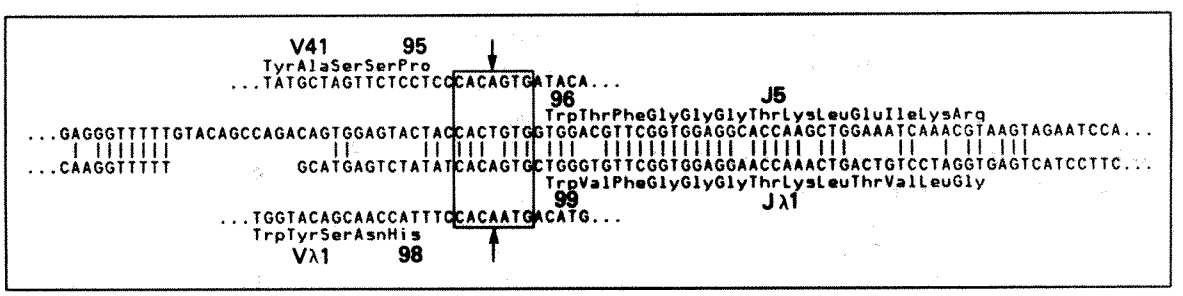

Fig. 6 Nucleotide sequence homologies between κ and λ variable and J-region genes surrounding the DNA recombination site. J1 and Jλ1 have been aligned to indicate the close relationship between these two DNA sequences (homologies are indicated by vertical lines). The 3′ ends of the κ (MOPC-41) and λ I variable region genes are indicated so that the location of the common sequence, CAC($\frac{A}{T}$)GTG, is aligned (boxed sequence). The arrows indicate the centre of this small palindrome that constitutes an inverted repeat noted in Fig. 5 and present in both κ and λ variable and J-region genes. The λ gene sequences are from Bernard *et al.*[6].

sequence beginning with [GT] and ending with [AG] (ref. 28). The sequence of the κ light chain gene is consistent with this rule as follows:

IVS-1, CAA G(GT . . . AG)GT ACC,

IVS-2, AAA C(GT . . . AG)GG GCT

where the underlined sequences represent codons and the sequences within parentheses, excised segments.

Antibody diversity, allelic exclusion and the heavy chain switch

We have discussed the role that recombination might play in creating antibody diversity—joining one of hundreds of variable regions to one of several J-segments, each of which is linked, in turn, to the single constant region gene[18]. It is clear that this recombination event is critically linked to antibody gene expression. If recombination occurs (or occurs properly) on only one of a pair of alleles, presumably only the recombined gene will be expressed. Allelic exclusion may therefore be a consequence of a single authentic recombination event affecting only one member of a chromosome pair[8]. Preliminary evidence suggests that germ line genes and/or aberrant recombinants occur together with active genes in myeloma tumours[8,33].

The problem of moving a single heavy chain variable region from one heavy chain constant region to another—the so-called heavy chain switch—may also involve the use of a J-like segment and a site-specific recombination event. However, the need to distinguish a stable recombinant (as in a light chain gene) from an unstable one (as in a μ chain gene) suggests that two independent rearrangements are involved in switching from a μ to a γ or an α chain. The first is probably analogous to what we see in the light chain gene, but the second might be quite different, involving an alternative mechanism of DNA rearrangement.

We thank Dr Michael Potter for providing the original myeloma tumours used in these studies. We also thank Barbara Norman and Marion Nau for their help with the biochemical aspects of these studies, Margery Sullivan for help with electron microscopy and Terri Broderick for preparation and editing of the manuscript.

Persistent emission from X-ray burst sources and the nature of galactic bulge X-ray sources

TWO principal types of theories have been proposed to explain X-ray bursts: instabilities in the accretion flow of matter onto a collapsed object[1–9], and thermonuclear flashes in the freshly accreted material on the surface of a neutron star[10–16]. Both mechanisms probably occur in nature but account for different observed phenomena[17]. The available evidence [17–19] leaves little doubt that the Type II bursts[17], which are emitted by MXB1730−335 (the Rapid Burster), are due to an accretion instability. The properties of Type I bursts[17], which are emitted by all burst sources (including the Rapid Burster), are naturally explained by the thermonuclear flash model[15]. In the light of this model, we discuss here the intrinsic persistent X-ray luminosity and the ratio of the average persistent X-ray luminosity to the time-averaged burst luminosity associated with Type I burst sources[17,20,21].

Following van Paradijs[22], we assume that the peak burst luminosity is a standard candle. The intrinsic persistent X-ray luminosity L_x in units of this standard candle is thus given by the ratio γ of the persistent X-ray flux to the average peak burst flux. On the basis of the results given below we argue that the bright non-bursting galactic bulge X-ray sources[23,24] are accreting neutron stars, which differ from X-ray burst sources in that L_x is above a certain critical value.

An earlier compilation of values of the ratio, α, of the average persistent X-ray luminosity to the time-averaged burst luminosity has been given by Lewin[20]; the α-values presented in Table 1 include more X-ray burst sources and are based on a larger collection of SAS 3 data on all well-studied burst sources. We confirm the earlier conclusion[15,21] that in general the observed values of α are consistent which the thermonuclear flash model.

Detailed calculations of thermonuclear processes in the surface layers of an accreting neutron star were recently reported by Joss[15] (see also refs 14 and 16). Joss's results indicate that such objects undergo helium-burning flashes, which are visible to an external observer as bursts of X rays. This model can account for most of the basic features of Type I X-ray bursts, and leads to the following predictions concerning the persistent X-ray luminosity of the Type I burst sources: (1) every burst source is also a source of persistent (accretion-driven) X-ray emission; hence, apart from efficiency factors[12], α is just the ratio of the gravitational potential energy liberated by accretion to the nuclear energy released in flashes and should have a value of ~100 (refs 12, 13, 15); and (2) bursts occur only when the accretion rate is below a certain critical value and the corresponding persistent luminosity is below a critical value L_c. This effect can be qualitatively understood as resulting from an increase in the pre-flash temperature and a decrease in the level

0028–0836/79/310375—03$01.00

© Macmillan Journals Ltd 1979

of degeneracy of the helium-burning shell, and from a decrease of the temperature gradient above the helium-burning shell, with increasing mass accretion rate[25]. The precise value of L_c is not yet well determined and may depend on other parameters (such as the strength of the neutron-star magnetic field). However, the available calculations[12,15] suggest that $L_c \approx 0.1\ L_{ed}$, where

$$L_{ed} = \frac{4\pi cGM}{\kappa} \simeq 1.25 \times 10^{38} \left(\frac{M}{M_\odot}\right)\left(\frac{\kappa}{0.4\text{cm}^2\,\text{g}^{-1}}\right)^{-1} \quad \text{erg s}^{-1} \quad (1)$$

is the Eddington luminosity for an object of mass M and an opacity coefficient of κ (normalised to Thomson scattering opacity in pure hydrogen). Bursts also should not occur when the accretion rate is below another critical value (at least two orders of magnitude smaller than L_c)[13], because the helium-burning will then be driven by pycnonuclear reactions[13].

In Table 1 we have collected the values of the observed persistent X-ray flux F_{per} and the ratios α and γ for 10 burst sources. Most of these results are based on data obtained from pointed SAS 3 Y-axis[26,27] observations; previous data sources are also listed in Table 1.

The data on MXB1820−30 have been taken from the SAS 3 rotation modulation collimator observations by Clark *et al.*[28]. The upper limit to the persistent X-ray flux from MXB1659−29 has been obtained from changes in the observed X-ray count rate when the source enters and leaves Earth occultation[18,21]. In the case of the Rapid Burster, we have used the time-averaged Type II burst flux for the persistent flux, as the Type II bursts presumably[17] replace the persistent flux. In April 1977, the observed upper limit to a truly persistent X-ray flux from this source was 20% of the average Type II burst flux[29]. For the faint X-ray source MXB1906+00, a determination of the persistent X-ray flux from the SAS 3 observations is difficult (due to contamination by Aql X-1 in the field of view[26]); we therefore used the average persistent X-ray flux of Seward *et al.*[30]. Because of source confusion problems and the transient character of the possible persistent X-ray counterparts, we have not included in Table 1 the three galactic centre burst sources[31–34]. Two sources (MXB1659−29 and MXB1820−30) became inactive when F_{per} rose above a certain value[28,35]; the corresponding values of γ are also given in Table 1. When different values of α were measured during observations of a given source, the range of observed values is presented.

According to calculations by Joss[12,15], the maximum luminosity in an X-ray burst is comparable to the Eddington limit. This result is supported by the empirical results obtained by van Paradijs[22], which strongly suggest that the average maximum luminosity L_0 of X-ray bursts is indeed about the same for all burst sources and is of the same order as the Eddington limit. Scaling their distances such that the burst sources are distributed symmetrically about the galactic centre yields $L_0 \sim 2 \times 10^{38}$ erg cm^{-2} s^{-1}. The intrinsic persistent X-ray luminosity L_x of a given burst source, in units of the luminosity standard L_0, is given by γ (see Table 1).

The following trends are visible in the distribution of the values of γ. First, the sources all have $\gamma < 0.3$ when active. This is consistent with the values for which the calculations by Joss[15] and Joss and Li[16] predict bursting behaviour. Second, the two sources which show the most irregular burst behaviour (MXB1735−44 and MXB1837+05[18,36–38]) have the largest values of γ of all sources in Table 1. The irregular burst behaviour of MXB1735−44 and MXB1837+05 may be related to the rather large persistent luminosity of these sources, which may lie near the critical value above which X-ray bursts are expected to be absent. (Note, however, that the behaviour of X-ray burst sources must depend on additional complications beyond these general considerations; in particular, there are few correlations between the level of burst activity and the instantaneous persistent X-ray luminosity in burst sources[37–40].

The values of α given in Table 1 are averages over time intervals of typically a few days. For most of the sources α is a relatively well defined quantity; the average total energy per burst from a given source, the time intervals between them and the value of the persistent flux do not vary greatly. We estimate that the values of α typically have a possible uncertainty of $\lesssim 50\%$. In some cases, however, the burst behaviour is quite irregular. An example is the source MXB1735−44, where the burst intervals vary from ~1–2 h to more than 50 h[18,21,36,37]. In those cases where appreciable irregularity of the burst activity is apparent, we have given separately in Table 1 the values of α during times of exceptional burst activity.

Table 1 X-ray burst source parameters

Source	F_x^* (erg cm^{-2} s^{-1})	α	γ	Refs

* Numbers in parentheses indicate powers of 10.
† No bursts observed above this value of the persistent X-ray flux.
‡ When two values are shown, the latter corresponds to intervals of high burst activity.
§ Time-averaged Type II burst flux.

Very high values of α are obtained for the irregular sources MXB1735−44 and MXB1837+05, when averaged over the entire period of observation; values between 100 and 200 are observed, however, during the periods of high burst activity. In the context of the thermonuclear flash model, these values for α suggest that during periods of burst inactivity the material in the freshly accreted layers on the neutron star undergoes relatively steady nuclear burning. This result is strengthened by the observation that the energy of the first burst after a long period of burst inactivity is about the same as for the bursts that occur throughout intervals of high burst activity. It may not, therefore, be necessary to invoke the "storage model," introduced by Woosley and Taam[10], in which nuclear fuel is accumulated during burst-inactive periods and is consumed only during periods of burst activity.

With one exception, the values of α in Table 1 fall in the range of ~50–~200 (during periods of high burst activity) which agrees well with the values predicted by the thermonuclear flash model. The low upper limit of 25 in the case of MXB1659−29 may perhaps result from bolometric corrections and anisotropic emission of the persistent flux[12,41,42], or from the mixing of hydrogen into the helium-burning shell[14].

Lamb and Lamb[13] suggested that the observed values of α were too small to be consistent with any thermonuclear flash mechanism, unless one invokes the "storage model" described above. Our conclusions differ from those of Lamb and Lamb[13] principally for the following reasons: (1) More detailed computations[15] indicate that the nuclear processing in a helium-burning flash proceeds all the way to iron-peak nuclei, thereby releasing ~2.7 times more energy per unit mass than in the simple fusion of helium into carbon. (2) We exclude the Type II bursts from the Rapid Burster, as these bursts are produced by a different physical mechanism than that responsible for Type I bursts[17]. (3) Preliminary estimates (see Lamb and Lamb[13]) of the

values of α from some sources were lower than the more accurate values given in Table 1.

The burst sources resemble the bright galactic bulge X-ray sources[23,24] in their galactic distribution[43] and in the spectra of their persistent X-ray fluxes[44,45]. In fact, some of the steady counterparts of the burst sources (such as MXB1735−44) can be categorised as bulge sources (see refs 24, 46).

Lewin *et al.*[43] suggested that the galactic distribution of X-ray burst sources was consistent with their being a sub-class of already known low galactic latitude X-ray sources, while Ostriker[44] and Markert *et al.*[45] have proposed that the burst sources are a subset of the galactic bulge and globular cluster X-ray sources on the basis of their spectral properties. However, the brightest of the galactic bulge sources, with luminosities of $\sim 10^{38}$ erg s^{-1}, have never been found to burst.

The classification of the galactic bulge sources into two groups by Parsignault and Grindlay[47], which is based on their X-ray spectra (Fe line emission) and the character of their brightness variations, largely coincides with a grouping of these sources according to absolute X-ray luminosity. This is shown by histograms of the apparent brightness[48] of the sources in these two classes, given that the galactic longitude distribution of the sources ($|l^{II}| \leq 20°$) indicates a small range of distances. Apparently the mass accretion rate is one of the most important parameters that determine the variability (including the presence of Type I X-ray bursts) and spectral properties of bulge sources.

In view of the results presented here we suggest more specifically (compare refs 43–45) that the majority of the galactic bulge X-ray sources are neutron stars that are undergoing accretion, and that the burst sources are a subset of the bulge sources whose accretion rate is below a critical value (and, perhaps, with other parameter values that permit bursting behaviour, such as weak magnetic fields[16]). For accretion rates above this value, the structure of the freshly accreted envelope on the neutron star is changed such that nuclear burning proceeds relatively steadily. Below this value, thermonuclear flashes occur which are observed as X-ray bursts.

The ring systems of Jupiter, Saturn and Uranus

THE recent direct observation by the Voyager spacecraft of a ring around Jupiter[1] makes a comparison between the jovian ring and the rings of Saturn and Uranus possible, and leads to certain conclusions about their origins which are reported here.

Studies made by Vsekhsviatsky[2] and described by Struve[3] of the position of an irregular dark line on Jupiter with respect to the subsolar point suggested the presence of a ring less than two jovian radii above the surface. This radius falls, however, beyond the Roche limit and beyond the satellite Amalthea. On the other hand Acuña and Ness[4] proposed that certain minima in the charged particle fluxes observed by Pioneer 11 are caused by a ring at 1.83 times the jovian radius[5], a value which agrees well with the Voyager results. Comparing the size of the minima caused by the ring with those caused by the nearby Amalthea one can conclude that the solid surface area of the ring should be about 20,000 km^2 assuming that only the geometrical cross-section plays a part.

It is interesting to compare the location and width of the rings of Jupiter, Saturn and Uranus with the various theoretical limits. Besides the classical Roche[6] limit a_R, which is defined as the smallest distance at which a liquid self-gravitating body remains spheroidal and does not breakup, there are the limits a_i and a_0 indicating the distances at which an incident or orbiting, spherical, homogeneous and defectless solid body will break up in a most fracture-resistant mode[7]; non-spherical bodies and those containing unavoidable defects will breakup, depending on their mode of fracture, at much larger distances. There are also two accretion limits[8], the lower one, a_l, denoting the distance below which only molecular accretion onto an orbiting particle is possible and the upper one, a_u, which is the smallest distance at which two particles of the same radii can accrete. For rotating particles, a between a_l and a_u, there is an upper limit of the radius of the larger particle onto which a smaller one can accrete. Beyond a_u all modes of accretion are possible and thus larger bodies can form. The various limits can be expressed as $a = C(M/\pi\rho)^{1/3}$ with $C_R = 2.21$, $C_0 = 1.25$, $C_i = 1.08$, $C_l = 1.31$ and $C_u = 2.62$; here M is the mass of the planet and ρ is the density of the ring particles. Figure 1 shows the location of the rings and the various limits for the three planets are indicated assuming that the rings are made either of ice ($\rho = 1$ g cm^{-3}) or of carbonaceous chondrites ($\rho = 3$ g cm^{-3}); the location of the nearest satellites is also shown. All the rings lie outside the a_i, a_0, a_l, limits some of which are even smaller than the indicated planetary radii. The jovian ring is below the Roche limit for both ice and chondrite, Saturn would agree with this limit if the density of ice and chondrite were 0.77 g cm^{-3} while Uranus would agree if the density were less than 2.2 g cm^{-3}. The upper accretion limit a_u is satisfied for both ice and chondrite for Jupiter and Uranus but only for ice for Saturn.

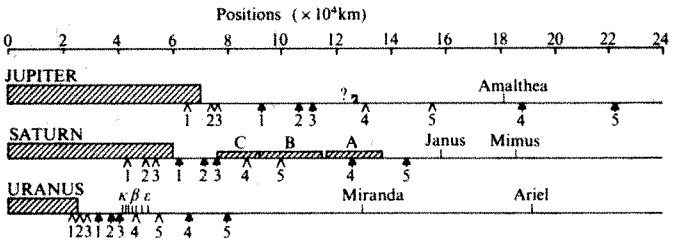

Fig. 1 The positions of the rings of Jupiter, Saturn and Uranus as well as those of their nearest satellites (above the lines) and of the various theoretical limits for densities 1 (▲) and 3 (△) g cm^{-3} (below the lines). The inner boundary of the jovian ring is uncertain. 1, Breakup of incident body a_i; 2, breakup of orbiting body a_0; 3, lower accretion limit a_l; 4, Roche limit a_R; 5, upper accretion limit a_u.

A ring which was formed by accretion of particles formed in the protoplanetary nebula would be expected to be located between a_l and a_u to make the process possible and to ensure that continuous collisional comminution does not lead to its disappearance through the action of radiation pressure, the Poynting–Robertson effect, and so on[9]. One would not expect the ring to be outside a_u because in that position accretion should be rapid and lead to the breakup of the ring into larger clumps and bodies. On the other hand a ring which was formed by the breakup of a body under the action of tidal forces should lie near a_i and a_0 only if the body was spherical and broke in a particular fracture-resisting manner[7]. Unless the body were very large, of the order of a few hundred km, one would not expect it to be spherical and it could thus breakup at any distance larger than a_i or a_0. The resulting ring would be rather narrow, it would tend to be lumpy, uneven in thickness, and if the initial fracture had produced a few larger pieces they may have formed distinct separate rings.

The above considerations agree with the conclusion that the saturnian rings, which fit so well between a_l and a_u, are made primarily of ice and that they are the product of condensation from the protoplanetary nebula and subsequent collisional spread. The 10 or so rings of Uranus are probably the result of a breakup of one or more bodies which were non-spherical and mechanically weak and probably of carbonaceous composition[9]. The formation and maintenance of distinct, separated rings was probably the result of resonances with various satellites[10]. The breakup of the body occurred probably not less than 10^7 or 10^8 yr ago because the rings seem to be continuous. The jovian ring is probably an example of a much more recently fragmented body which was non-spherical, mechanically weak and probably also of the carbonaceous kind. As pointed out by Pollack[11] the thermal history of Jupiter is unfavourable for the ring to form by condensation. If the width of the ring were 20–200 km, combining it with the total solid surface of the ring of 20,000 km^2 leads to an opacity one or two orders of magnitude lower than that of the weakest rings of Saturn which would explain the observational difficulties.

The tenuous nature of the ring may be due to continuous bombardment and erosion by the intense flux of protons in the jovian Van Allen belt. An estimate of this erosion can be made using a flux $\Phi = 2\times10^6$ cm^{-2} s^{-1} at 1–2 MeV and assuming $d\Phi/dE \sim E^{-1.5}$ dependence (ref. 12 and J. A. van Allen, personal communication), using Draine and Salpeter's[13] sputtering yields for $MgSiO_3$ and graphite and the sputtering yields for ice of Brown *et al.*[14]. One obtains an average erosion of 50–100 Å for ice, 2–3 for silicate and 0.2–0.5 Å yr^{-1} for graphite. Many small grains would thus be eliminated from the ring on the time scale of 10^6 yr once their size became small enough to be affected by radiation pressure, the Poynting–Robertson effect, and so on. In these circumstances the ring may show more rapid evolutionary changes than those expected to occur on the saturnian ring A[15] and may have a much shorter life than the rings of the two other planets.

Cyclic reaction mechanism in the electrodeposition of aluminium

DENDRITIC growth is one of the most serious problems encountered in the galvanic deposition of metals. For many applications a high deposition rate is required but the rate cannot exceed the transport rate of metal ions to the electrode. A method of solving the transport problem by a cyclic mechanism is presented here, which combines the electrode process with a subsequent chemical reaction.

Metallic layers deposited in diffusion-controlled conditions are incoherent and powdery and are therefore not suitable for normal applications. But even at lower deposition rates the formation of the metallic layer will be influenced by diffusion. Because of the concentration gradient due to the electrode reaction, metallic nuclei that protrude in the depleting solution will grow faster than the others. The roughness of the electrode surface will be magnified and after a certain time dendritic growth will be observed. Levelling agents are added to industrial galvanic solutions to avoid dendrites. In most cases the levelling effect of these agents is due to their adsorption on a growing nucleus and the resulting deactivation of the nucleus. New nuclei have to be formed continuously and the result is a smoothly growing surface.

Instead of poisoning a growing nucleus we propose to solve the transport problem itself by combining the electrode process

with a subsequent chemical reaction so that the concentration of the active compound remains constant at the electrode surface:

$$A + ne^- \rightarrow M + B \quad (1)$$

$$Z + B \rightarrow A + D \quad (2)$$

where A represents the active compound, M the deposited metal and Z an electrochemically inactive compound present in the solution at high concentration and is capable of producing A. In a cyclic process the compound A is reduced at the electrode (1) but regenerated in a fast chemical reaction (2).

Reaction mechanisms of this type are well known in catalysis where a low activation energy is required for the reaction (1)

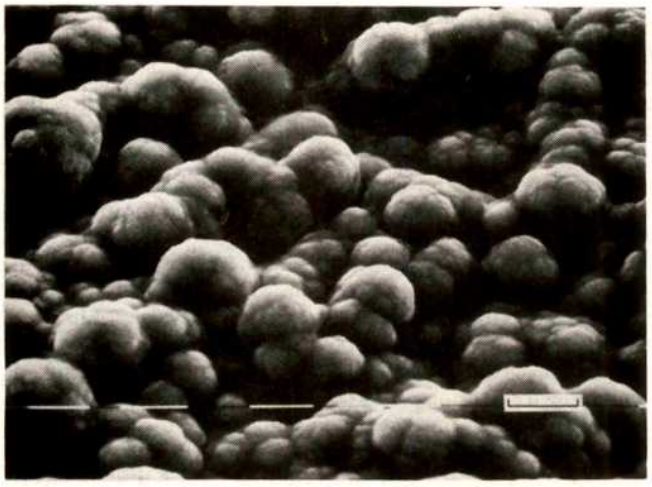

Fig. 3 Scanning electron micrograph of aluminium deposited at 3.5 mA cm^{-2} and 25 °C for 90 min from a solution of 0.17 M $AlH_3 \cdot 2Et_3N$ in $LiAlH_4$–THF. Scale bar, 10 μm.

promoting the conversion of Z into M. To obtain a cyclic electrodeposition process it is essential that the overpotential for the deposition of M from A (1) is smaller than that for the reduction of Z into M.

For the electrodeposition of aluminium Brenner[1] introduced a solution of $LiAlH_4$ and $AlCl_3$ in diethylether (Et_2O). Very pure aluminium with a high cathodic efficiency can be obtained with this solution. Levinskas[2] proposed the following reaction for the electrode process:

$$AlCl_2(Et_2O)_2^+ + 3e^- \rightarrow Al + 2Cl^- + 2Et_2O$$

We think, however, that the electrode process occurs by means of a cyclic mechanism as given in reactions (1 + 2) where AlH_3 is the active compound 'A' in the electrodeposition. The compound is regenerated in the reaction of $AlCl_2 \cdot (Et_2O)_2^+(Z)$ with hydride ions (B). The first evidence is the observation that no aluminium metal can be deposited from a solution of $AlCl_3$ in diethylether without decomposing the solvent. This rules out the scheme of Levinskas. In contrast very pure aluminium is deposited from a solution of $AlH_3 \cdot 2Et_3N$, $LiAlH_4$ in diethylether[3]. This shows that the overpotential for the aluminium deposition is larger for $AlCl_3$ than for AlH_3. The deposition rate is limited by mass transport as shown from the diffusion plateau of the current–overvoltage curve (Fig. 1*a*). The chronoamperogram (Fig. 2) measured at −403 mV also shows this diffusion dependence.

The variation of the current as a function of time is in good agreement with the Cottrell equation:

$$i = \frac{nFSD_A^{1/2}C_A^0}{(\pi t)^{1/2}}$$

Electrodeposition at a current density of 3.5 mA cm^{-2} results in a rough and spongy surface as shown in Fig. 3. This structure is a precursor of dendritic growth.

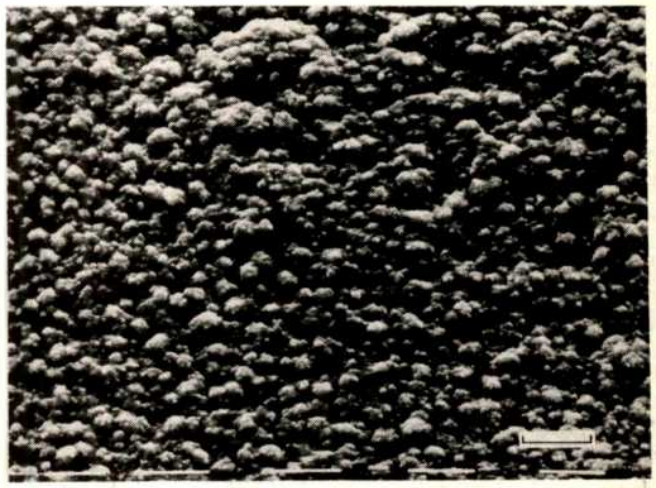

Fig. 4 Scanning electron micrograph of aluminium deposited at 21 mA cm^{-2} and 25 °C for 15 min from a solution of 0.17 M $AlH_3 \cdot 2Et_3N$, 0.44 M $AlCl_3 \cdot 2THF$ in $LiAlH_4$–THF. Scale bar, 10 μm.

The compound AlH_3 was obtained in a pure and crystalline form as an adduct with triethylamine: $AlH_3 \cdot 2Et_3N$. For the electrochemical measurements the less volatile tetrahydrofuran (THF) was used instead of diethylether as the solvent. The measurements were carried out with a special cell design in which the aluminium reference electrode was located in a cavity behind the working electrode ensuring a very small ohmic drop between working and reference electrodes.

When $AlCl_3 \cdot 2THF$ is added to the previous solution of $AlH_3 \cdot 2Et_3N$, $LiAlH_4$ in THF the situation is completely changed. There is no diffusion plateau in the voltammogram

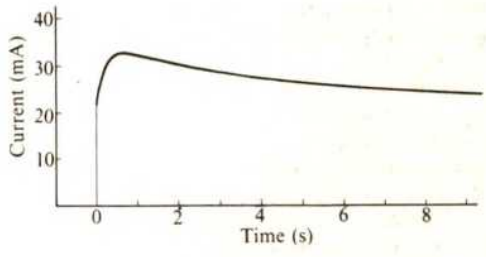

Fig. 5 Chronoamperogram for the deposition of aluminium in a 0.17 M $AlH_3 \cdot 2Et_3N$, 0.44 M $AlCl_3 \cdot 2THF$ solution at −403 mV and 25 °C.

(Fig. 1*b*) and compact aluminium layers are obtained even at higher current densities (Fig. 4).

The chronoamperogram (Fig. 5), also measured at −403 mV, indicates that in this case the current is no longer diffusion controlled. We explain this by the following cyclic process:

$$AlH_3 + 3e^- \rightarrow Al + 3H^-$$

$$AlCl_2(THF)_4^+ + 3H^- \xrightarrow{k_2} AlH_3 + 2Cl^- + 4THF$$

The chemical reaction maintains a constant concentration of the active compound at the electrode and the result of the process is the deposition of a compact aluminium layer. The measured values of the current as a function of time are in good agreement with the equations derived by Delahay[4].

$$i = nFSD_A^{1/2}C_A^0(k_2C_Z^0)^{1/2}\,erf\,(k_2C_Z^0t)^{1/2} + \frac{nFSD_A^{1/2}C_A^0}{(\pi t)^{1/2}}\exp(-k_2C_Z^0t)$$

The rate constant $k_2 = 11.7\ s^{-1}\ mol^{-1}\ l$ (in THF at 25 °C) of the chemical process can be calculated from the chronoamperometric measurements. The value of the rate constant k_2, together with the concentration of $AlCl_3$ (C_Z^0), defines the limits between which the cyclic process can function.

We believe that a cyclic mechanism can also explain the effect of adding cyanide compounds to an aqueous solution used for the electro-deposition of zinc. It is found[5] that $Zn(OH)_2$ is the active compound in the electrode reaction but it is also known that the presence of cyanide ions gives smoother deposits than those obtained from zincate alone[6].

In a cyclic process the diffusion limitation of $Zn(OH)_2$, which is only present at a low concentration level, is removed by the chemical regeneration of $Zn(OH)_2$ in the reaction of $Zn(CN)_4^{2-}$ with hydroxide ions.

Effects of acetylene and soil water content on emission of nitrous oxide from soils

THERE are fears that increased nitrogen fertilisation of soils may increase release of N_2O from soils through denitrification of nitrate and thereby pose a threat to the stratospheric ozone layer protecting the Earth from biologically harmful UV radiation from the Sun[1–6].

Most of the fertiliser nitrogen added to soils is in the form of ammonium or of ammonium-producing compounds such as urea. Before this nitrogen can be converted to N_2O by denitrifying microorganisms, it must be oxidised to nitrite or nitrate by the nitrifying microorganisms in soils. Studies with pure cultures[7] have shown that at least one of these nitrifying microorganisms (*Nitrosomonas europaea*) can produce N_2O during oxidation of ammonium to nitrite, so the possibility that nitrifying as well as denitrifying microorganisms contribute to N_2O emissions from soils must be considered. Recent work[8,9] has shown that N_2O emissions from well aerated soils treated with ammonium sulphate greatly exceeded N_2O emissions from the same soils treated with an equivalent amount of nitrogen as potassium nitrate and were greatly reduced by addition of nitrapyrin [2-chloro-6-(trichloromethyl)-pyridine], which inhibits nitrification of ammonium in soils[10,11] but has little or no effect on denitrification of nitrate by soil microorganisms[12]. These observations indicated that most of the N_2O evolved from well aerated soils treated with ammonium or ammonium-producing fertilisers is formed during oxidation of ammonium to nitrite by nitrifying soil microorganisms and that these microorganisms contribute significantly to N_2O emissions from soils. We report here further evidence for these conclusions. This evidence was obtained by studying the effects of acetylene (C_2H_2) on N_2O emissions from soils incubated at different water tensions after treatment with ammonium sulphate or potassium nitrate. The effects of C_2H_2 were studied because recent work has shown that this gas inhibits reduction of N_2O to N_2 by denitrifying microorganisms in soils or pure cultures without affecting reduction of nitrate to N_2O by these microorganisms[13–17] and also inhibits oxidation of ammonium by *Nitrosomonas europaea*[18] and the nitrifying microorganisms in soils[19].

The soils used (Table 1) were screened (<2 mm) samples of field-moist surface soils selected to obtain a range in properties. Subsamples containing 30 g of soil were incubated at 30 °C after treatment with ammonium sulphate or potassium nitrate (100 μg N per g) and adjustment of their water contents to the equivalent of 0, 10 or 100 cm of water tension. Incubations were performed under air or air containing 0.1% (v/v) C_2H_2 in 1.2-l glass bottles fitted with ground glass joints and glass stopcocks, and the atmospheres in the bottles were sampled for N_2O analysis and renewed after various times. Nitrous oxide was determined by a gas chromatographic technique that utilises the xenon in air as an internal standard[20]. Soil water tension was determined by the tensiometer described by Rose[21], and nitrogen as (nitrite + nitrate) present in soils before and after incubation was determined as described by Bremner and Keeney[22].

Table 1 shows the effects of C_2H_2 on the amounts of nitrogen as N_2O and as (nitrite + nitrate) produced on incubation of well aerated samples of ammonium-treated soils. Besides confirming that C_2H_2 is a potent inhibitor of nitrification in soils, the data reported show that this gas inhibited production of N_2O in ammonium-treated soils. This is evidence that most, if not all, of the N_2O evolved from these soils in the absence of C_2H_2 was produced by nitrifying microorganisms.

Further evidence for this conclusion is reported in Table 2, which shows the effects of C_2H_2 and soil water content on the amounts of N_2O evolved from soils treated with ammonium sulphate or potassium nitrate. The data reported show that the amounts of N_2O evolved from ammonium-treated soils at water tensions ranging from 0 to 100 cm increased with increase in soil water content and greatly exceeded the amounts evolved from the corresponding nitrate-treated soils. Table 2 also shows that

Table 1 Effects of acetylene on amounts of nitrogen as N_2O and as (nitrite + nitrate) produced on incubation of ammonium-treated soils under aerobic conditions

Webster	Ammonium	0	34	1	42	2	52	4
		10	29	1	35	1	44	2
		100	18	<1	23	<1	31	<1
	Nitrate	0	2	<1	6	2	6	3
		10	1	<1	3	1	4	2
		100	1	<1	2	<1	3	<1

Soils supplemented with N (100 μg per g soil) as ammonium sulphate or potassium nitrate were incubated at various water tensions under air or air containing 0.1% (v/v) C_2H_2. Atmospheres in incubation flasks were renewed after 2, 4, 7, 9 and 11 days.

C_2H_2 greatly reduced evolution of N_2O from ammonium-treated soils and that the amounts of N_2O evolved from these soils in the presence of C_2H_2 were similar to, or greater than, the amounts evolved from the corresponding nitrate-treated soils. Since C_2H_2 inhibits production of N_2O via oxidation of ammonium by nitrifying microorganisms but promotes release of N_2O during reduction of nitrate by denitrifying microorganisms, these observations seem to leave no doubt that most of the N_2O evolved from the ammonium-treated soils in the work reported was produced during oxidation of ammonium by nitrifying soil microorganisms and that very little of this gas was produced through reduction of nitrate by denitrifying microorganisms.

Our finding that N_2O emissions from ammonium-treated soils increased markedly as the soil water tension decreased (that is, as the soil water content increased and the availability of oxygen to soil microorganisms decreased) is readily explained if nitrifying microorganisms are responsible for these emissions. Ritchie and Nicholas[23] have shown that *Nitrosomonas europaea* produces an enzyme that allows it to reduce nitrite to N_2O during oxidation of ammonium and thereby utilise nitrite as a terminal electron acceptor instead of oxygen when the supply of oxygen is limited.

Our conclusion that nitrifying microorganisms contribute substantially to N_2O emissions from soils is supported by field studies showing that N_2O emissions from plots fertilised with nitrogen as ammonium sulphate exceeded those from corresponding plots treated with an equivalent amount of nitrogen as calcium nitrate (A. D. Matthias, A.M.B. and J.M.B., unpublished).

Other evidence that nitrification deserves much greater attention in research on sources of atmospheric N_2O has been provided by recent work[24,25] indicating that nitrification may be the major source of N_2O in the oceans.

Non-uniform vertical distribution of fine sediment in the Amazon River

IN studies of sediment transport in rivers, it is frequently assumed that suspended particles finer than a certain size (usually of the order of 60 μm) are uniformly concentrated from river bed to water surface[1,2]. The assumption seems to be mostly a matter of convenience; it is well established that the vertical concentration gradient for sediment particles suspended in rivers is directly proportional to fall velocity of the particles and inversely proportional to shear velocity of the flow[3]. For very fine particles suspended in highly turbulent flows, concentration gradient may be small; the assumption has been used, therefore, to justify collection of near-surface samples in streams where velocities are high and turbulence is intense[2]. Our recent studies of sediment in suspension in the Amazon River show that this assumption is not valid for deep rivers and that appreciable errors result from using concentrations of surface samples to represent concentration of suspended sediment and its associated adsorbed constituents through the entire stream depth.

During high-water seasons of 1976 and 1977, we collected samples of water and sediment in the Amazon River between the mouth and Iquitos, about 3,700 km upriver from the mouth. We used a variety of sampling equipment aboard RV Alpha Helix: Niskin bottles, a point sampler, a depth-integrating

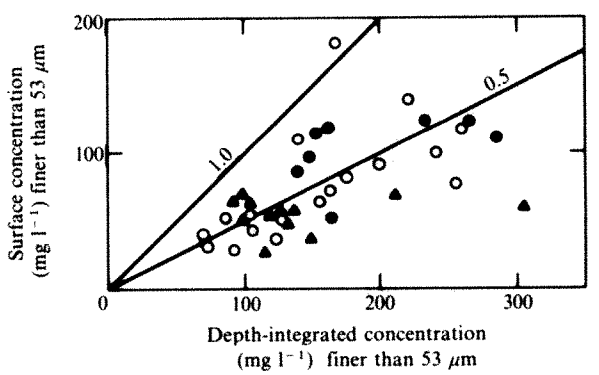

Fig. 1 Relations between concentrations of fine-grained suspended sediment at the river surface and in depth-integrated samples in the Amazon River mainstem near Iquitos, at São Paulo de Olivença, at Santo Antônio do Içá, at Itapeúa (near Coari), near Manacapuru, and at Óbidos. Samples collected between 20 May and 2 June 1977. Points are coded by river depth: ●, depths ≤24 m; ○, 24–49 m; ▲, ≥50 m. Lines through the graph are not regression lines, but are reference lines to show ratios of surface to depth-integrated concentrations.

sampler, and a bucket. The Niskin bottle, which has become standard sampling equipment in most US-based research on the chemistry of the oceans, is lowered open to the desired depth and then closed by a messenger sent down the wire. The point sampler we used is a modified version of the US P-63 sampler that is used in deep rivers of North America[2]: it has a nozzle that faces directly into the flow and that is designed to admit water at its ambient velocity in the river. The nozzle has a valve that can be opened and closed by remote control after the sampler has been lowered to the desired depth. As the sampler is lowered into the flow, air is compressed in the sample container so the pressure inside the container and in the flow are equal. This is to avoid an initial surge into the sampler when the valve is suddenly opened, which will bias the sample[2]. Our sampler had an auxiliary air chamber to allow pressure equalisation to depths of 100 m. The depth-integrating sampler we used is an enlarged modification of the type of sampler with which most river-sediment samples are collected in the US[2]. It has the same type of nozzle as the point sampler (but without a valve that closes it), and it is lowered to the river bed and back to the surface at a uniform vertical rate. The resulting depth-integrated sample is thereby weighted for differences in velocity in the vertical, and the concentration of sediment in the sample is a velocity-weighted average concentration. Our simplest piece of equipment was a bucket with which we dipped some of the samples from the river surface. Details of our sampling and analytical procedure including a list of our data are given elsewhere[4,5].

The particle-size analyses represented in Figs 1 and 2 were carried out by several procedures. Samples collected in 1976 were separated entirely aboard ship by sieve (sizes >63 μm) and pipette (sizes <63 μm). The sieved and pipetted fractions were preserved (latter on preweighed Nucleopore filters having a pore diameter of 0.4 μm) for later weighing in the laboratory in Edinburgh. Samples collected in 1977 were all passed through a 53-μm sieve aboard ship, and material caught on the sieve was preserved for more detailed sieve analysis in the laboratory in Denver. Suspensions of fine sediment that passed the 53-μm sieve were mostly filtered aboard ship onto preweighed Millipore filters (nominal pore diameter 0.45 μm) for later weighing in Denver. However, some suspensions of particles finer than 53 μm were bottled and returned to the US for detailed pipette analysis of the silt and clay sizes. Shipboard pipette analyses made in 1976 used river water without added dispersants. Pipette analyses made in the US in 1977 used distilled water and dispersing agents[6].

Figure 1 compares concentrations of fine-grained (less than 53 μm) suspended sediment collected within 1 m of the water surface with the concentrations collected at the same sites from the full depth of water by the depth-integrating sampler. Samples represented in Fig. 1 were collected at six cross-sections spaced along 3,000 km of the Amazon mainstem between Iquitos, Peru, and Óbidos, Brazil. In general, concentration of fine material in suspension at water surface is about half the average fine-material concentration in the full depth of the river. This does not support Gibbs' report[7] that samples collected at 0.9 total depth (0.1 of the distance from river bed to water surface) in the Amazon had only a 20% greater concentration of suspended sediment than samples collected from river surface at the same sites. Samples taken at 0.9 total depth should have even greater concentration than depth-integrated average concentrations shown in Fig. 1. Furthermore, when total suspended concentration is considered (that is, when material >53 μm is included), the difference between near-surface and near-bottom concentrations is even greater[4].

Is there a minimum particle size below which concentration in suspension from bed to river surface is uniform? Figure 2 shows the results of size analyses of samples taken at three different localities with three different types of equipment. The analyses show that particles even as small as 10 μm are not uniformly distributed. In two of the three sets of analyses shown in Fig. 2, concentrations of particles as small as 1 or 2 μm show slight but discernible differences between bottom and surface.

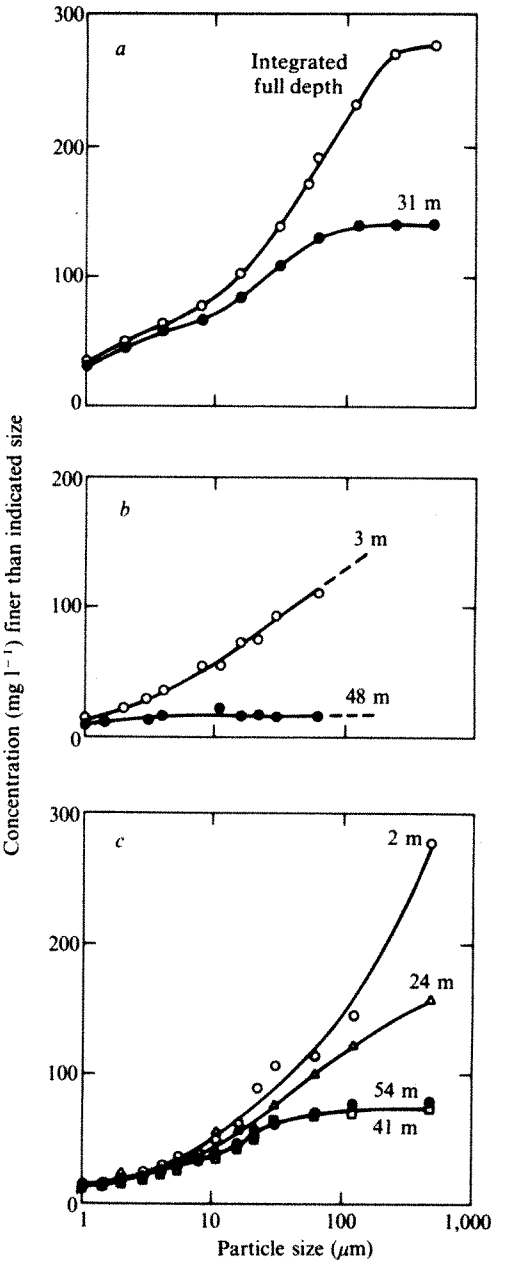

Fig. 2 Particle-size distributions of suspended sediment collected by different sampling methods in the Amazon River. Numbers by each curve indicate distances of samples above the river bed. *a*, Samples collected by depth-integrating sampler through the full depth of the river (from surface to bed and back to surface) and by the integrating sampler at a single depth of 1 m below surface (31 m off river bed). Each curve represents a composite of two samples taken in left centre part of the channel at São Paulo de Olivença, 22 May 1977. *b*, Samples collected by 30-l Niskin bottles 3 m above river bed and at river surface (48 m off river bed) in centre of channel near Manacapuru, 22 June 1976. *c*, Samples collected by point sampler at 2 m, 24 m, 41 m, and 54 m above river bed in left centre part of channel at Óbidos, 14 June 1976. Particle-size distributions at 41 m and 54 m were not sufficiently different to warrant separate lines through their points. Uppermost sample (54 m above the bed) was taken at a depth of 9 m below water surface.

We conclude that, in a river as deep as the Amazon, one cannot assume that suspended particles coarser than 1 μm are uniformly distributed in suspension. In the Amazon, as well as in other large rivers of the world, estimates of sediment yield and flux of suspended chemical constituents that are based only on surface samples are likely to contain significantly large errors.

We acknowledge the support given by the NSF to Scripps Institution of Oceanography for the operation of RV Alpha Helix. John M. Edmond of Massachusetts Institute of Technology was Chief Scientist of the Amazon cruises. Holly A. Mahoney and Bruce M. Delaney of the USGS analysed parts of the 1977 samples. Palaeomagnetism of stalagmite deposits

VARIOUS sedimentary deposits have recently been studied with the aim of producing geomagnetic field curves representing the Brunhes epoch. Unfortunately the magnetic recording process tends to be subject to several depositional and post-depositional errors and in the light of these Watkins[1], Verosub[2] and Verosub and Banerjee[3] have reviewed many of the claims that have been made for secular variation and anomalous field behaviour. The corresponding age data, provided by ^{14}C, uranium series disequilibrium and other methods may also suffer from such errors as bioturbation and migration of radionuclides. It has been shown that most speleothems (here stalagmites and flowstones) may be dated by uranium series methods to an age limit of 350,000 yr BP[4]. With the aim of finding an alternative continuous magnetic record we have studied the natural remanent magnetism (NRM) and ages of speleothems from the Canadian Rockies, the UK and elsewhere. We report here briefly on two of them and in greater detail on a third.

Each speleothem was oriented in the cave using mounts carrying a compass and a clinometer. The sample was cast in plaster of Paris in the laboratory where it was then sawn parallel and perpendicular to growth horizons, usually into 2-cm cubes. The procedure consisted of measuring the NRMs, carrying out a pilot alternating field demagnetisation and then remeasuring the specimens, alternating field cleaned to an optimum level. Fisher statistics were used to find a mean direction for all specimens from the same growth horizon and this direction was then reoriented from its laboratory to its site value.

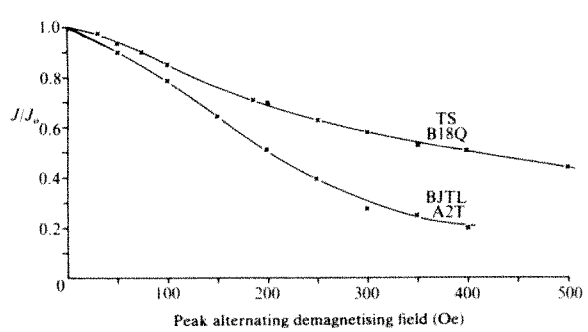

Fig. 1 Specimen demagnetisation curves, where J/J_0 is the ratio of the cleaned magnetisation to the NRM.

A flowstone BJTL, 7 cm thick, was collected from Bear Jaw cave near Crow's Nest Pass, Alberta, Canada (Table 1). $^{230}Th/^{234}U$ ratios obtained for the upper growth horizons showed that it was older than 350 Kyr BP (Table 2). Nevertheless, the magnetic results were encouraging in that (1) the major part of the NRM appeared to be stable, the median demagnetising fields of four test specimens all being greater than 180 Oe (Fig. 1 specimen BJTL A2T), with little shift of the concurrent vector direction; (2) the declination (D) and inclination (I) values were apparently not influenced by surface effects (the flowstone growth horizons dipped at about 28.5° in a direction of 298°). The magnetic intensity ranged from 3×10^{-9} to 2×10^{-8} emu g^{-1} (the Toronto ScT magnetometer used here has a quoted sensitivity of 2×10^{-7} emu).

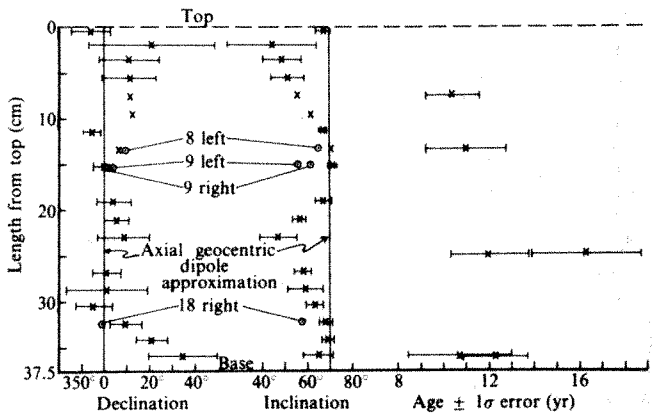

Fig. 2 Declination, inclination and dates of the Kingsdale stalagmite TS. (Direction errors of the lateral specimens have been omitted for clarity.)

A 13-cm thick flowstone from Eagle Cave, Crow's Nest Pass, was reversely magnetised throughout and together with its radioisotope ratios, this suggests that it grew near the end of the Matuyama epoch.

Several speleothems collected subsequently showed very low magnetic intensities. Where the signal was low but the growth layers well defined, greater signal strength was obtained by stacking adjacent specimens of the same growth horizon (suggested by M. L. Glasser). Such was the case of sample TS, a 37-cm high stalagmite from Kingsdale, Yorkshire, UK. Three vertical slices were obtained from the centre of the stalagmite and specimens from the middle cuts were stacked in two's and three's for NRM measurement (Table 1 and Fig. 2). Visual examination of the sample indicated continuous growth from the base, possible flood events having occurred at the levels of cuts 18 and 19, where there is dark opaque detrital material containing quartz grains. Because of their higher intensity, specimens from these lower cuts did not need to be stacked for measurement. Between 1 and 2 cm from the top, at cut 2, there is a concave upwards layer and irregular lateral crystal growth which probably indicates dissolution and hence a growth hiatus. At the time of collection the upper surface was wet, indicating that the top centimetre was probably of recent origin.

Figure 1 shows the alternating field demagnetisation of specimen TS B18Q; the median demagnetisation field was about 400 Oe and the direction moved only slightly from D = 6.4°, I = 60.0°, to settle around D = 10° and I = 63°. In view of

* Errors from $\alpha_{95} = \cos I.\delta D = \delta I$.
† Two specimens stacked to give one vector.
‡ Three specimens stacked in two's and then all three together to give four vectors.
§ B11Q possessed an anomalous cleaned direction of 353° and −32° after vecor subtraction and has therefore been excluded from the alternating field demagnetised mean. We do not know the reason for this.
‖ Cuts 10 and 14 were not measured because of extensive shattering incurred during the casting process. B14Q and D14Q have been used for dating purposes.
¶ Cut 18 also included specimen D19R which had exactly the same growth horizons.

the low intensities of the middle specimens it was felt that 50 Oe was an optimum demagnetising field. For most cuts the precision has increased on cleaning.

If speleothems possessed some kind of detrital remanent magnetism (DRM) the surface of deposition would be expected to have had an effect on the NRM directions. To test for this, specimens were prepared from the vertical sides of the Kingsdale stalagmite. They were taken from cuts 8 left-, 9 left-, 9 right- and 18 right-facing sides and contain, more or less, horizons spanning cuts 1 to 7,8,8 and 17 respectively. Their values (Table 1 and Fig. 2) are in accordance with other values for these layers, strongly suggesting that neither the D nor I values have been influenced by surface effects. This in turn points to a remanence of chemical origin.

The speleothem specimens have been dated by the $^{230}Th/^{234}U$ method assuming that no ^{230}Th was initially present and that the system had remained closed after initial deposition of the uranium. (Detrital thorium contained in the soluble fraction is detectable by the presence of ^{232}Th in the α-particle spectrum. Our method also takes into account the excess of ^{234}U over ^{238}U.) Radiometric data for TS (Table 2 and Fig. 2) show that it is young; the low uranium content renders the data imprecise. The stalagmite appears to have grown from about 12,500 yr BP, and was later redissolved down to an horizon which grew at about 10,000 yr BP, the remaining cap having been deposited more recently. Thus between 12.5 and 10 kyr BP it grew at 20 cm kyr^{-1}.

To test whether the stable primary magnetisation was syngenetic with its host growth horizon we have compared the modern field direction of the Kingsdale area with that for the upper cap of the Kingsdale stalagmite. (This is in contrast to many lake or marine cores where the tops are either missing or are severely disturbed. Note also that NRM direction errors, especially of inclination, may often go undetected in such cores.)

* Low ^{232}Th count rates indicated the essential lack of detrital thorium in the Kingsdale TS sample.

The modern field direction is $D = 8°W$, $I = 69°$, while the three specimens of cut 1 which was only 1 cm in depth have a mean direction of $D = 6°W$ and $I = 67°$ with an α_{95} of 3.5°; this is probably an average of the past 50 yr or more.

Of nine other speleothems which we have analysed, two are too weakly magnetised to be measurable, two show large viscous instabilities, and the remainder have stable, measurable NRMs. The latter, like the Bear Jaw and Kingsdale samples, have NRMs apparently unaffected by surface forces such as roughness, water flow, crystal growth habit or the dip of the growth layers, and this again supports the idea of a chemical remanent magnetisation. Hysteresis curves obtained for several specimens show saturation fields of around 3,000 G and coercivities of remanence between 140 and 350 G; this indicates that magnetite is the major carrier of the remanence.[5]

Although the stable remanence of speleothems is often weak, our findings indicate that in many cases we will be able to produce good records of secular variation in D and I. We expect the uranium concentrations will be sufficient to allow us to assign accurate absolute ages to most of these records.

A disadvantage of this method is that speleothems are objects of great natural beauty which once removed from a cave cannot be replaced. It is better to investigate limestone quarries where caves are sometimes breached and where speleothems may in any case be destroyed.

Research was supported by grants from the National Research Council to H.P.S., D.C.F and G.W.P. and from the Department of Energy, Mines and Resources (Geological Survey of Canada) to H.P.S. and D.C.F. Growth rate of a clam from the Galapagos Rise hot spring field using natural radionuclide ratios

THE submarine hydrothermal springs on the Galapagos Rift are the sites of lush biological populations supported ultimately by sulphur-oxidising bacteria utilising hydrogen sulphide transported from depth by the springs[1]. Two types of bivalves, one a mytilid mussel and the other a vesicomyid, have been recovered from these thermal regions. The shells of these organisms are as much as 30 cm long. We are determining growth rates of these organisms using a method which measures natural radionuclide content[2]. In this report we present our first results on a clam collected in the February–March 1977 Alvin dive series.

A 22 cm long valve of an articulated but dead specimen of a vesicomyid clam from the active thermal spring area, called Clambake I[1], at a depth of about 2,500 m, was analysed for the radionuclides listed in Table 1 within 1 yr after collection. The valve was cut in half from the hinge to the growing edge. The analyses were made on aliquots of the pulverised and homogenised half with the other half remaining intact for growth structure analysis and other studies. The analytical procedures involve α-spectrometric techniques for the metallic radionuclides (except ^{226}Ra which was determined by scintillation counting of ^{222}Rn)[3], and liquid scintillation analysis for radiocarbon assay[4].

Using the data shown in Table 1 we can first set upper limits to the age of the clam by making limiting assumptions about the radiochemical composition of the water from which the clam deposited its shell. In all of these calculations we assume a constant mass deposition per unit time growth law. We do not yet know the exact growth law for these deep-sea clams but shallow water clams generally show the following pattern[5]: an initial slow growth followed by a quasi-linear mass increase with time and then a slowing down at old age. By assuming that at all times in the life of the Galapagos Rift vesicomyid it deposits shell at a constant mass rate we will be erring in the direction of calculating too old an age.

The lowest $\Delta^{14}C$ value for dissolved inorganic carbon at depth in the eastern South Pacific measured in the GEOSECS programme by Ostlund *et al.*[6] is −240. If the shell grew with a constant mass per unit time, then its age can be calculated by the equation: $A/A_0 = (1 - e^{-\lambda t})/\lambda t$, where A is the activity after time t and A_0 is the initial activity. The calculated age by this model is about 500 yr. The assumption that the water from which the shell grew is unmodified ambient Pacific deep water conflicts with the observations[1]. Indeed a significant amount of dissolved inorganic carbon is released by the vents to the bottom water. This carbon can only be lower in ^{14}C than the ambient dissolved carbon whether it is imprinted by mantle material or old calcium carbonate deposits on the ridge flanks.

The $^{210}Pb/^{226}Ra$ activity ratio in the shell is 3.8. Without independent information of the $^{210}Pb/^{226}Ra$ ratio of the bottom water in this region an age assignment cannot be made. We proceed as follows. If the ^{226}Ra activity is 60 d.p.m. per 100 kg (P. E. Biscaye, personal communication) and the ^{222}Rn activity is 6,000 d.p.m. per 100 kg (J. Dymond and J. Edmond, personal communication), then in steady state conditions, with the ^{210}Pb activity equalling the ^{222}Rn activity, the expected initial activity ratio of $^{210}Pb/^{226}Ra$ would be about 100 in the water. If no strong fractionation between ^{210}Pb and ^{226}Ra occurred during shell deposition[7] this would also be the initial ratio in the shell. A constant growth model would then yield an age of 830 yr. It is unlikely that the ^{210}Pb produced from the radon would persist in solution, however. Rather it will be scavenged by the precipitating ferromanganese oxides found everywhere in the region

Table 1 Radiochemical analyses of a vesicomyid clam from the Galapagos Rift (Clambake I)

	Activities (d.p.m. g^{-1})
^{226}Ra	0.0515 ± 0.0022
^{228}Ra	0.00200 ± 0.00029
^{228}Th	0.00135 ± 0.00030
^{210}Pb	0.195 ± 0.006
	Activity ratio
$^{234}U/^{238}U$	1.19 ± 0.08
$^{228}Th/^{228}Ra$	0.68 ± 0.18
$^{228}Ra/^{226}Ra$	0.039 ± 0.006
$^{210}Pb/^{226}Ra$	3.79 ± 0.20
$\delta^{14}C$	−213 ± 8
$\Delta^{14}C$	−263 ± 10

All measurements are corrected to time of collection. Sample is designated G3-2(L) obtained on drive 713 (approximately 0°47.6′ N, 86°09′ W).

including on the shells of living mussels. As the estimated ^{210}Pb value in the water from which the shell is growing is diminished the calculated age of the clam will also become smaller.

The $^{228}Ra/^{226}Ra$ activity ratio of the shell provides a third method of setting an upper limit. This will, however, be more constraining than the previous two methods since two isotopes of the same element are involved and the limits on the ratio of the two isotopes in the water can be more accurately defined. An upper limit to the $^{228}Ra/^{226}Ra$ ratio in the water is set by the ratio of $^{232}Th/^{238}U$ in the basalt undergoing leaching. Mid-ocean ridge basalts have a Th/U weight ratio of around 2 (ref. 8). This corresponds, at secular equilibrium, to a $^{228}Ra/^{226}Ra$ activity ratio of about 0.65. If this were the ratio for the water from which the clam deposited its shell, the constant mass growth law age would be 140 yr.

The only direct method of arriving at the growth rate of the clam is by the use of the $^{228}Th/^{228}Ra$ activity ratio. ^{228}Ra is supplied to the water at the ocean bottom from the ocean floor rocks and sediments as the result of production by radioactive decay of ^{232}Th and diffusion. Once in the water ^{228}Ra decays with a half life of 5.7 yr to ^{228}Th which decays with a half life of 1.9 yr. As the shell grows it adds ^{228}Ra, presumably with little or no ^{228}Th, just as it adds ^{226}Ra. As the deposited shell material ages, ^{228}Ra decays within the shell to ^{228}Th which itself is subject to radioactive decay. Using our assumption that the rate of precipitation of calcium carbonate by the organism is constant with time during its life, the average $^{228}Th/^{228}Ra$ activity ratio of the whole shell will be a unique indicator of its age at time of capture. The relevant equation is:

$$\frac{A_T}{A_R} = \frac{\lambda_T}{\lambda_T - \lambda_R}\left[1 - \frac{\lambda_R(e^{-\lambda_T t} - 1)}{\lambda_T(e^{-\lambda_R t} - 1)}\right]$$

where R and T refer to ^{228}Ra and ^{228}Th respectively and A values are activities.

Figure 1 shows the plot of $^{228}Th/^{228}Ra$ activity ratio for the whole shell as a function of age of organism assuming constant rate of calcium carbonate deposition. From Table 1 the measured ratio in our clam is 0.68 ± 0.18, where the stated error is the 1σ counting error. This ratio corresponds to an age of 6.5 yr. At the 1σ level the uncertainty is -3, $+5$ yr.

This means that the growth rate of the long axis of this clam is about 4 cm yr^{-1} and the mass growth rate per animal (both valves) is about 20 g $CaCO_2$ per yr. We compare this with the growth rate we reported for an Atlantic Ocean deep-sea clam, *Tindaria callistiformis*[2], which reaches a length of 8.4 mm in about 100 yr for an average growth rate of 0.0084 cm yr^{-1}: about 500 times slower. Evidently the opportunistic nature of the clams living on the peculiar food source at the thermal vent permits a more rapid growth than the general ambient deep ocean floor environment. The same sort of opportunism has been reported for the deep ocean wood-boring clam, *Xylophaga* sp. by Turner[9]. She reported that 2 cm thick wooden planks, inserted in the North Atlantic ocean floor at a depth of 1,800 m by submersible and subsequently recovered, were almost completely devoured in 100 d by these clams.

Growth rates of clams on the deep ocean floor then appear to be primarily a function of the rate of food supply.

If we accept an age of 6.5 yr for this clam then we can interpret the radiochemical data used in establishing the upper age limits discussed above.

The $\Delta^{14}C$ of the clam is about 10% lower than the expected value from Pacific Deep Water. This can be ascribed to dilution of the deep water with old carbon supplied from the vents. Corliss *et al.*[1] determined the slope of the dissolved inorganic carbon to heat (via temperature) at 25×10^{-9} mol cal^{-1}. A temperature of 12 °C for the water in which the clam grew corresponds to an increase of total inorganic carbon of 250 μmol kg^{-1} above the Pacific Deep Ocean value of about 2,400 μmol kg^{-1} (ref. 10) (at a temperature of 2 °C). This is an approximately 10% increase which matches the observed ^{14}C decrease, if the vented carbon were totally devoid of ^{14}C.

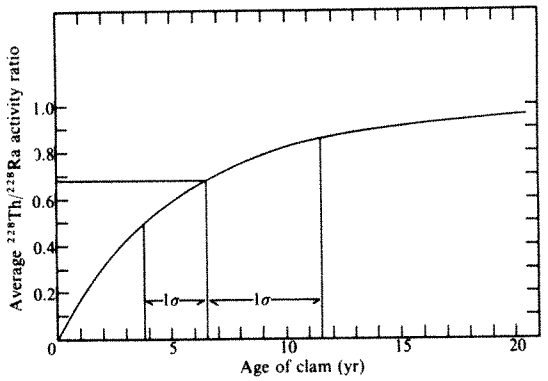

Fig. 1 The change in the average $^{228}Th/^{228}Ra$ activity ratio in a clam depositing a constant mass of calcium carbonate per unit time with a constant $^{228}Ra/Ca$ ratio and no initial ^{228}Th. A vesicomyid clam (Dive 713, Sample G3-2(L)) collected dead, but articulated, has an age at time of collection of 6.5 yr on the basis of this diagram.

Lead-210 appears to be sequestered by shallow water calcareous organisms more efficiently than radium by a factor of no more than two[7]. The $^{210}Pb/^{226}Ra$ ratio reported in Table 1 may then be assumed to be equal to or greater than the ratio in the ambient water in which the clam grew. As the shell is about 6.5 yr old, only a small amount of ^{210}Pb decay will have occurred, and the ratio provides a measure of the $^{210}Pb/^{226}Ra$ ratio in the water in which the clam grew. The deficiency of ^{210}Pb over that expected from the production from dissolved ^{222}Rn then provides a measure of the efficiency of the chemical removal process for ^{210}Pb from seawater in the region of the clam's habitat. The following material balance calculation can be made assuming a first order law for chemical removal as well as radioactive decay: Activity of ^{222}Rn (A_{Rn}) = Production rate of ^{210}Pb = Rate of radioactive decay of $^{210}Pb(A_{Pb})$ + Rate of chemical removal of ^{210}Pb. Therefore:

$$A_{Rn} = A_{Pb}\left(1 + \frac{\tau_{Pb}}{\tau_c}\right)$$

where τ_{Pb} (32 yr) and τ_c are the mean life of ^{210}Pb and the chemical removal residence time respectively. Referring to our calculation above involving ^{226}Ra and ^{210}Pb and using the same normalisation we obtain, as an upper limit, assuming equal fractionation of ^{210}Pb and ^{226}Ra:

$$\tau_c = \frac{32}{26 - 1} = 1.3 \quad \text{yr}$$

This implies that scavenging of ^{210}Pb is proceeding efficiently at least in the rock–water interface where the clam is growing. Corliss *et al.*[1] have already indicated how effectively seawater is stripped of Cu, Zn, Cd, Ni and U as the result of precipitation by H_2S within the "plumbing" of the thermal vent even before massive dilution with seawater occurs. Our results indicate that scavenging of ^{210}Pb, and possibly certain other elements that behave the same chemically, occurs even in the mixing zone between the hot water coming through the complex plumbing in the basalt and the ambient cold seawater of the ocean bottom. This is probably in the major part due to precipitation of ferromanganese oxides.

The initial $^{228}Ra/^{226}Ra$ value (0.057) in the clam is of the same order of magnitude as the ratio found in bottom water at GEOSECS station 263 from the South Pacific[11]. This concordance, however, may be largely fortuitous. If half of the radium in the bottom-most water in which the clam grew were derived from the leaching of basaltic rocks, the $^{228}Ra/^{226}Ra$ activity ratio of the bottom water would be about 0.34 which is markedly higher than the predicted value from the shell. In order to attain the measured value the length of time necessary to transfer the radium from its source to the surface would have to be 15 yr to

allow sufficient decay time for ^{228}Ra. On the other hand the high radon standing crop (6,000 d.p.m. per 100 kg) implies derivation from a secondary deposit of ^{226}Ra near the water–rock boundary. We cannot therefore identify the exact sources of the two radium isotopes based on the shell analysis.

Eucalyptus fruits in stratigraphic context in Australia

THE eucalypts are the outstanding group of Leptospermeae (subfamily Leptospermoideae of Myrtaceae) and of the whole Australian flora[1]. There are over 500 species of eucalypts, nearly all restricted to Australia. The origin of this remarkably diverse and successful genus has been a matter for speculation. The comparitively well known Tertiary palynological record is of little assistance in answering these questions, as spores and pollen have insufficient properties to identify the genus. Hence only the macrofloral record is taxonomically significant. Although Tertiary macrofossils[4] are abundant, the fossil record of *Eucalyptus* and even Leptospermoideae is poorly known[2,3]. The first unequivocal fossil gumnuts (*Eucalyptus* fruits), of indefinite age, were identified only recently from silicified floras near Woomera[5], in South Australia's present arid zone. These specimens were collected without reference to the stratigraphy. However, we have now collected specimens from similar silicified outcrops near Stuart Creek (Fig. 1), where their probable age may be deduced by correlation of the sediments with Tertiary sequences elsewhere in South Australia. *Eucalyptus* can now be placed in stratigraphic context.

Although Tertiary stratigraphy in South Australia is in a state of flux[7–12], we have been able to restrict the age range of the fossils discussed here (Fig. 2) to two possibilities within the Tertiary. The alternative correlations presented here permit an Eocene–Oligocene age on the one hand, and Miocene age on the other. All that could have been said previously was that the gumnuts were Mesozoic or younger.

We investigated the site in October 1978, and Fig. 2 shows a selection of gumnuts from the fossiliferous sediments. Other fruits and leaves present in abundance will be described elsewhere. The flora was collected from a sandstone-conglomerate sequence (Fig. 3, section 1) which disconformably overlies Aptian–Albian shales[6]. The basal conglomerate has clasts of quartzite, kaolinised shale, cream and grey cryptocrystalline silcrete and polished chert, jasper and quartz. Overlying this unit are cross-bedded, mature fine- to medium-grained sandstones. On a nearby ridge (Fig. 3, section 2), similar but unfossiliferous siltstones, sandstones and conglomerates disconformably overlie Cretaceous beds; the upper units here are representative of Tertiary sandstones north and south of Stuart Creek. The plant fossils are in a different facies, but the two sections are thought to belong to the same sedimentary cycle.

The Tertiary of South Australia in the Lake Eyre and Pirie-Torrens Basins, abutting the northeastern and southeastern margins of the area under discussion, has usually been divided into two formations of characteristically distinct lithology. Extensive sheets of coarse, mature sands and silts (Eyre Formation[7]), determined palynologically as Palaeocene to Eocene, are disconformably overlain by the rather immature fine sediments

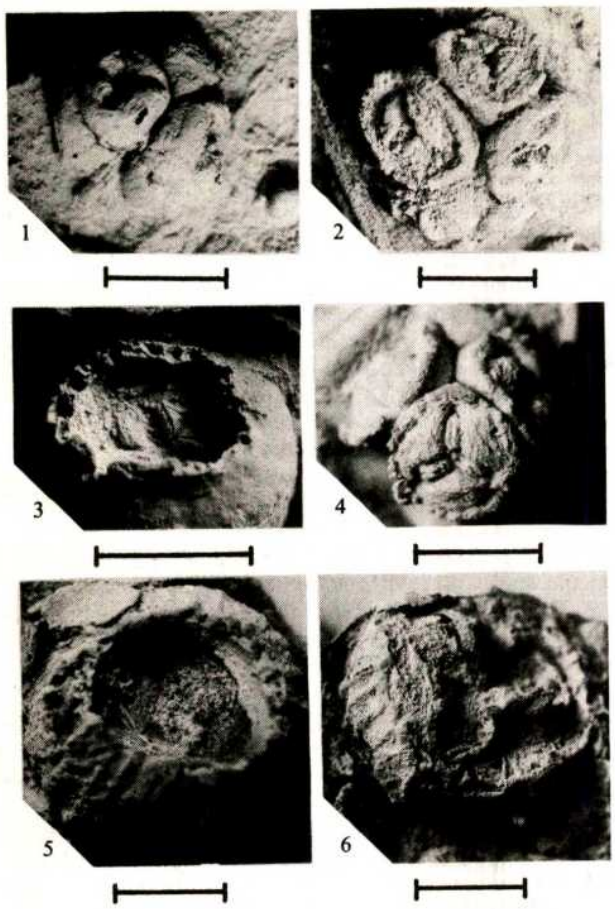

Fig. 2 Gumnut fossils from the Stuart Creek area. Scales represent 5 mm. Specimen 1: inflorescence of seven eucalypt-like capsules nearly sessile on a peduncle, each wedged against its neighbour but free at the summit which is flattened and exhibits three-valved loculicidal dehiscence. Specimens 2, 4: similar but another species, with raised rim, vertical disk and convex capsule dehiscent by three valves between which seed and chaff plugs sometimes remain. Specimens 3, 5: larger solitary fruits consistent with those of eucalypts, of maximum diameters much exceeding orifice diameter; with narrow raised rims, deep vertical disks and sunken capsules. One displays initial traces of three-valved dehiscence. Specimen 6: a ribbed eucalyptoid capsule with a flat summit and wide-gape three-valved dehiscence, the broken valve-tips apparently exerted.

of the almost equally extensive Medial Miocene, characterised by green clays and dolomites (Etadunna Formation[9]). The Medial Miocene age was also determined palynologically[7,10], from the basal Etadunna Formation and equivalents. Its upper strata contain vertebrates which are unlikely to be younger than Late Miocene (R. H. Tedford, personal communication 1973) so the unit is essentially Miocene.

The gumnut-bearing conglomerate contains rounded and sorted cryptocrystalline silcrete (siliceous duricrust) pebbles. Despite much mapping and drilling of Tertiary strata throughout South Australia and adjacent regions, no pre-Eocene silcrete of this type is known. Thus Tertiary sediments containing silcrete pebbles are probably Eocene or younger. However, the fossiliferous sediments are lithologically similar to the Eyre Formation in the adjacent basins. They could therefore represent the upper part of the Eyre Formation deposited contemporaneously with silicification, or a separate phase of sedimentation partly synchronous with or younger than this

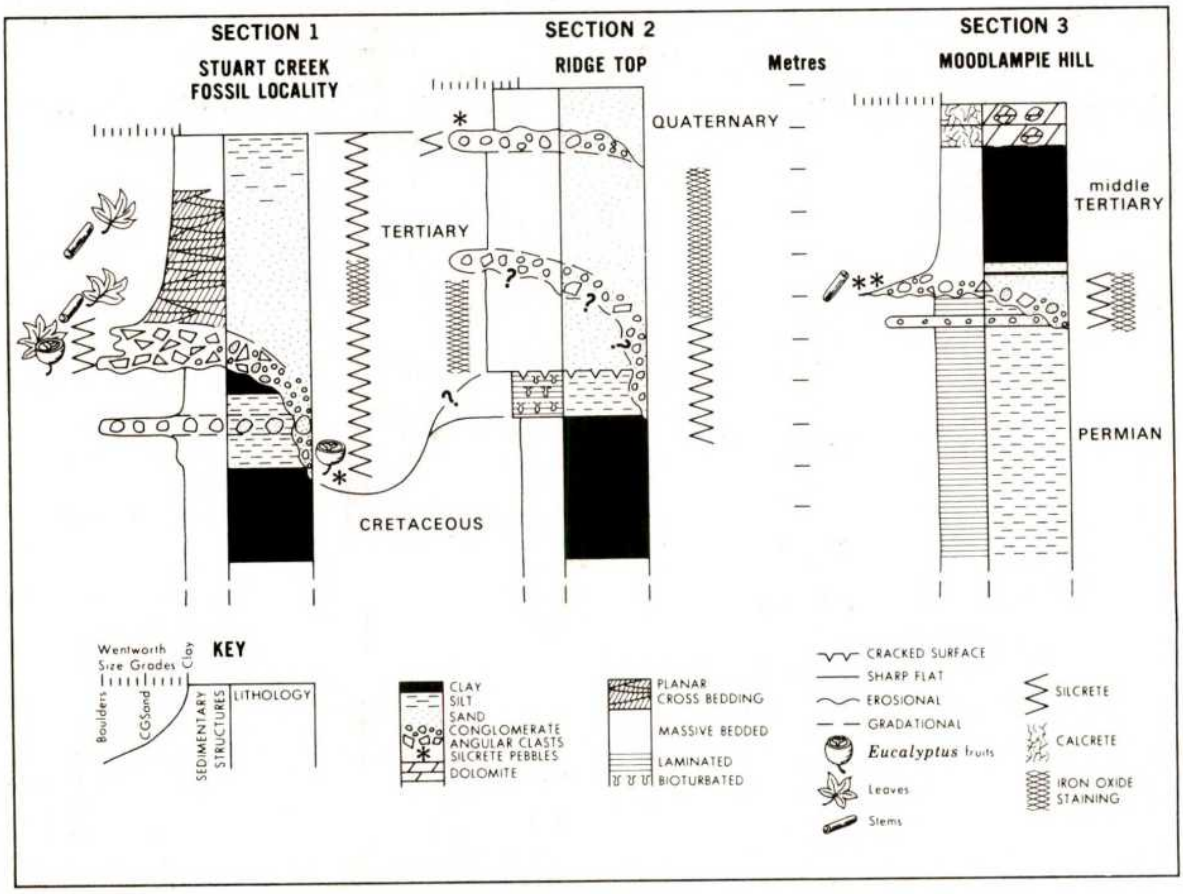

Fig. 3 Key stratigraphic sections. Tertiary sequences are disconformable on Cretaceous and Permian sediments and overlain by Pleistocene sand dunes in section 2.

Formation (of Eocene–Oligocene age) following a major interval of duricrust development.

On the other hand, at Moodlampie Hill (Fig. 1), conglomerate and sandstone intertongue with green clay and carbonate (Fig. 3, section 3) which we correlate with the Etadunna Formation of the Lake Eyre Basin. The conglomerate and sandstone, however, are similar to that at Stuart Creek, containing silcrete pebbles. A stratigraphic analysis of Tertiary sediments in the Billa Kalina area indicates that sediments at Moodlampie Hill and Stuart Creek may be facies equivalents (G.J.A. and R.B.F., in preparation). On this basis the *Eucalyptus*-bearing sediments would be Miocene. This concept presents problems in terms of currently accepted Tertiary stratigraphy[7,9,10], but is the simplest explanation in local terms. It opens the possibility of a late Tertiary age for at least part of similar extensive sandstone sheets elsewhere in the state, at present regarded as Eyre Formation.

Australian Palaeogene vegetations represented in southern and eastern near-coastal macro-floras were like those found today in equatorial and tropical wet regions, apparently being devoid of Leptospermeae[14,15]. Such conditions are supported by evidence from marine planktonic organisms, palynological data, and palaeotemperature measurements[16–19]. Kemp[16] has shown that in the Australian flora (excluding *Eucalyptus* which is not mentioned) there is no evidence of pronounced cooling until the Oligocene, and none of open vegetation reflecting seasonal aridity until the Miocene. Climatic zonation is apparently absent for the Eocene, but floral data suitable for reconstructing climatic zones are only available for this epoch, and even then derive mainly from southern Australia and the present coastal regions. By analogy with Quaternary climatic events one expects dry conditions and a zonal climatic distribution to have coincided with the periods of pronounced cooling in the late Eocene–Oligocene, and late Miocene. Hence xeromorphic vegetation and *Eucalyptus* in particular is unlikely to have radiated until at least the very late Eocene times. Xeromorphy, however, may have originated earlier, and there is some evidence for xeromorphy and cooling in the middle Eocene[16]. This is in keeping with the alternative ages suggested for the flora. In this context, the diversity of species in the silcrete floras will also be significant.

The gumnuts should have been readily preserved in the abundant coastal early Tertiary macrofloras, had they been even a minor component of the source litter. If they are Miocene or Oligocene, their absence from these Palaeocene–Eocene floras is readily explained, and their age is in accord with climatic interpretations[10]. If they are early to middle Eocene, then in Central Australia conditions must already have deteriorated from absolute mesicity, permitting upsurge of xeromorphic Leptospermeae so as to displace more mesic vegetation coastwards. This may imply drier conditions, suggesting rifting from Antarctica was sufficient to produce climatic changes influencing Australia, before the major cooling episode of the late Eocene to Oligocene.

We thank R. G. Wright of Newmont Pty Ltd for bringing to our attention the fossiliferous sediments at Stuart Creek. G.J.A., R.A.C. and R.B.F. publish with the permission of the Director General of Mines and Energy, South Australia.

Long-term recognition of father's song by female zebra finches

RECENTLY, attention has been directed at the question of how sexual imprinting, or the development of mating preferences, affects assortative mating within polymorphic species[1–3] and regulates the extent of inbreeding and outbreeding in a population[4–6]. It may be selectively advantageous for a young organism to learn individual characteristics of parents and/or siblings to avoid subsequent mating with kin as well as to avoid hybridisation by not mating with individuals that differ greatly from rearing partners[4–6]. I report here that adult female zebra finches (*Taeniopygia guttata*) can recognise the song of their own father after a period of early exposure followed by more than 2 months of separation while attaining sexual maturity.

The zebra finch is an Australian grassfinch (family Estrildidae), the young of which are totally dependent on parental care on hatching. Hatchlings are fed by both parents and do not leave the nest until about the third week[7]. Between days 30 and 40, the young leave (or are driven off by) the parents and form mixed flocks with other young finches. Sexual maturity is reached by 90 d (ref. 8). Thus, in early development (that is, before 40 d of age), females are exposed to the song of their father, and thereafter to the developing songs of male siblings that typically bear some resemblance to the father's song[9,10]. Adult male zebra finch song is highly variable between individuals in acoustic structure but relatively stable within an individual, thus providing a possible basis for individual recognition[11].

Females were hatched in rooms containing 12–21 breeding cages (82.0 cm long, 39.0 cm high, 30.0 cm deep) with one adult zebra finch pair per cage. (No other species were housed in these rooms.) At 35 ± 3 d after hatching, females were separated from their parents and housed in a soundproof room with other young female zebra finches in $82.0 \times 39.0 \times 30.0$-cm cages, each containing three females. At day 100 ± 3, each female was given a single 30-min simultaneous auditory choice test involving the song of her father and either the song of another adult male zebra finch that differed considerably from her father's song in acoustic structure, or the song of another adult male zebra finch that was similar to her father's song in acoustic structure. All male zebra finch songs used in the playback tests were recorded when the male was singing to his mate. No sounds other than the male's song were on the test tapes. Examples of the songs are shown in Fig. 1. The purpose of the first type of test (father's song compared with dissimilar song) was to assess the general capability of a female to recognise and show a preference for her father's song over that of a randomly chosen conspecific male that was not a close relative. The second type of test (father's song compared with similar song) assessed the specificity with which a female could distinguish her father's song from one that

Table 1 Choices of female zebra finches in simultaneous auditory choice tests

Test	*n*	Percentage responding	No. showing preference	Latency (s) Mean s.d.	Duration (s) Mean s.d.
Father's song compared with dissimilar song	31	77	17 $P<0.05$ 7	527 ± 616 $P<0.003$ 1,242 ± 768	1,069 ± 746 $P<0.001$ 401 ± 661
Father's song compared with similar song	21	86	9 NS 4	637 ± 661 NS 865 ± 806	942 ± 696 $P<0.02$ 503 ± 600

Statistical comparisons of preference scores were assessed using the χ^2 one-sample test (d.f. = 1), and latency and duration scores were assessed using the Mann–Whitney *U* test. All probability values are two-tailed.
NS, Not significant.

was similar. (Because song structure can differ considerably among individual males, a song similar to that of the father could be obtained only by recording either the female's uncle and/or male siblings, as related males tend to have similar songs due to early vocal learning[9,10].) Each female was tested only once in either the first or second test.

The rectangular test apparatus, housed in an anechoic chamber, was divided into two approach zones at opposite ends separated by a neutral zone, each zone being 70.5 cm long. Two loudspeakers were located outside the apparatus adjacent to each approach zone. Behavioural measures recorded were (1) latency of approach from a centrally located start box in the neutral zone to each approach zone, and (2) total time spent in each approach zone. A preference was recorded when a bird spent twice as much time in one approach zone as in the other.

The results are shown in Table 1. Female zebra finches recognised and significantly preferred the song of their own father to the dissimilar song of another male zebra finch. When confronted with the perceptually more difficult test of the father's song compared with a similar song, females still recognised their father's song. Although the tendency of females actually to prefer their father's song in the latter test was not statistically significant, those females that did prefer their own father's song had significantly longer duration scores than those preferring the similar song.

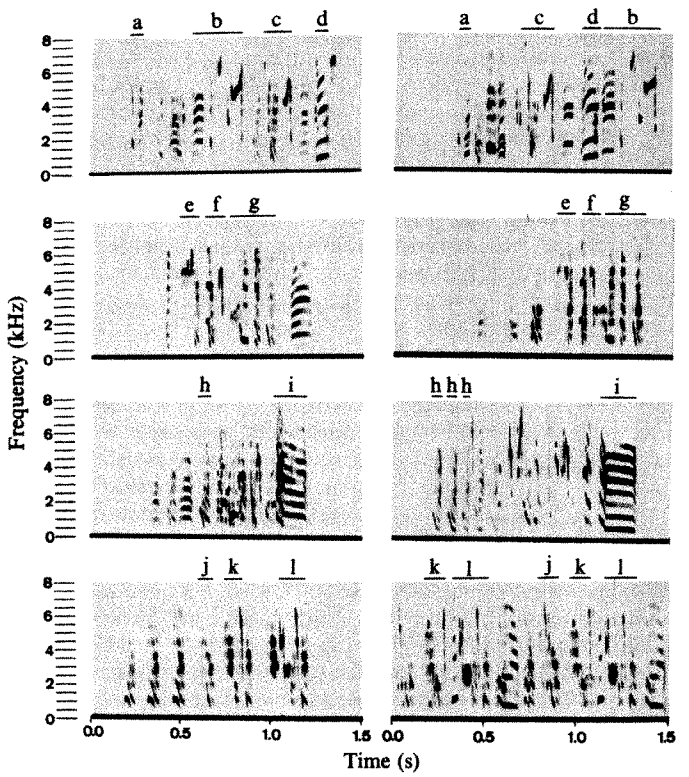

Fig. 1 Wide-band sound spectrograms of song phrases from eight different adult male zebra finches. Each pair (row) of sound spectrograms depicts two songs that are similar to one another and were uttered by two males that were closely related (either brothers or father and son). The common elements in these phrases are depicted above each spectrogram with a bar and a letter. The four spectrograms going down each of the columns are dissimilar from one another in acoustic structure and were uttered by unrelated males.

Thus, female zebra finches can recognise their father's song as a function of early exposure followed by a relatively long period of isolation from male song. These tests of approach behaviour do not necessarily reflect sexual motivation on the part of the female and therefore do not represent a demonstration of sexual imprinting as such. Rather, they demonstrate the extent to which females can recognise and discriminate their father's song from that of another conspecific male. Indeed, as females presumably do not mate with their fathers in nature, I would have predicted the outcome of these tests to be quite different had they been assessing sexual behaviour. Nevertheless, this study may have important ramifications regarding the study of sexual imprinting in general. The learning of both supra-individual (species) and individual characteristics during early exposure may, at the time of sexual maturity, influence an animal to (1) mate with its own species—a direct effect of learning supra-individual features—and at the same time (2) avoid mating with close kin—a direct effect of individual recognition. However, many studies[12–16] have shown that, in several species, individuals can identify conspecifics in advance of exposure to them and that embryonic and postnatal self-stimulation probably plays an important part in these and other instances of 'instinctive' preferences for species-typical stimuli[17,18]. Thus, it is conceivable that the role of imprinting in mate selection in nature may be of greater relevance to the learning of individual rather than supra-individual characteristics.

This work was carried out at the Department of Ethology, University of Bielefeld, FRG. I thank Klaus Immelmann for providing laboratory facilities, and G. Gottlieb, W. G. Hall, T. D. Johnston and R. W. Oppenheim for commenting on an earlier draft of the manuscript. The project was carried out while the author held an Alexander von Humboldt research fellowship and was partially supported by the National Institute of Child Health and Human Development.

Vertebrate and invertebrate predation intensity on freshwater zooplankton communities

PREDATION is widespread in the pelagic zone of lakes and both vertebrate and invertebrate predators are abundant and diverse in their feeding habits. Vertebrate predators are often size-selective and can virtually eliminate larger prey items[1–3]. These dramatic effects resulting from fish predation have led several workers to conclude that vertebrates contribute the largest percentage of the total predation intensity on freshwater zooplankton. Particular invertebrate predators, however, have also been shown to crop a substantial proportion of their prey populations[4–6]. I report here a study showing that invertebrate predation is more intense than vertebrate predation in the pelagic zone of Gull Lake, Michigan, with the first *in situ* evaluation of both types of predation on a single zooplankton prey assemblage. The significance of identifying major predation pathways in lakes is basic to many contemporary discussions of nutrient and energy flow as well as considerations of community structure and stability.

Gull Lake is a marl lake in southwestern Michigan which has undergone excessive nutrient enrichment[7–9]. The lake is 8.2 km^2 in area and 33 m deep. Following the development of a hypolimnetic oxygen deficit in 1966, there have been large changes in the zooplankton community. The present dominant species are *Bosmina longirostris, Cyclops bicuspidatus* and *Tropocyclops prasinus*. There are six species of *Daphnia* and moderate populations of *Diaptomus oregonensis* and *D. minutus*. Large copepods such as *Mesocyclops edax* and *Epischura lacustris* and one predaceous cladoceran (*Leptodora kindtii*) are present but rare. *Chaoborus* spp. are immature dipterans that live in the bottom sediments.

There are over 70 species of fish in Gull Lake; however, most of these are inshore or rare species. In 1952, smelt (*Osmerus mordax*) were introduced into the lake. By 1966, this species had become the dominant fish in the pelagic zone and it now represents 95–100% of all fishes taken with vertical gill nets in the central basin. This species schools by age class and is a stenotherm[10]. As eutrophication has progressed, smelt have become stressed, as their requirements for cold water and high oxygen concentration preclude their use of much of the anoxic hypolimnion and the warm epilimnion in summer. Immature fish are sometimes found in the upper few metres of Gull Lake but their appearances are highly seasonal. The population and predation dynamics of juvenile *Lepomis machrochirus* and *Labidesthes siccules* have also been studied[11].

Predation rates of fish were determined by multiplying densities of fish by the mean number of prey consumed per predator[12]. Densities of fish collected in 1973 are given in Table 1. Each fish was measured (length and weight), its age and sex determined and its stomach removed. Per cent stomach fullness was also recorded and all prey individuals were enumerated. To convert stomach content data to predation rates, values of stomach evacuation time and diel feeding periodicity were also determined (Fig. 1). While attempts to culture smelt were partially successful, it was not possible to obtain reliable feeding information in the laboratory and all results presented here are derived from field data.

Smelt have a definite seasonal pattern in their predation dynamics. In June, when the hypolimnion is well aerated, the fish consume mostly *Chaoborus* spp. larvae and some immature forms of *Tendipes* spp. and *Penteneura* spp. near the bottom. There is no evidence to suggest that smelt feed on the bottom of the lake in any season. In July, the fish are found higher in the hypolimnion and their feeding habits reflect their distribution patterns. Approximately 60% of the fish feed on *Daphnia* spp. and the rest consume insect larvae. In August, smelt consume more *Daphnia* spp. than insects. Generally, few copepods are eaten except in August. Burbidge found the same seasonal feeding pattern in 1965–66, except the feeding shift from insect larvae to crustacean zooplankton occurred later in the season[10]. His study included the year preceding the occurrence of the first oxygen deficit in the hypolimnion.

The determinations of *in situ* invertebrate predation were obtained using the fluorescence technique which is described in detail elsewhere[13,14]. Prey are stained with a fluorescent dye (Acridine Orange or Rhodamine B), placed in a grazing chamber and lowered into the lake. The chamber captures 9.8 litres of lake water including a natural assemblage of prey and predators. Simultaneously, the stained prey are released. Predation continues for 1 h, then all animals in the chamber are recovered and scored under a fluorescence microscope. A predator of a stained prey exhibits fluorescent appendages and/or gut tube. Invertebrate predators except *Chaoborus* spp. do not usually consume their prey whole; therefore, it is impossible to ascertain how much of a given prey was consumed, but many partially ingested prey are presumably eliminated from the lake. Mean predation rates, calculated as number of prey partially ingested per predator per time period, were determined in the summers of 1973 and 1974 and densities in 1972, 1973 and 1974.

The major cause of death for the Gull Lake zooplankton community (except insect larvae) is invertebrate predation

SS, sunset; MT, midnight; SR, sunrise; N, noon. *, No fish captured. The gill nets extended the total depth of the central basin. Several mesh sizes were used; however, only the 1.3-cm mesh captured substantial quantities of fish and only these results are reported. The nets were sampled at four time periods during each diel period. In June, the fish were mostly in the 6–15-m range with some individuals near the bottom of the lake. In July, as the surface water warmed, the fish were usually located at 11–20 m with an indication of downward movement at sunrise. In August, there was a notable lack of smelt in the hypolimnion during the period of oxygen depletion. For all dates, few fish were collected at noon. Sonar records have confirmed that fish are absent in the daytime when they probably migrate inshore[10].

Smelt as a population is less effective in cropping zooplankton prey than is *C. bicuspidatus*. Only night values and one invertebrate predator are included to enhance comparability. In addition, only prey species found in smelt stomachs are included. *C. bicuspidatus* consumes several other prey species and has a greater predation impact on the zooplankton community than indicated here[13]. Predation rates for *C. bicuspidatus* were averaged from several experiments in the field and laboratory and then multiplied by *in situ* predator–prey densities to determine number of prey consumed. This value was divided by *in situ* density to estimate % prey cropped, at the appropriate season, depth and time. Although *C. bicuspidatus* cannibalism occurred in all field experiments, there were not enough experiments with this species used as prey, thus, predation rates were difficult to calculate and % prey cropped values are rough estimates. *C. bicuspidatus* does not prey effectively on *Leptodora* and *Chaoborus* and these interactions were treated as not occurring. (*) NC, not consumed in this time–depth period. Densities of zooplankton in the water column were determined from samples by using water bottles or by making horizontal tows with a Clarke–Bumpus zooplankton sampler[7] and are given as organisms per m^3.

(Table 2). *Cyclops bicuspidatus* is an especially effective predator and, given its high densities, can substantially crop the rest of the community. This species possesses several adaptations that contribute to its efficiency[13]. First, the predator does not use vision to locate its prey. It feeds mostly by mechano- or chemoreception and perhaps selects prey more for their availability than for any other factor. Thus, this predator exhibits an effective density-dependent regulation on the other species. Second, it is highly cannibalistic at high densities, producing short self-damping loops in the ecological network (foodweb) which are stabilising to the ecosystem as well as producing effective regulation of its own population[13]. Third, several members of this species often consume a single prey simultaneously[13]. This group behaviour increases its predation efficiency and also has important ramifications for calculations of nutrient and energy flow. Fourth, *C. bicuspidatus* often nibbles on its prey and does not consume them completely, which makes accurate estimates of energy and nutrient flow difficult. With the fluorescence technique, the percentage of a prey individual consumed cannot be calculated as only the presence–absence and not amount of fluorescence is quantified[13].

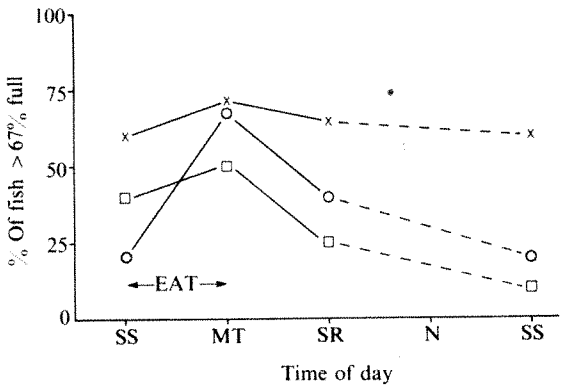

Fig. 1 Feeding periodicity based on stomach fullness shows that most smelt were full at midnight. From sunset to midnight, percentage of fish with stomachs at least 67% full increased markedly and then decreased until dawn to levels similar to those at sunset. Thus, smelt consume most of their prey from sunset to midnight. As fish are relatively empty at sunset and they apparently do not feed in the daytime, most of their feeding is concentrated in a 6-h period after sunset. Hourly stomach evacuation rates were calculated by subtracting the percentage of fish that were at least 67% full at dawn from those 67% full at midnight and dividing this value by six. For all dates (including several not shown) a mean value of 4.3% of the stomach contents was evacuated per hour or in a 6-h period ~25% of the stomach contents were evacuated.

Smelt consume a broad range of prey species and sizes and do not feed as a stereotyped size-selective fish as is suggested by contemporary dogma[15]. Although they may decrease populations of hypolimnetic zooplankton such as *Daphnia pulex* and *Chaoborus* spp., smelt probably have little effect on the myriad of interactions among most zooplankton species[13,16]. The net effect of smelt on several prey species may be positive as the smelt's high predation rate on insect larvae such as *Chaoborus* spp. (which are voracious zooplankton predators) may indirectly benefit the other prey more than the fish's direct predation harms them. *Chaoborus* spp. populations had decreased in 1973 to 70% of their 1966 densities. These animals are meroplanktonic and they find refuge against smelt predation in the bottom sediments. For Gull Lake, and undoubtedly many other lakes, invertebrate predators constitute the main predation pressure on a wide variety of zooplanktonic prey species. Because there have been so many technical problems in assessing invertebrate predation in the field before the development of the fluorescence technique, many workers have tended to over-emphasise the relative importance of fish predation[1,3,15]. Fish are definitely more effective predators on a per individual basis but invertebrate predators are disproportionately more abundant than fish. Thus, on a per population basis, invertebrate predators constitute the greatest danger to most zooplankton prey.

Joe Johnson and George Lauff are co-investigators on the smelt distribution studies. I thank Dian Gifford, Robert Conover and George Lauff for suggestions on the manuscript, Lynne Travers, Dian Gifford and John Wright for assistance with data analyses and manuscript preparation. The research was supported by NSF grant No. GB33337 and this paper is contribution number 379 from the W. K. Kellogg Biological Station.

Autoradiographic localisation of benzodiazepine receptors in the brains of humans and animals

THE benzodiazepine (BZ) drugs are used as anxiolytics, hypnotics, anticonvulsants and muscle relaxants. They are the most widely prescribed of all psychotropic drugs and seem to exert their action by binding to a specific receptor site on brain membranes[1,2]. This receptor appears to interact with neurotransmission mediated by γ-aminobutyric acid (GABA)[3–8]. Biochemical studies of BZ receptor distributions in brain reveal large regional variations[9,10]. An increase in resolution of localisation of BZ receptors would provide greater insight into mechanisms of actions of BZs. In this study, we report for the first time the light microscopic autoradiographic localisation of BZ receptors in mammalian central nervous system (CNS) and, to our knowledge, the first receptor autoradiography in human brain tissue. We observed striking variations in receptor densities in different areas which, in some cases, were species dependent.

The recently developed overall autoradiographic method[11] is based on *in vitro* labelling of receptors, since *in vivo* labelling results in low ratios of specific to nonspecific binding[12,13] and because it is desirable to use human postmortem tissues. Previously, *in vitro* labelling of receptors in brain sections and subsequent coating by nuclear emulsion for autoradiography has been feasible with irreversibly, or nearly irreversibly, binding ligands[14,15]. However, this approach has been unsatisfactory for most or all diffusible ligands[11,16]. Our method largely circumvents this problem by apposing a dry layer of emulsion against labelled tissue.

Briefly, brain tissues are placed on brass chucks and frozen in liquid nitrogen. Sections (4–6 μm) are cut in a cryostat microtome and thaw-mounted onto gelatin-coated slides. The slides are then dipped into 0.17 M Tris-HCl (pH 7.4 at 4 °C) containing 1 nM ^{3}H-flunitrazepam (87 Ci mmol^{-1}, NEN) to label the receptors. Some solutions contain 1 μM clonazepam to produce sections with nonspecific binding only. The incubations are performed at 4 °C for 40 min at which time the slide-mounted sections are washed for 2 min in buffer alone to reduce nonspecific binding. Routinely, we observed ratios of specific to nonspecific binding of at least 20 : 1 in preliminary biochemical studies. The binding was saturable with a K_D of 2.5 nM and was blocked only by other BZ drugs. The slides are then rapidly dried (for approximately 30 s) under a stream of cold air and flexible, emulsion (Kodak NTB3 emulsion, 1 : 1 with H_2O) coated coverslips are attached in the dark by glue to the slide at the end away from the tissue sections. After exposure for 2 weeks at 4 °C, the coverslips are gently bent away from the tissue sections, the latent autoradiograms developed, and the tissues fixed and stained with pyronine Y as previously described[11]. The assemblies are reapposed and then examined under the microscope.

Male Sprague–Dawley rats (180–250 g) and mice (20–50 g) (Jackson Laboratories) were used in animal studies. Human postmortem tissue samples were obtained at autopsy from a 50-y-old male (3 h post mortem; sudden death with no drug history) and a 22-y-old male (4 h post mortem; stab wound with no recent drug history) in cooperation with the Medical Examiners Office in Baltimore, Maryland.

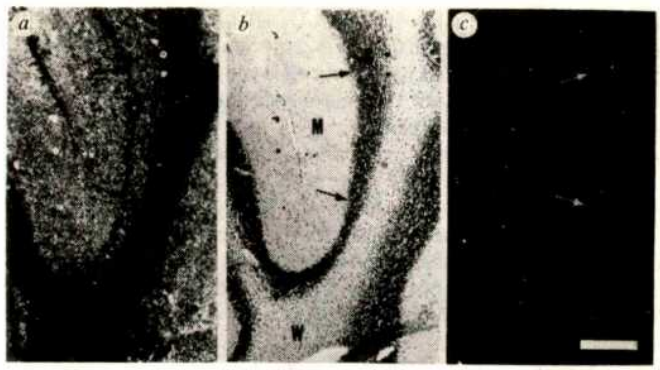

Fig. 1 Benzodiazepine receptors in human cerebellum. The darkfield photomicrograph in *a* shows the autoradiographic grain distribution over the tissue in *b*. Note the high density of receptors in the molecular layer (M) and in the granule cell layer (G), the reduced density in the Purkinje cell layer (indicated by arrows), and the absence of receptors in the white matter (W). The darkfield photomicrograph in *c* shows the blockade of receptor binding in an adjacent 4 μm section (brightfield not shown) due to the addition of 1 μM clonazepam. The conditions for labelling the receptors are outlined in the text. Sections were incubated with 1 nM ^{3}H-flunitrazepam in Tris-HCl (*p*H 7.4, 0.17 M) for 40 min at 4 °C, and washed for 2 min at 4 °C in the same buffer. The emulsion was exposed for 2 weeks at 2–4 °C. In tissues from two humans, actual grain densities (grains per 1000 μm^2 ± s.d., $n = 6$) for the cerebellar layers were as follows: molecular, 73 ± 9 and 79 ± 3; Purkinje cell, 67 ± 8 and 60 ± 18; granule cell, 77 ± 3 and 73 ± 8; and white matter 13 ± 7 and 8 ± 3. The corresponding values for rat cerebellum were 84 ± 17, 53 ± 5, 35 ± 4, and 6 ± 1. Grain densities in the presence of 1 μM clonazepam were 5–11 grains per 1,000 μm^2. The grain densities were counted in at least two preparations in six areas using a calibrated eyepiece grid. Scale bar, 500 μm

In human tissues, we examined the autoradiographic distribution of BZ receptors in cerebellar and cerebral cortical areas including the superior frontal, the precentral and the calcarine areas of the cortex. In all of these areas there was a striking absence of BZ receptors in the subcortical white matter. In the cerebellum, there was a high density of receptors in association with both the granule cell layer and the molecular layer. There was a slight reduction in receptor density in the Purkinje cell layer (Fig. 1; see also Table 1). In the cerebral cortical areas, there were variations in autoradiographic grain densities. The receptor density in the calcarine cortex, for example, was highest in Brodmann[17] layers III, IVA and IVC (Fig. 2, Table 1). This striking variation emphasises the value of this technique in the study of the neuroanatomical aspects of receptor localisation.

The absence of BZ receptors in white matter and the regional variations in receptor density were also observed in brain tissues from rats and mice. In the cerebellum there was a similar high density of BZ receptors in the molecular layer but, compared with the human tissues, there was a markedly reduced level of BZ receptors in the granule cell layer (see Table 1). In the rat and mouse cerebral cortex, there were also variations in the different cortical layers. In the rat, the autoradiographic grain densities in the caudate-putamen and septum were lower than in the cortex and fairly evenly distributed over these structures, although still of a fairly high density. In these same tissue sections we observed an elevation of BZ receptors in and near the islands of Calleja in the ventral forebrain (Table 1).

A striking regional variation in BZ receptors was observed in the rat cervical spinal cord. As in other areas, there were no receptors in the white matter areas, but high levels of receptors were found in laminae II, III, IV, and X while there was a much

0028–0836/79/310393—03$01.00

© Macmillan Journals Ltd 1979

lower receptor density in lamina IX which contains the motor neurones. Finally, we observed BZ receptors highly localised to the inner plexiform and ganglion cell layers of the rat retina. The grains were also present to a lesser extent in the nerve fibre and inner nuclear layers (Table 1).

While one cannot rule out some glial localisation of receptors, the striking absence of BZ receptors in white matter and its restriction to grey matter areas are consistent with the notion that the receptors are localised to neurones. The striking variations of receptor densities within grey matter areas suggest that the binding site is not simply a common constituent of all neuronal membranes. Earlier suggestions that the receptors are localised to glial cells[19] are difficult to reconcile with the observed interactions with the neurotransmitter GABA[3-8] and recent reports that these receptors are reduced in *nervous* mice[19-22]. In addition, we did not observe binding of ^{3}H-flunitrazepam to blood vessels of any size, although the ependymal cell layer around the fourth ventricle showed significant binding of ^{3}H-flunitrazepam which was not displaced by 1 μM clonazepam and was not apparent with controls for positive chemography.

There have been many biochemical and electrophysiological studies showing an interaction of BZ receptors with GABA receptors[3-8]. Our autoradiographic localisations of GABA receptors have not revealed a simple correlation between BZ receptors and GABA receptors labelled with ^{3}H-muscimol in the cerebellum. We did not observe a high density of ^{3}H-flunitrazepam binding sites in and around the Purkinje cells as was observed previously with ^{3}H-muscimol[23]. In fact, our initial studies with ^{3}H-muscimol and ^{3}H-GABA in the rat reveal higher receptor levels in the granule cell layer than in the molecular layer (J. M. Palacios *et al.*, in preparation). When GABA (200 μM) was present during the labelling of the BZ receptor in the rat cerebellum, autoradiographic studies showed that the increases in ^{3}H-flunitrazepam binding occurred in the same proportion in all layers. Our observed high density of BZ receptors in the dorsal horn of the spinal cord does partially overlap with the distribution of glutamic acid decarboxylase (GAD) immunoreactivity in these areas[24]. These overall results are compatible with the observed interaction between BZ and GABA receptors but further suggest that BZ receptors are more widely distributed for additional functions and that only a subpopulation of GABA receptors interact with benzodiazepine receptors.

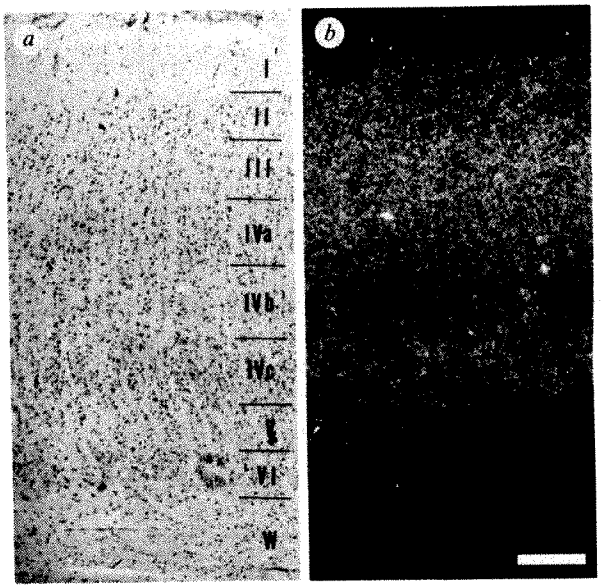

Fig. 2 Benzodiazepine receptors in human calcarine cortex. The darkfield photomicrograph in *b* shows the autoradiographic grain distribution over the tissue in *a* where the cortical layers (I–VI) and the subcortical white matter (W) are labelled. The receptor density varied in the different layers (for example elevated in Brodmann[17] layers III, IVA, and IVC) and was relatively negligible in the white matter. Adjacent sections labelled in the presence of 1 μM clonazepam showed a loss of the autoradiographic grains with a resultant grain density similar to that shown in *a* and *b* for white matter (not shown). Experimental details are given in the text and in the legend to Fig. 1. Scale bar, 250 μm.

Table 1 Relative density of benzodiazepine receptors in selected brain regions

Region	Relative grain density
Rat:	
Cerebellum	
Molecular layer	+ + +
Purkinje cell layer	+ +
Granule cell layer	+ +
White matter	0
Striatum	+
Cerebral cortex (frontal)	+ + to + + +
Corpus callosum	0
Islands of Calleja	+ + + to + + + +
Spinal cord	
Laminae I, VIII, IX	+ to + +
Laminae II, X	+ + +
Laminae III, IV, V, VII	+ + to + + +
Retina	
Inner plexiform layer	+
Ganglion cell layer	+
Human:	
Cerebellum	
Molecular layer	+ + +
Purkinje cell layer	+ +
Granule cell layer	+ + +
Calcarine cortex	
Layers I, II, IVb, V, VI	+ +
Layers III, IVa, IVc	+ + +

Tissues were processed and examined as described in text and Fig. 1.

The wide distribution of BZ receptors through the CNS contrasts with the much more restricted localisations of other receptors, such as the opiate receptors[25]. The cholinergic muscarinic receptors are similarly widespread but are more localised to telencephalic areas than brainstem areas[26]. Interestingly, high densities of muscarinic receptors were demonstrated in and around the islands of Calleja[26] which is similar to what we have observed in this study.

The species differences in receptor distribution in the cerebellum and possibly in other areas suggest that that extrapolation of results from pharmacological studies with animals to humans must be done with caution. Administration of benzodiazepines has striking clinical effects as mentioned above. While the widespread distribution of BZ receptors in the CNS suggests caution in correlating anatomy and drug action, it is tempting to associate anxiolytic action roughly with receptors in cortical areas[27] and muscle relaxant actions with spinal cord receptors.

We thank Dr Mark Molliver for useful discussions, Mrs Naomi Taylor and Ms Mary Conrad for technical assistance and Mrs Carol Kenyon and Ms Princie Campbell for secretarial help. This work was supported by PHS grants MH25951 and MH00053 and PHS postdoctoral fellowship MH07624 to W.S.Y.

Central remyelination restores secure conduction

ONE of the outstanding characteristics of multiple sclerosis and other clinical and experimental diseases associated with demyelination, is the tendency to remit. Although there is good evidence that an important cause of functional loss in such conditions is conduction block produced by the selective destruction of the myelin sheath[1], the mechanisms underlying remission are unknown[2]. It has long been recognised that in certain experimental lesions demyelinated central axons can be remyelinated by the normal myelin-forming cell, the oligodendrocyte[3]. The new sheaths are, however, abnormally thin and short and it is not known whether they are capable of restoring conduction. A previous investigation was inconclusive[4]. Because of the physiological and clinical importance of this problem, we have now examined conduction serially through the lesion induced by the direct microinjection of lysophosphatidyl choline (LPC) into the cat spinal cord[5]. This lesion has the advantage that the phases of active demyelination and remyelination are well separated, thus permitting a reasonable correlation of the morphological with the physiological changes. We have found that secure conduction is restored with remyelination.

Pairs of platinum or stainless steel stimulating electrodes were permanently implanted at two extra-dural sites over the dorsal columns (usually L1 and L3) in five cats. Recordings were made from the saphenous nerves with stainless steel needles which were accurately repositioned at each session with the aid of tattoo marks. For the recording sessions the cats were anaesthetised with Saffan (Glaxo), paralysed with gallamine triethiodide, intubated and artificially respired to maintain the end-tidal CO_2 level at 4%. Rectal temperature was maintained at 37 ± 0.5 °C. Differential recordings were made with unity-gain cathode followers and Devices pre-amplifiers. The stimulus thresholds were re-determined at each recording session and remained fairly constant over many months. The responses to stimuli at 4 × threshold were averaged ($n = 64$; Biomac 1000) from each nerve after stimulation at each site. Occlusion of the response from the rostral stimulating site as the stimulus strength at the caudal site was increased established that the fibres contributing to the caudally evoked response included those stimulated at the rostral site. The refractory period of transmission[6] (RPT) was determined from the averaged response to the second of two stimuli at 4 × threshold at a range of interstimulus intervals[7]. Recordings were made for 1–2 months before and up to 4 months after inducing the lesion. When the responses were stable at successive sessions, injections of 1.5–2.0-μl LPC (0.8%) were made into the dorsal columns. At the end of the experiment the lesions were studied by light and electron microscopy following glutaraldehyde (4%) fixation by perfusion or immersion.

The sequence of morphological events in the LPC lesion has already been reported[5] and is summarized in Fig. 1. At 3 and 7 days there was extensive demyelination and at these times the amplitudes of the compound action potentials elicited from the rostral stimulating site were markedly reduced in contrast to the control response, which remained unchanged. The conclusion that conduction in many fibres was blocked by demyelination was confirmed by the observation of a large positivity in antidromic recordings made acutely at the lesion site after 7 days.

Remyelination had begun by 14 days, and there was a coincident increase in the number of fibres contributing to the rostrally evoked response (Fig. 1). Over the succeeding weeks the thickness of the new sheaths and the response amplitude increased in step until approximately 81 days, when both stabilised. These later recordings were similar in form to those made before the injection but had a reduced amplitude attributable to the loss of some fibres by Wallerian-type degeneration. There was little change in the latency of the long-term responses. The control response remained constant throughout.

A measure of the security of conduction was obtained from the RPT. In normal fibres, the maximum observed RPT was 1.2 ms. At 3 and 7 days, the range of RPTs of the few fibres still conducting was normal, in keeping with the presence of some histologically unaffected fibres. However, at 14 days, when the compound action potential had increased in size, the majority of fibres had prolonged RPTs (up to 4 ms). Thereafter, the RPT decreased progressively and was normal by 81 days. The RPTs of the control response remained normal throughout.

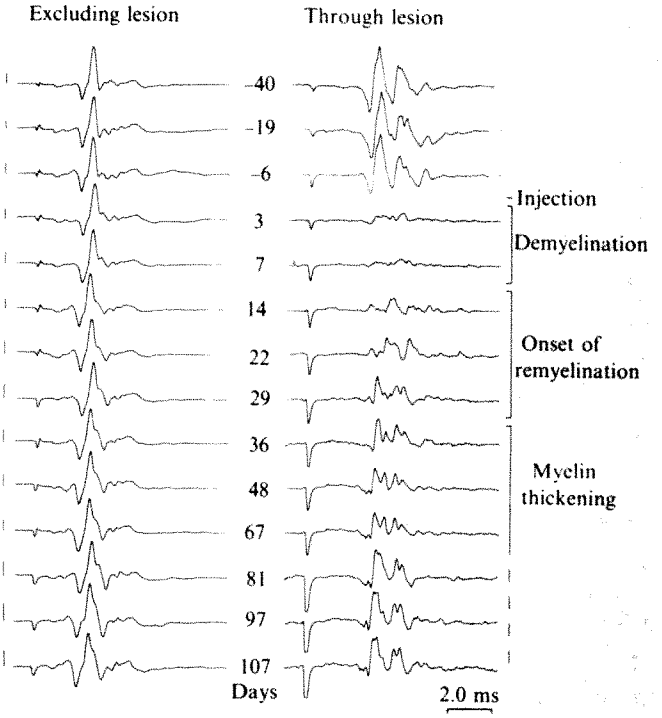

Fig. 1 Saphenous nerve compound action potentials recorded at different times during the development of a focal demyelinating and remyelinating lesion in the dorsal column. To compensate for variables at the recording site the gain on each control response has been adjusted so that their peak-to-peak amplitudes are equal. The corresponding rostrally evoked response has been adjusted by the same factor; each was recorded at 3.3 times the gain of the control. Vertical calibration bar for each recording, 10 μV.

These experiments have established that conduction begins to return to previously blocked fibres at about the time remyelination begins. Conduction is at first insecure but as the sheaths thicken the RPTs progressively return to normal despite the fact that the internodes remain both thinner and shorter than normal (ref. 5 and W. F. B. and Murray, unpublished observations). The nodal and paranodal morphology is, with few exceptions, normal (W.F.B., unpublished observations). The observation that conduction returns at the same time as new myelin sheaths are formed suggests that it is saltatory in nature. This interpretation is consistent with the return of the RPT to normal. The techniques now available cannot establish whether there is a preceding phase of continuous conduction as in demyelinated[8] and amyelinated[9] peripheral axons.

The restoration of conduction by remyelination is probably of only limited importance to the remissions and delayed evoked potentials[10] seen in multiple sclerosis, as remyelination is limited in this disease[11]. However, it will probably be more important in mediating the recovery seen after demyelination induced by certain compressive lesions of the spinal cord which, at least experimentally, are associated with the formation of new myelin sheaths with similar characteristics to those found in the LPC lesions[12,13]. Although the reason for the striking differences in the extent of remyelination between different types of lesion is unknown[14], the observation of restoration of secure conduction by remyelination suggests that further investigation of techniques for promoting central remyelination would be well worthwhile[15].

The optical mechanism of the eye of *Limulus*

THE compound eyes of many marine and some terrestrial arthropods have smooth surfaces with no convex curvature to the facets. This means that image formation by ordinary spherical refraction is impossible. Nevertheless, apposition eyes of this kind form images behind each surface facet[1,2] (Fig. 1*b*) and the question has repeatedly arisen as to how these images are produced. Exner chose the king crab, *Limulus*, as providing the definitive example of such an eye, and from a mixture of observation and theory came up with the idea of a lens-cylinder,

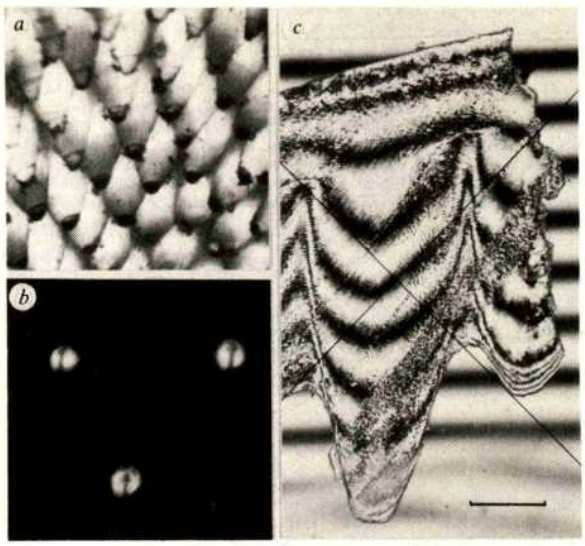

Fig. 1 *a*, Inner surface of the cornea of *Limulus polyphemus* showing the cleaned tips of the crystalline cones. *b*, Images photographed at the cone tips. The object was a black arrowhead on a light circular background whose diameter subtended 8.9° at the eye. The preparation was immersed in seawater. Average separation of the cone tips is 255 μm. *c*, Appearance of a thin parallel-sided frozen section through the centre of a cone using shearing interference optics and a fringe-field eyepeice (Vickers). The whole fringe pattern is visible on the right, with the zero-order (black) fringe at the top. This fringe reappears in the specimen under the crosswires, and it can be seen that in the cone centre it is displaced by just over 4 wavelengths ($\lambda = 542$ nm) and that away from the cone axis this displacement decreases roughly parabolically to about 2 wavelengths. The refractive index (n) at any point can be found from the path difference (PD):

$$PD = m\lambda = t(n - 1.334), \text{ or } n = m\lambda/t + 1.334$$

where m is the number of wavelengths by which the appropriate fringe is displaced and t is the section thickness (13.0 μm). The tip of the cone overlaps the microscope's second image, and the last fringe is lost.

a flat-ended optical device in which the refractive index decreases from the central axis to the periphery in a roughly parabolic manner[1]. This arrangement will form an image (Fig. 2*a*), and devices of this kind have actually been manufactured[3,4]. Exner's theory has long been considered to be the correct account of image formation in this type of eye[5]. However, Levi-Setti, Park and Winston[2] have recently produced a fundamentally different explanation of image formation in *Limulus* eyes (Fig. 2*b*). This was based on the idea that each optical element, or crystalline cone, concentrated light by reflection, not refraction, and that it was the shape of the crystalline cone's reflective surface, and not its internal refractive index gradient, that led to the image-forming properties of the structure. This principle had already been used in another optical device, the 'ideal light collector' (ref. 6) which was invented as a tool for concentrating faint radiation. In this report I discuss the two suggested optical mechanisms for the eye of *Limulus*, and present evidence from interference microscopy that Exner's theory is probably the correct one.

One difference between the refracting (Fig. 2*a*) and reflecting (Fig. 2*b*) explanations is that the former predicts an inverted image and the latter an erect one. (It is, in fact, a design feature of the ideal light collector that the parabolic profile on the left focuses light onto the lower tip of the right profile, thereby excluding light making larger angles with the axis than that shown in the diagram[6].) The images seen at the tips of the cones in *Limulus*, are, in fact, inverted (Fig. 1*b*).

A second difference is that in the refracting mechanism there should be a relatively gradual refractive index change from centre to periphery of each cone, whereas in the reflecting

mechanism this should be abrupt, so that total internal reflection can occur at the interface. The exact form of the gradient in a refracting lens-cylinder was not known to Exner[1], but was worked out later by Fletcher, Murphy and Young[7]. Their solution, for a structure of length F and central refractive index n_0 is

$$n = n_0 \operatorname{sech}(\pi r/2F) \quad (1)$$

where n is the refractive index at a radial distance r from the axis of the cone. Some of these curves, for different values of F, are plotted in Fig. 3*a*.

It is possible to determine which prediction is correct by interference microscopy. An interference microscope splits light from a single source into two beams, one of which passes through the specimen and the other through the bathing medium. These beams are recombined in the objective, and where the optical path-length through the specimen differs from that in the medium, interference occurs, resulting in colours in white light, or distinct dark and light fringes in monochromatic light. In the microscope I used, the interference version of a Vickers M41, there are two distinct ways of viewing the specimen. It can be seen against a uniform background with a constant path difference across the field of view, in which case optical inhomogeneities within the specimen show up as a series of fringes representing 'contour lines' of refractive index, provided the specimen is of uniform thickness. Alternatively, a fringe-field eyepiece incorporating a quartz wedge can be used; this produces a series of visible fringes in the field of view, and the effect of a specimen is to displace these in such a way that the refractive index profile through the section is depicted directly as the pattern of fringe distortion. The first method is capable of giving accurate local measurements of refractive index, but the latter is much more useful for demonstrating the shape of the whole refractive index profile. From their studies Levi-Setti *et al.*[2] and Carricaburu[8] concluded that the cone itself had a high and fairly uniform refractive index, but was surrounded by a lower refractive index, less homogeneous matrix, and that the transition from cone to matrix was abrupt enough for total internal reflection to occur.

Figure 1*c* shows otherwise. This shows a frozen section, 13.0 μm thick (the exact thickness was determined from path difference measurements in two media of different refractive index, water and air in this case) taken along the axis of a cone from an excised eye, kept in seawater containing 1% formaldehyde as a preservative. The eye used for sectioning retained the same image-forming properties as freshly excised material, and so was presumably optically identical. The photograph shows a series of fringes that have a roughly parabolic appearance, curving only gently in the centre of the cone, but increasingly more steeply into a trough that represents the centre of the inter-cone matrix. There is no sudden boundary, and when the fringe pattern is translated into a refractive index profile, this is found to coincide very closely with that of an Exner lens cylinder[1,7] 600 μm long (the actual length of the inhomogeneous

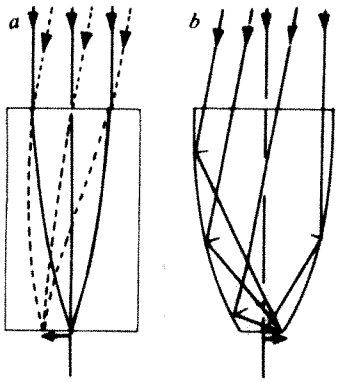

Fig. 2 Optical mechanism of *Limulus* crystalline cones. *a*, The refracting mechanism of Exner[1]; *b*, total internal reflection mechanism of Levi-Setti, Park and Winston[2]. Scale bar, 100 μm.

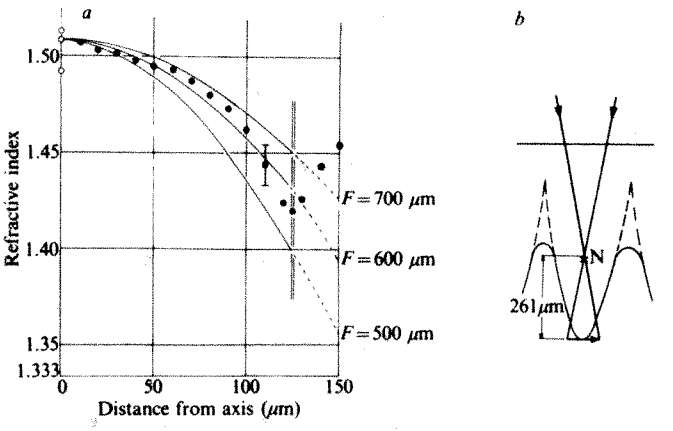

Fig. 3 *a*, Refractive index gradient from centre to periphery of a single cone. The filled circles are means of six measurements made on each side of the three principal fringes in Fig. 1*c*. The range of the measurements is shown for the most variable point by the vertical bar. Open circles on the ordinate are central refractive indices of three different cones. The continuous curves are three solutions of equation (1), with $n_0 = 1.51$, and three values for F. Excluding the outer cornea, 100 μm thick, which does not distort the fringes and is optically homogeneous, the axial length of the 'lens-cylinder' part of the cone (F) is about 580 μm. The theoretical curves (dashes) continue to fall indefinitely, but the points begin to rise again at the double vertical line as one cone ends and the next beings. *b*, The location of the nodal point (N) in a cone, based on image magnification (Fig. 1*b*), is indicated by the intersection of image-forming rays. The small cross indicates its position as predicted from equation (2).

portion of the cone is 580 μm) with a central refractive index of 1.51 (Fig. 3*a*). Note that equation (1) contains no arbitrary constants; the fit of theory and data thus means that the profile shown in Figs 1*c* and 3*a* must give an image at the cone tip.

By way of confirmation, the focal length of the cone (f, defined as image size/angle in radians subtended by an object at infinity) also coincides with that predicted by Fletcher *et al.*[7] They give

$$f = 2F/\pi n_0 \quad (2)$$

which for $F = 600$ μm and $n_0 = 1.51$ gives a value for f of 253 μm. The measured value, obtained directly from the images shown in Fig. 1*b*, was 261 μm. The receptor clusters, situated just beneath the cone tip, have a diameter of about 35 μm, so that for $f = 261$ μm each cluster should subtend an angle of 7.7°, which is almost identical to the inter-ommatidial angle in the centre of the eye.

These three observations, the inverted image, the existence of the refractive index profile required for a refracting lens-cylinder and the finding that the focal length is just what this model would predict, must be taken to mean that Exner's enlightened guess was quite correct (Fig. 2*a*) and that the reflection model (Fig. 2*b*) is not the way in which the images are produced.

I thank Frances Burton for cutting the sections. Thomas Collett, Kuno Kirschfeld and Jochen Zeil read and made helpful comments on the manuscript, which was typed by Sally Byatt. I acknowledge financial support from the SRC.

GTP hydrolysis in intact rod outer segments and the transmitter cycle in visual excitation

THE light-sensitive dark current of vertebrate retinal rods is the main metabolic load on the receptor cells, turning over the cytoplasmic Na^+ every 1–6 min (refs 1–4) and the cytoplasmic ATP as often as every 20 s (refs 5, 6). However, a second process in the rod outer segment (ROS), the transmitter cycle, probably demands metabolic free energy during visual excitation. Photons absorbed in the intracellular rod disks reduce the dark current traversing the nearby plasma membrane by altering the cytoplasmic level of a diffusible intracellular transmitter substance[7–10] that may be free Ca^{2+} (refs 11–14). As tens to thousands of transmitter particles must be released and removed in a single photon response[15–17], the transmitter cycle should cause fast metabolic events in ROSs even when they are isolated from those parts of the receptor cells that sustain the dark current. We report here that light causes ROSs to destroy GTP and form GDP at a rate sufficient to meet the predicted requirement of the transmitter cycle. Briefly, ROSs with intact plasma membranes and normal cytoplasmic nucleotide content were isolated within a few seconds from live frog retinas; aliquots of the ROS suspension were exposed to flashes of light, and the cytoplasmic levels of ROS nucleotides monitored as a function of time. The experimental procedure permits changes in cytoplasmic nucleotides in ROS to be distinguished from those involving nucleotides in the suspending medium or bound to rod disk membranes that are not enclosed within an intact plasma membrane.

Rana pipiens or *Rana catesbiana* were dark adapted for 4 h and their retinas removed by dissection in oxygenated Ringer solution containing 10 mM glucose. All operations were done under IR illumination with the aid of image converters. Four retinas were placed in a plastic syringe barrel of internal diameter 1.44 cm in 1.5 ml of frog Ringer solution containing 0.9 mM Ca^{2+}, 10 mM glucose and 0.5 mM phosphate. Potato apyrase (Sigma), 1 U ml^{-1}, was added to split extra cytoplasmic nucleoside di- and triphosphates to monophosphates. *p*H was buffered to 7.1 with PIPES and the retinas were slowly tumbled with a stream of O_2 bubbles. After 3 min, a cylindrical Kel-F spindle 0.89 cm in diameter was dropped axially into the syringe barrel. The spindle turned at 3,900 r.p.m., agitating the retinas in a hydrodynamic shear for 10 s. The spindle was withdrawn and the contents of the syringe expelled with a rubber piston through a coarse platinum mesh and a nylon mesh with 37-μm holes on a side. The filtrate contained ROSs, rod cell nuclei and a few erythrocytes (Fig. 1*a*). When a sample of the suspension was made 10 μM in didansyl cystine (DDC) and examined under 365 nm excitation, many non-fluorescent outer segments with intact plasma membranes were seen (Fig. 1*b*)[18]. When such suspensions were fractionated on metrizamide density gradients, the DDC-staining ROS held less than 10% as much acid-extractable nucleotides per unit particle volume as did the unstained ROS (W. E. R. and W. A. H. in preparation). As 20–35% of the ROS in the suspensions were DDC-excluding the contribution of nucleotides bound to DDC-staining rods to our measurements could usually be neglected.

ROSs were separated from their suspending medium by centrifugal filtration through silicone oil[19]. Aliquots (100-μl) of the rod suspension were layered into 1.5 ml Eppendorf centrifuge tubes previously loaded with 0.1 ml of 0.6 M $HClO_4$ brought to density 1.06 with glucose and overlaid with 0.4 ml of a mixture of Dow–Corning types 555 and 200 silicone fluids of density 1.04 at 25 °C. At selected times a loaded tube was placed in an Eppendorf centrifuge and its contents exposed to a 2-ms flash of 520–590 nm light which reached the rod suspension through the translucent polyethylene tube cap. After a timed delay the centrifuge was run for 10 s at 16,000*g*. The ROSs and other particles in the upper aqueous layer passed into the lower $HClO_4$ layer and became packed as a button. Control experiments with ROSs suspended in Ringer solution containing tritiated water showed that the total volume transferred between the aqueous layers was about three times that of the particles. Particle transfer between the upper and lower aqueous layers was complete within less than 4 s of the start of centrifugation. The lower aqueous layers containing soluble constituents of the cellular particles were neutralised with KOH and

Fig. 1 Photomicrographs of bullfrog ROS suspensions prepared as described. Many rod cell nuclei (n) and a few erythrocytes (e) are present. The nucleoside phosphates are more than 10 times as abundant in ROSs that do not stain with DDC than in those that do. *a*, Dark field, 546 nm illumination; *b*, DDC fluorescence, excited at 365 nm and observed at wavelengths greater than 450 nm (see ref. 18).

K_3PO_4 and analysed by high-pressure liquid chromatography on Partisil 10-SAX (Whatman) with a 40-min gradient of KH_2PO_4, *p*H 3.5, running from 0.05 M to 0.75 M. Nucleotide yields were expressed as mol per l of non-DDC-staining rod water. The detection limit for A and G nucleotides was about 60 μM.

The only nucleotides detected in the extracts were mono-, di-, and triphosphates of adenosine and guanosine, and a trace of UTP. Figure 2*a* shows the adenine and guanine nucleotides of a suspension that was sampled over a 5-min period in darkness after collection from the live retinas. There was a slow loss of all forms of A and G that could be shown in control experiments to

be due to leakage from ROSs into the suspending medium. Ouabain (50 μM) added to the ROS suspension had no detectable effect on the loss of ATP or ADP in darkness: no ATPase activity seemed directed by ROSs towards their own internal ATP. Guanosine phosphates were usually more abundant than those of adenosine. The total nucleoside phosphate content of ROS cytoplasm (including bound forms released during the 5–10-min extraction period in $HClO_4$) exceeded 5 mM, as previously reported[5]. The triphosphate:diphosphate ratios of the adenine and guanine systems differed widely, that of the G system being much lower even with stringent precautions against exposure of the ROSs to light. The ATP : ADP ratio was very sensitive to the oxygenation of the retinas before separation of the ROSs, dropping from 4–7 to about 1 if the O_2 bubbles were stopped for 1 min before the ROSs were sheared from the retinas.

When ROSs were illuminated with flashes that bleached 1% of their photopigment, there was little effect on the levels of ATP or ADP (Fig. 2*b*). The extractable GDP fell within 4 s by 1.0 ± 0.1 mM ($n = 7$). Then about two-thirds of the extractable GTP disappeared in 20 s and an equal amount of GDP was formed. After 30 s there was a small increase in GMP in some experiments. After allowing for leakage of nucleotides from the ROS, there was little light-induced conversion of ATP into ADP or AMP in the first 20 s after the bleaching light flash. The light-induced changes in nucleotide levels were unaffected by lowering the free Ca^{2+} activity to 1 μM or adding 1 mM of the cyclic nucleotide phosphodiesterase inhibitor, isobutylmethylxanthine, to the ROS suspension.

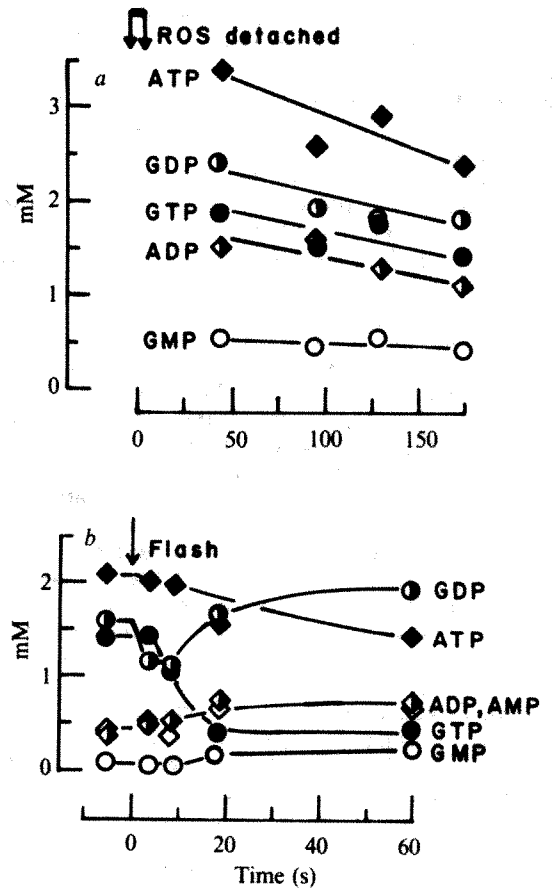

Fig. 2 Nucleoside phosphate levels in intact isolated frog ROSs: *a*, in darkness with time scale beginning the instant that separation from retinas began; *b*, after a 2-ms flash of green light that bleached 1% of the rhodopsin chromophores, time scale beginning at the flash. Light had little effect on ATP or ADP levels but produced a very fast disappearance of GDP followed by a conversion of GTP to GDP with a half time of about 10 s. The values have been corrected for the small slow loss of all nucleotides that occurs in the dark during the 5–10-min course of the experiments.

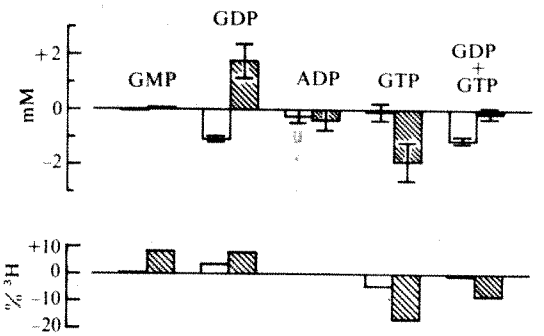

Fig. 3 Changes in guanine nucleotide levels in frog ROSs following a 2-ms 560-nm light flash that bleached 1% of the rhodopsin. Data from four experiments similar to that of Fig. 2*b*. Aliquots of ROS suspension were extracted after centrifugal filtration through silicone oil (see text) before (*a*), 4 s (*b*) and 64 s (*c*) after the bleaching flash. The observed nucleotide level in each aliquot was first corrected for leakage (Fig. 2*a*) by normalising all values to those that would have been obtained if the cytoplasmic ATP + ADP were exactly 5 mM. Open bars, change in nucleotides 4 s after flash. Hatched bars, change in nucleotides between 4 s and 64 s after light flash. Upper row, total extractable nucleotides. Mean of four experiments. Error bars, s.e.m.; lower row, ^{3}H-labelled nucleotides from ROS of two retinas incubated for 1 h in labelled guanosine in stirred, oxygenated glucose Ringer solution. At 4 s total extractable GDP dropped by 1 mM (process (3)), and both total and ^{3}H-labelled GTP dropped slightly between 4 s and 64 s. Total GTP was quantitatively replaced by GDP, while the decline in ^{3}H-labelled GTP was accompanied by the appearance of roughly equal amounts of GDP and GMP. There was no significant change in ATP in the 60 s following the flash.

Do all the guanine nucleotides occur in one light-sensitive pool? The experiments summarised in Fig. 3 suggest that they do not. The upper line of bars in the figure shows net changes in the total extractable guanine nucleotides in four experiments similar to that of Fig. 2*b*. In the first 4 s after the flash, the usual large drop in GDP was seen. Between 4 s and 64 s, GTP dropped and GDP rose by similar amounts. There was no significant change in the GMP level. The lower row of bars denotes changes in the acid-extractable tritiated nucleotides from ROSs of two retinas that had been incubated for 1 h in darkness in stirred, oxygenated glucose Ringer solution containing 20 μCi ml^{-1} of [8-^{3}H]guanosine (NEN). The specific activity of GTP recovered from the ROSs was about 1% of that of the guanosine. The GTP : GDP ratio for the labelled nucleotides was 3.8, whereas that for the total extractable GTP and GDP was 0.96. The ATP : ADP ratio was 7.6. Thus, the exchangeable guanine nucleotides had a phosphate potential much closer to that of the adenine nucleotides. This would be the case if about 74% of the extractable GDP in the ROS were bound to inexchangeable sites. The flash caused a small increase in [8-^{3}H]GDP at 4 s matched by an equal loss of tritiated GTP.

Control experiments on quick-frozen frog retinas showed that the labelled nucleotides were in the layer of outer segments and sedimented with intact ROSs. Thus, the guanine nucleotide pool of frog ROSs must consist of at least two parts: an exchangeable part comprising as much as 25% of the total, apparently following two parallel light-induced pathways:

$$\text{GTP} \rightarrow [\text{Cyclic GMP}] \rightarrow \text{GMP} \quad (1)$$

$$\text{GTP} \rightarrow \text{GDP} \quad (2)$$

and an inexchangeable part that shows process (2) and an additional reaction:

$$\text{GDP (acid soluble)} \rightarrow \text{GDP(acid inextractable)} \quad (3)$$

Process (1) is to be expected, as rod disks contain both guanyl cyclase[23-25] and cyclic nucleotide phosphodiesterase[26-29]. Because the main product of GTP metabolism in illuminated ROSs is GDP, not GMP, either process (2) is the main biochemical pathway for destruction of GTP, or GMP formed by process (1) must be rapidly phosphorylated to GDP.

Process (3) is a surprise. It is hard to reconcile with the protein inventory in the ROS. The binding sites are not likely to be on rhodopsin molecules because only one GDP is bound for every 2–2.5 rhodopsins and because in ROSs whose plasma membranes exclude DDC, at least 90% of the GDP will leak out on hydrodynamic shearing that renders the ROSs leaky to DDC. Thus, the binding sites must be able to leak out of the outer segments along with their bound GDP. The GDP binding resembles that shown by tubulin[30]. We have found tubulin in DDC-negative ROSs by SDS gel electrophoresis, but the abundance of tubulin monomers is less than 1 per 10 rhodopsin chromophores (W.E.R and W.A.H., unpublished). The light-induced binding reaction shows a large chemical gain: bleaching of 1 rhodopsin in 100 causes 1 GDP to become inextractable for every 2 photopigment chromophores in the ROS.

The light-induced conversion of GTP to GDP is much faster than that observed in isolated ROS disk membranes[20-22,31]. In intact ROSs at least 100 GTP molecules are converted to GDP for each photon absorbed by photopigment molecules during the 20 s following a flash, whereas less than 30 GTP molecules are split by ROS disks in a similar time for each photoisomerised rhodopsin chromophore[20,21]. As only 1 rhodopsin in 1,000 must be photoisomerised to activate the disk GTPase fully, the GTPase activity (if that is what process (2) represents) in the intact ROS must be more than 20 times that previously seen. It would be sufficient to drive a mechanism that removes 1,000 transmitter particles previously released in a photon response[15].

We thank Shuko Yoshikami and John George for discussions.

Potentiation of Ca^{2+}-dependent K^+ activation by theophylline is independent of cyclic nucleotide elevation

THE action potential in many nerve cells is followed by an after-hyperpolarisation (AH). In several types of neurone, this AH consists of two components: a brief voltage-sensitive K^+ conductance, and a longer Ca^{2+}-sensitive K^+ conductance (refs 1–5, see ref. 6 for review). In sympathetic neurones of the bullfrog, theophylline potentiates this Ca^{2+}-sensitive K^+ conductance[4]. As theophylline is a well known inhibitor of phosphodiesterase[7], the enzyme which catabolises cyclic nucleotides, we examined the role of cyclic nucleotide metabolism in the regulation of the spike AH. We used both electrophysiological and biochemical methods to investigate whether potentiation of the spike AH by theophylline is correlated with cyclic nucleotide elevation in bullfrog sympathetic neurones. Our results indicate that the potentiation of this Ca^{2+}-dependent K^+ conductance is apparently independent of cyclic AMP and cyclic GMP levels, and suggest that this potentiation by theophylline is not due to inhibition of phosphodiesterase.

The spike AH and other membrane potentials generated in sympathetic neurones were recorded by the sucrose gap technique, as reported previously[4]. Figure 1 shows the spike AH recorded following procedures which would be expected to increase cyclic nucleotide concentration. Theophylline (5 mM) increased the duration of the spike AH (Fig. 1*a*). Two other phosphodiesterase inhibitors, papaverine (0.1 mM)[8-10] and diazepam (0.1 mM)[11-13], however, had little effect on the duration of the spike AH (Fig. 1*b*, 1*c*). Stimulation of the cholinergic preganglionic nerve fibres which synaptically innervate the neurones in these sympathetic ganglia increases the content of both cyclic GMP and cyclic AMP[13,14]. However, neither the administration of the cholinergic agonist methacholine nor preganglionic stimulation prolonged the duration of the spike AH (Fig. 1*d*, 1*e*).

Figure 1*f* and *g* shows that the application of dibuturyl cyclic AMP (3 mM) or dibutyryl cyclic GMP (3 mM) also did not significantly alter the spike AH. As shown in Fig. 1*h*, theophylline (5 mM) increased the duration of the AH in the presence of papaverine (0.1 mM). This observation raised the question of whether the increase in AH duration by theophylline is due to inhibition of phosphodiesterase, as prior inhibition of this enzyme by papaverine might prevent any physiological action of theophylline that is mediated by phosphodiesterase inhibition. To evaluate this question, and to confirm that the experiments shown in Fig. 1 did alter cyclic nucleotide content, we measured both cyclic AMP and cyclic GMP concentrations by radioimmunoassay[15].

Figure 2 shows the change in cyclic AMP and cyclic GMP concentrations which were produced by the various experimental procedures shown in Fig. 1. The content of both cyclic AMP (Fig. 2*a*) and cyclic GMP (Fig. 2*b*) was elevated by the administration of methacholine and by each of the three phosphodiesterase inhibitors, theophylline, papaverine and diazepam. The interaction of papaverine and theophylline on cyclic nucleotide content is shown in Fig. 2*c* and *d*. If the potentiation of the spike AH induced by theophylline in the presence of papaverine results from further inhibition of phosphodiesterase, one would expect these two substances to have an additive effect on cyclic nucleotide levels. However, no additive effect was observed (Fig. 2*c*, *d*). In the presence of papaverine, theophylline reduced the concentrations of both cyclic AMP (Fig. 2*c*) and cyclic GMP (Fig. 2*d*) towards the control concentration seen before papaverine was added. Although the reason for this theophylline-induced decrease in cyclic nucleotide content is

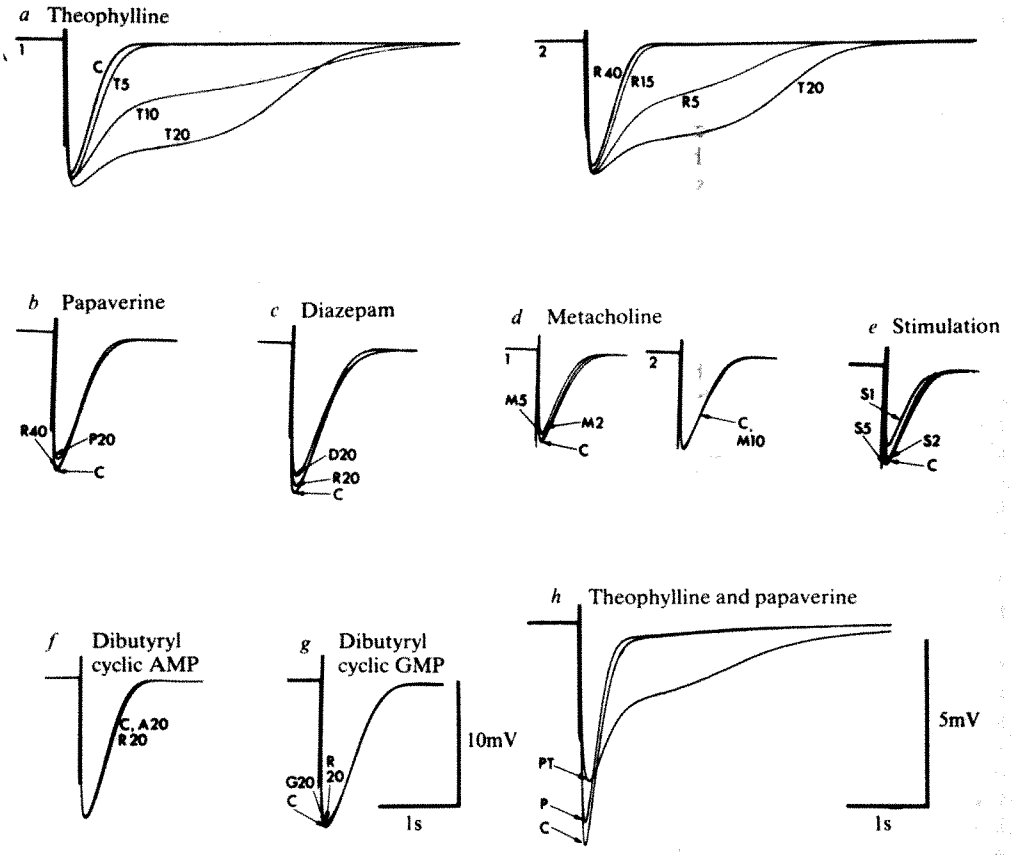

Fig. 1 Action potential after-hyperpolarisation (AH) recorded in conditions expected to increase cyclic nucleotide concentration. *a1*, Effect of theophylline on spike AH. Control AH before theophylline added (C), and superimposed records of spike AH after superfusion with Ringer's solution containing 5 mM theophylline for 5 min (T5), 10 min (T10) and 20 min (T20). Note prolongation of AH duration. *a2*, Recovery from theophylline effect. Spike AH after 20 min in 5 mM theophylline (T20), and superimposed recovery records of AH recorded 5 min (R5), 15 min (R15) and 40 min (R40) after beginning theophylline washout. *b*, Effect of papaverine on spike AH. Control spike AH before papaverine added (C), and superimposed records of AH after 20 min superfusion with 0.1 mM papaverine (P20), and recovery recorded 40 min after beginning papaverine washout (R40). *c*, Effect of diazepam on spike AH. Control AH before diazepam (C), and superimposed records of AH recorded after superfusion with 0.1 mM diazepam for 20 min (D20), and recovery recorded 20 min after beginning diazepam washout (R20). *d*, Effect of methacholine on spike AH; in the presence of 70 μM (−)tubocurarine. *1*, Control AH before methacholine (C), and superimposed records of AH recorded after superfusion with 1 mM methacholine for 1 min; records taken 2 min (M2) and 5 min (M5) after methacholine administration. *d2*, Control record (C) from same experiment as *d1* with superimposed record 10 min after administration of 1 mM methacholine for 1 min (M10). *e*, Effect of synaptic stimulation on spike AH. Control AH before stimulation (C), and superimposed records of AH recorded 1 min (S1), 2 min (S2) and 5 min (S5) after preganglionic stimulation. The sympathetic chain was stimulated between the eighth and ninth ganglia supramaximally with 1-ms pulses for 2 min at 10 Hz (see ref. 14). *f*, Effect of dibutyryl cyclic AMP on spike AH. Control AH before dibutyryl cyclic AMP (C), and superimposed records of AH recorded after superfusion with 3 mM dibutyryl cyclic AMP for 20 min (A20) and recovery record 20 min after beginning dibutyryl cyclic AMP washout (R20). *g*, Effect of dibutyryl cyclic GMP on spike AH. Control AH before dibutyryl cyclic GMP (C), and superimposed records of AH recorded after superfusion with 3 mM dibutyryl cyclic GMP for 20 min (G20) and recovery record 20 min after beginning dibutyryl cyclic GMP washout (R20). *h*, Effect of theophylline on spike AH in the presence of papaverine. Control AH before addition of either drug (C), and superimposed record of AH recorded after superfusion with 0.1 mM papaverine (P). The third superimposed trace was recorded 20 min after the addition of 5 mM theophylline to the Ringer's solution containing papaverine (PT). Note the increased duration of the spike AH after the addition of theophylline. The experiments were carried out on the ninth or tenth paravertebral sympathetic ganglion of the bullfrog by the sucrose gap method. Action potentials were elicited by antidromic stimulation once per minute, as reported previously[4]. The depolarising phase of the action potential was obscured by the stimulus artefact. The spikes were truncated for the purpose of illustration. All records illustrated were obtained using a Brush 280 pen recorder. The composition of the Ringer's solution was (mM): NaCl 100; KCl 2; CaCl 1.8; Tris-HCl 16 (*p*H 7.2); glucose 1 g l^{-1}.

not clear, it may have important implications for our understanding of cyclic nucleotide metabolism.

Our data show that although theophylline, papaverine, diazepam, methacholine and preganglionic stimulation increase the concentrations of both cyclic AMP and cyclic GMP, only theophylline prolongs the duration of the spike AH. This indicates that the duration of the spike AH does not seem to be associated with the elevation of cyclic AMP and cyclic GMP. Consistent with this is the observation that the administration of dibutyryl cyclic AMP or dibutyryl cyclic GMP did not significantly affect the spike AH. The observation that theophylline reduced cyclic nucleotide content in the presence of papaverine but potentiated the spike AH, indicates that the potentiation of this Ca^{2+}-dependent K^+ conductance is independent of cyclic nucleotide elevation. This observation also suggests that the potentiation of the AH by theophylline is not due to phosphodiesterase inhibition. This interpretation has additional significance in view of the fact that the potentiation of various responses in neurones by theophylline has often been cited as evidence for cyclic nucleotide mediation of such phenomena[16–18].

In the sympathetic neurones studied here, potentiation of the spike AH by theophylline is dependent on the presence of extracellular Ca^{2+} ions[4]. During an action potential, in addition to an influx of Na^+ ions there is an influx of Ca^{2+} ions into these neurones[19]. It is likely that this Ca^{2+} influx activates the K^+ conductance which prolongs the duration of the spike AH. Busis and F.F.W.[4] suggested that theophylline may potentiate the spike AH by increasing the stimulus-induced entry of Ca^{2+} ions. Recently, Klein and Kandel[20] reported that phosphodiesterase inhibitors prolong the duration of a Ca^{2+} spike in a sensory neurone of *Aplysia*. They showed that the prolongation of this Ca^{2+} conductance could also be produced by synaptic stimulation and suggested that cyclic AMP was mediating this effect of the neurotransmitter, serotonin. Cyclic nucleotides have also been reported to prolong a Ca^{2+}-dependent K^+ activation in spinal motoneurones[21]. Our data, on the other hand, indicate that the prolongation of the Ca^{2+}-dependent K^+ activation in sympathetic neurones is independent of cyclic nucleotide elevation. It thus seems that various mechanisms may be regulating Ca^{2+}-dependent conductance changes in different types of neurone. Such a diversity is further illustrated by the recent observation that Ca^{2+}-dependent conductance changes can be reduced rather than enhanced by neurotransmitter action[22,23].

The AH following an action potential produces the absolute and relative refractory periods which prevent spike reactivation after short time intervals and thus limit spike firing frequency. An understanding of the cellular mechanisms controlling the

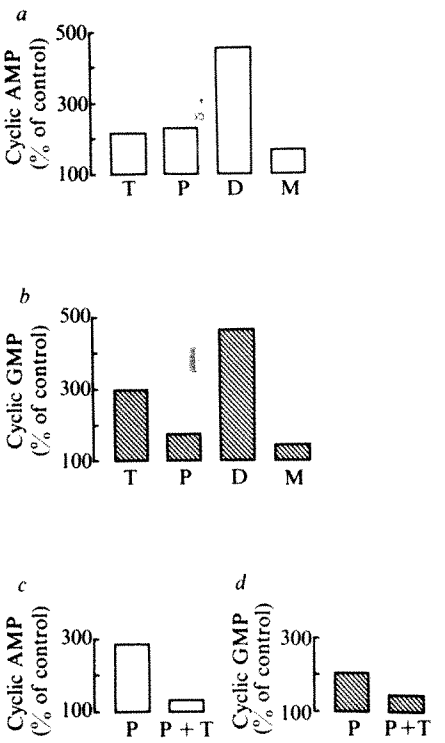

Fig. 2 Effect of phosphodiesterase inhibitors and methacholine on cyclic nucleotide concentration in bullfrog sympathetic ganglia. *a*, Increase in cyclic AMP content produced by theophylline (T), papaverine (P), diazepam (D) and methacholine (M) illustrated as per cent of control. For each experiment, $n = 5$ or more. The changes in cyclic AMP concentrations were as follows, expressed as pmol per mg protein (mean ± s.e.m.). Incubation of ganglia with 5 mM theophylline for 20 min increased cyclic AMP concentration from 10.53 ± 1.63 to 23.26 ± 2.42 ($P < 0.005$). Incubation with 0.1 mM papaverine for 20 min increased cyclic AMP from 17.83 ± 1.61 to 41.9 ± 1.37 ($P < 0.001$). Incubation with 0.1 mM diazepam for 20 min increased cyclic AMP from 20.5 ± 2.9 to 93.17 ± 32.3 ($P < 0.05$). Incubation with 1 mM methacholine for 2 min increased cyclic AMP from 40.05 ± 6.69 to 70.08 ± 12.21 ($P < 0.1$) determined 5 min after M administration, in the presence of 70 μM (−)tubocurarine. *b*, Increase in cyclic GMP content produced by theophylline, papaverine, diazepam and methacholine illustrated as per cent of control. For each experiment, $n = 5$ or more. The changes in cyclic GMP concentrations were as follows, expressed as pmol per mg protein (mean ± s.e.m.). Incubation of ganglia with 5 mM theophylline for 20 min increased cyclic GMP concentration from 0.97 ± 0.12 to 2.92 ± 0.4 ($P < 0.001$). Incubation with 0.1 mM papaverine for 20 min increased cyclic GMP from 0.98 ± 0.07 to 1.78 ± 0.18 ($P < 0.005$). Incubation with 0.1 mM diazepam for 20 min increased cyclic GMP from 0.29 ± 0.03 to 1.38 ± 0.29 ($P < 0.005$). Incubation with 1 mM methacholine for 2 min increased cyclic GMP from 0.58 ± 0.13 to 0.84 ± 0.12 ($P < 0.4$) determined 5 min after M administration, in the presence of 70 μM (−)tubocurarine. *c*, Effect of theophylline on the % increase in cyclic AMP produced by papaverine. For each experiment, $n = 5$ or more. Incubation of ganglia with 0.1 mM papaverine for 40 min increased cyclic AMP concentration from 17.83 ± 1.61 to 51.5 ± 6.51 ($P < 0.001$). However, when ganglia were incubated with 0.1 mM papaverine for 20 min followed by 0.1 mM papaverine plus 5 mM theophylline for 20 min, cyclic AMP increased to only 24.3 ± 1.9 ($P < 0.05$). *d*, Effect of theophylline on the % increase in cyclic GMP produced by papaverine. For each experiment, $n = 5$ or more. Incubation of ganglia with 0.1 mM papaverine increased cyclic GMP concentration from 0.98 ± 0.07 to 2.02 ± 0.17 ($P < 0.001$). However, when ganglia were incubated with 0.1 mM papaverine for 20 min followed by 0.1 mM papaverine plus 5 mM theophylline for 20 min, cyclic GMP increased to only 1.5 ± 0.19 ($P < 0.05$). Cyclic nucleotide content was determined as follows. After dissection, ganglia were equilibrated in oxygenated Ringer's solution for 1–2 h. After test procedures, ganglia were plunged into liquid nitrogen. Samples were fixed in 0.5 ml 0.1 M HCl in 90% methanol at −20 °C for 2 h. Following addition of 1 ml water, samples were extracted at 80 °C for 30 min and centrifuged. The supernatants were transferred, lyophilised, resuspended in water and assayed by radioimmunoassay using the method of Harper and Brooker[15]. Protein content was determined by the method of Lowry[24].

duration of the spike AH is thus important for determining the factors involved in regulating excitability and the frequency of spike firing. Further investigation of the potentiation of the spike AH by theophylline may lead to a greater understanding of the molecular mechanisms involved in the control of Ca^{2+}-sensitive K^+ conductances.

We thank Drs G. Brooker and W. Terasaki for gifts of antibody to cyclic AMP, Dr F. Murad for antibody to cyclic GMP, Dr W. E. Scott of Hoffman LaRoche for diazepam, Dr N. A. Busis for review of the manuscript, and Ms Charlene A. French for typing the manuscript.

Whitefly have the highest contraction frequencies yet recorded in non-fibrillar flight muscles

ASYNCHRONOUS (myogenic) insect flight muscles have evolved independently at least seven times[1]. Although such muscles do not necessarily contract at particularly high frequencies, potentially they allow far greater wing stroke rates than synchronous muscle which, because of the delays involved in muscle activation, has been believed to be incapable of operating at frequencies above ~100 Hz (ref. 2), unless power output is small and much of the muscle volume occupied by sarcoplasmic reticulum[3]. Asynchronous muscle has so far always been shown to be of the 'fibrillar' histological type, and this correspondence has been assumed to be invariable[1]. Predictably, very small insects, for which a high stroke frequency is believed to be essential[2], almost always have fibrillar flight muscle. However, a few groups, notably the hemipterous family Aleyrodidae (whitefly), have muscle of the 'close-packed' type, hitherto supposed to operate only synchronously[1]. We have measured cinematographically the wing-beat frequencies of the whitefly *Trialeurodes vaporariorum* (Westwood), and report here that they are well above the usually assumed limit for synchronous functioning. Either this limit, or the assumption that all asynchronous muscle is of fibrillar type, must therefore be incorrect.

The studies of Greenwalt[4] indicate that, albeit with many deviations, insect wing-beat frequencies vary approximately as the reciprocal of the wings' linear dimensions. Weis-Fogh has confirmed that within many families and superfamilies this is

0028–0836/79/310402—02$01.00
© Macmillan Journals Ltd 1979

almost exactly true, and has discussed the mechanical and aerodynamic reasons for it[5].

The smallest flying insects which lack fibrillar muscle are probably some Nepticulidae (Lepidoptera), with wing length 2 mm or less, and Aleyrodidae (Hemiptera), whose wings are often shorter than 1.5 mm, and of which *Trialeurodes vaporariorum* undoubtedly has close-packed flight muscle[1]. Insects of this size might be expected to have wing-beat frequencies well above the assumed limit of 100 Hz for synchronous flight muscle. Various small Diptera with wings between 2 and 7 mm long show frequencies between 150 and 600 Hz (ref. 4), and psyllid, mirid and cimicid Hemiptera within the same size range have been timed at between 100 and 150 Hz (ref. 1). All these have fibrillar flight muscle. We have filmed *T. vaporariorum* in free flight, using a Hycam high-speed cine camera (Hadland), operating at approximately 3,000 frames per s. The exact framing rate was measured using a timing light generator operating a neon timing light within the camera which marked the film at precisely 1,000 Hz.

The flapping frequencies of nine individuals were measured during short flights. They varied between 143 and 181 Hz, that is between 40% and 80% higher than the previously supposed maximum contraction frequency for synchronous flight muscle.

The highest wing-beat frequencies previously recorded for insects using close-packed muscle are 90–95 Hz in some sphingid moths[2]. *Trialeurodes*, by contrast, falls in the same frequency range as many medium-to-large Diptera and Hymenoptera[4] and rather above those of most recorded Coleoptera[4] and Heteroptera[1]. Published figures for Aphididae, which like Aleyrodidae are Homoptera but which have fibrillar muscle, all fall below 100 Hz (ref. 1). Why asynchrony should have evolved in aphids but not in the usually smaller and more rapidly beating whitefly is unclear.

For insects of their size the wing-beat frequency of *Trialeurodes* is still strikingly low. Two factors may contribute to this. First, Pringle (ref. 2, text and subsequent discussion) has suggested that Aleyrodidae may be able to limit their frequency through their unusually low wing loading, which would reduce the minimum power necessary for flight. Second, Weis-Fogh[5] explains the relatively low frequency of *Drosophila*—195–240 Hz in *Drosophila virilis*[6]—by their use of the 'clap and fling' mechanism[7] for generating extra lift. *Trialeurodes* performs a dorsal clap and fling in each wing beat; also the wing loading, which we have calculated by dividing the mean weight of 800 individuals by the mean wing area of a sample of 15, is exceptionally low. Its value, 0.047 kg m^{-2}, may be compared with 0.35 kg m^{-2} for the larger *D. virilis*[6] and 0.086 kg m^{-2} for the smaller *Encarsia formosa* (recalculated from Weis-Fogh[7] using Ellington's figure for wing area[8]). Such a low wing loading will undoubtedly have contributed to a low power requirement, which may be a prerequisite for high-frequency synchronous muscle—if this is what *Trialeurodes* is using.

Contraction frequencies up to 180 Hz in close-packed flight muscle imply one of two possibilities. First, the previously assumed upper frequency limit for synchronous flight muscle contraction may be far too low. Alternatively, the asynchronous mechanism may not, after all, be restricted to fibrillar muscle. This certainly cannot be ruled out; many different kinds of muscle are now known to display the delayed stretch activation which is required for asynchronous operation. The crucial information now required is the stimulation frequency of the muscles. Without this it is impracticable to judge which explanation is correct.

We thank Professor J. W. S. Pringle and Dr M. J. Cullen for their comments.

Antiserum specific for motor nerve terminals in skeletal muscle

OUR understanding of synaptic function and development has benefited from the availability of neurotoxins that bind specifically to acetylcholine receptors and acetylcholine esterase at the neuromuscular junction[1–4]. It would be of additional value to have molecular probes for other components of this accessible and well-studied synapse, such as the nerve terminal. Antibodies to the synaptic vesicles that are concentrated in the motor nerve terminal would constitute one such marker; unfortunately, these vesicles are present in such small amounts that their purification has not yet been achieved. It is, however, possible to purify cholinergic synaptic vesicles from the electric organ of the elasmobranchs, *Narcine brasiliensis*[5] and *Torpedo marmorata*[6], and to obtain antisera to them (S.S.C. and R.B.K., in preparation). We report here that antibodies in anti-*Narcine* vesicle sera bind specifically to motor nerve terminals in skeletal muscle.

We have used the technique of indirect immunofluorescence to detect binding of antibodies to nerve terminals. Unfixed tissue (rat diaphragm except where noted) was frozen in liquid N_2 and sectioned in a cryostat. Sections were incubated with rabbit antiserum and then with a mixture of fluorescein-conjugated second antibody (goat anti-rabbit IgG) and rhodamine-conjugated α-bungarotoxin[3,7]. Appropriate filter combinations enabled us to excite and view fluorescein or rhodamine selectively, and thus to compare the distribution of immunohistochemical stain with that of α-bungarotoxin, which binds tightly and specifically to the acetylcholine receptors that are clustered in the postsynaptic membrane of the neuromuscular junction[1,2].

Our main results are shown in Fig. 1. Unfractionated antisera to whole *Narcine* synaptic vesicles[5] stained a variety of membranes in rat skeletal muscle, including those of blood vessels, nerves and muscle fibres (Fig. 1*a*). Most intensely stained, however, were small patches in the muscle fibres' surface (Fig. 1*a*), which could be identified as neuromuscular junctions because they also stained with rhodamine-α-bungarotoxin (Fig. 1*b*). Adsorption of antiserum with vesicle-free membranes from *Narcine* electric organ (S.S.C. and R.B.K., in preparation) removed antibodies that stained nonsynaptic membranes, but spared antibodies that stained the neuromuscular junction (Fig. 1*c* and *d*). This adsorbed antiserum also stained neuromuscular junctions in frog and chick skeletal muscle, and the innervated face of *Narcine* electroplaques. Adsorption of serum with sonicated *Narcine* vesicles reduced staining markedly. Preimmune serum did not stain neuromuscular junctions detectably. Thus, antibodies in anti-vesicle serum cross-react with components of mammalian, amphibian and avian neuromuscular junctions.

Two observations indicate that the neuromuscular components to which the antibodies bound were associated with nerve terminals. First, antibodies stained structures that resembled nerve terminals in size, shape and position[8,9]: comparison of the distribution of fluorescein-antibody and rhodamine-toxin showed that antibodies stained 1–3 μm wide structures (Fig. 1*c*, inset) that were tangential to toxin-stained gutters of postsynaptic membrane (Fig. 1*d*, inset). Second, antibodies did not

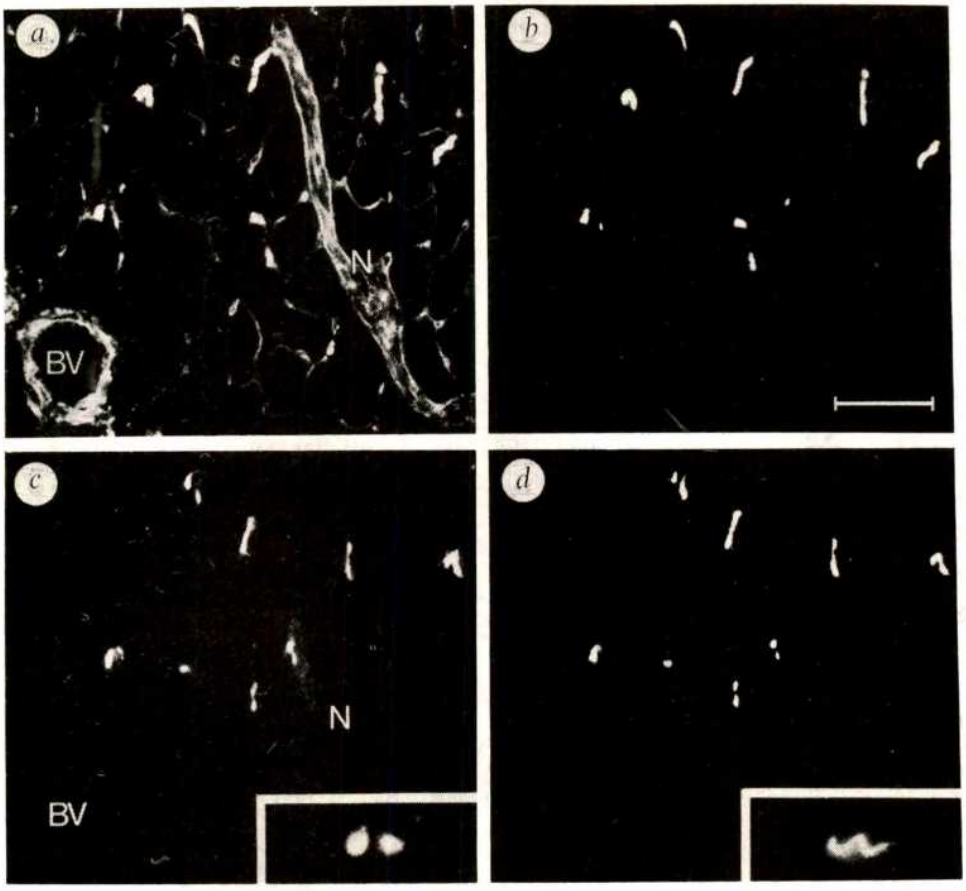

Fig. 1 *a*, *b*, Cross-section (4 μm) of frozen, unfixed rat diaphragm were incubated for 30 min at room temperature with rabbit antiserum to *Narcine* synaptic vesicles (1:60 dilution in phosphate-buffered saline containing 1% BSA). They were then washed and stained for 30 min at room temperature with a mixture of fluorescein-'second antibody' (fluorescein-goat anti-rabbit IgG; Cappel Laboratories; 1:50 dilution) and rhodamine-α-bungarotoxin (10 nM; a gift of P. Ravdin and D. Berg, University of California, San Diego). The section was photographed with filters appropriate to show either fluorescein (*a*) or rhodamine (*b*). (Immunohistochemical methods are detailed elsewhere[11]). Fluorescein fluorescence reveals distribution of anti-vesicle antibodies and rhodamine the distribution of acetylcholine receptors[3,7] and thus location of neuromuscular junctions. The coincidence of fluorescein and rhodamine shows that antibodies stain the neuromuscular junction; blood vessels (BV), nerves (N), and the muscle fibres' surface also stain. *c*, *d*, Section adjacent to that shown in *a* and *b*, incubated with anti-vesicle serum (1:60 dilution) that had been adsorbed with non-synaptic membrane from *Narcine* (5 μg membrane protein/μl antiserum, 16 h, 4 °C), and then stained with fluorescein-second antibody and rhodamine-α-bungarotoxin: *c*, fluorescein; *d*, rhodamine. Neuromuscular junctions stain, but extrasynaptic portions of the muscle fibre surface do not. Blood vessel and nerve were stained too faintly to be visible in the micrograph, but their positions are marked. Insets to *c* and *d* show a single neuromuscular junction (from the section in *c* and *d*), photographed to show fluorescein (inset to *c*) or rhodamine (inset to *d*). Antibody stains nerve terminals that abut the toxin-stained postsynaptic membrane. The scale bar in *b* is 50 μm and applies to *a*–*d*; 10 μm for insets.

stain endplates in muscles that were denervated 1 week before they were frozen and sectioned. At this time, postsynaptic receptors and Schwann cells remain, but nerve terminals have disappeared[10]. There is, therefore, little doubt that antibodies bind to antigens in the motor nerve terminal or on its surface.

The antigens detected by the anti-vesicle serum are distributed non-uniformly in the motoneurone, as would be expected if they were associated with synaptic vesicles. Although nerve terminals stained intensely, axons in the nerve or in intramuscular nerve branches, cut either longitudinally or in cross-section, did not stain well (Fig. 1*c*), nor did the cytoplasm of motoneurone somata or proximal dendrites, seen in frozen sections of rat spinal cord. (The synapse-rich gray matter of the spinal cord did stain, however, raising the possibility that nerve terminals other than motor nerve terminals contain antigen; experiments to examine this possibility are in progress.)

In conclusion, antibodies directed against *Narcine* synaptic vesicles recognise motor nerve terminals in mammalian, amphibian and avian skeletal muscle, and distinguish terminal from preterminal portions of motor axons. These antibodies should facilitate studies of the function, development, and molecular composition of nerve terminals at the neuromuscular junction.

T-cell-derived helper factor allows Lyt 123 thymocytes to differentiate into cytotoxic T lymphocytes

IT is generally accepted that the diversity of T-cell responsiveness is generated in the thymus[1]. It is also known that except for a few Lyt 1 cells all thymocytes express the Lyt 123 phenotype[2,3]. Surprisingly, thymocytes are poorly responsive *in vitro*[4], and only the medullary thymocytes, comprising 5–10% of the total thymic cell population, show an *in vitro* responsiveness comparable with that of peripheral T cells[5]. Cortical thymocytes, comprising 90–95% of all thymocytes, have previously been considered to be immature and immunologically incompetent[4]. The result reported here show that thymocytes are able to generate alloantigen-, virus- and hapten-specific cytotoxic T lymphocytes (CTL), provided a T-cell-derived helper factor is added to the cultures. Furthermore, through the use of cell separation techniques we conclude that in the presence of the helper factor the great majority of Lyt 123^+ thymocytes have the capacity to differentiate into either alloreactive or H-2-restricted CTL.

The tissue culture system for the induction of alloreactive, trinitrophenyl (TNP)-specific and Sendai virus-specific CTL as well as the preparation of TNP-conjugated or Sendai virus-infected targets has been described elsewhere[6–8]. The target cells used in the 3-h ^{51}Cr-assay were *in vitro* propagated P815 ($H\text{-}2^d$) mastocytoma cells, LS cells ($H\text{-}2^k$) (Flow) and EL4 ($H\text{-}2^b$) tumour cells. Peanut agglutinin (PNA)-receptor-positive cells were detected using fluorescein isothiocyanate (FITC) labelled PNA (Industrie Biologique Française)[9,10]. The preparation of semi-purified T-cell-derived helper factor has been described in detail elsewhere[11]. Briefly, CBA mouse-derived splenic T cells were cultured in serum-free medium for 24 h in the presence of 1 $\mu g\,ml^{-1}$ concanavalin A (Pharmacia). The culture supernatant was concentrated 20-fold, eluted from a Sephadex G-100 column and the fractions with 'secondary CTL-inducing activity'[11] were pooled and concentrated 20-fold.

As can be seen in Table 1, CBA mouse ($H\text{-}2^k$)-derived splenic responder T cells are able to mount *in vitro* an efficient CTL response towards $H\text{-}2^d$ alloantigens. Similarly efficient H-2-restricted CTL responses can be generated which are specific for TNP-conjugated or Sendai virus-coated syngeneic targets. In contrast, CBA mouse-derived thymocytes used as responder cells responded only poorly, if at all. However, the low responsiveness of thymocytes was converted to high responsiveness when an optimal concentration of T-cell-derived helper factor was added to the cultures (Table 1). The augmented CTL responsiveness of thymocytes was observed for the induction of both alloreactive CTL and H-2-restricted TNP- or Sendai virus-specific CTL.

These results support two broad conclusions. First, thymocytes are immunocompetent at the level of alloreactive and H-2-restricted CTL precursors. Second, a rate-limiting step during the *in vitro* induction of thymocyte-derived CTL can be bypassed by supplementing the cultures with T-cell-derived helper factor.

Thymocytes can be separated into two classes of cells. Medullary thymocytes, comprising 5–10% of thymocytes, are immunocompetent, have high H-2 and low Thy-1 density[4] and are PNA-receptor negative[10] and cortisone resistant[5]. In contrast, cortical thymocytes, which represent 90–95% of thymocytes, are PNA-receptor positive[9,10], have low H-2 and high Thy-1 density[4] and are believed to be immunologically incompetent[4]. In view of the observed ability of thymocytes to generate CTL in the presence of T-cell-derived helper factor, we tested whether the use of cell separation techniques would allow us to define a particular subpopulation which responded in the culture conditions used.

CBA mouse-derived thymocytes were subject to 1*g* velocity sedimentation using the Bont–De Koningh separation apparatus[12]. Viable cells of the individual fractions obtained were tested for PNA-positive cells and for their CTL responsiveness to $H\text{-}2^d$ stimulator cells, TNP-conjugated syngeneic stimulator cells and Sendai virus-coated syngeneic cells.

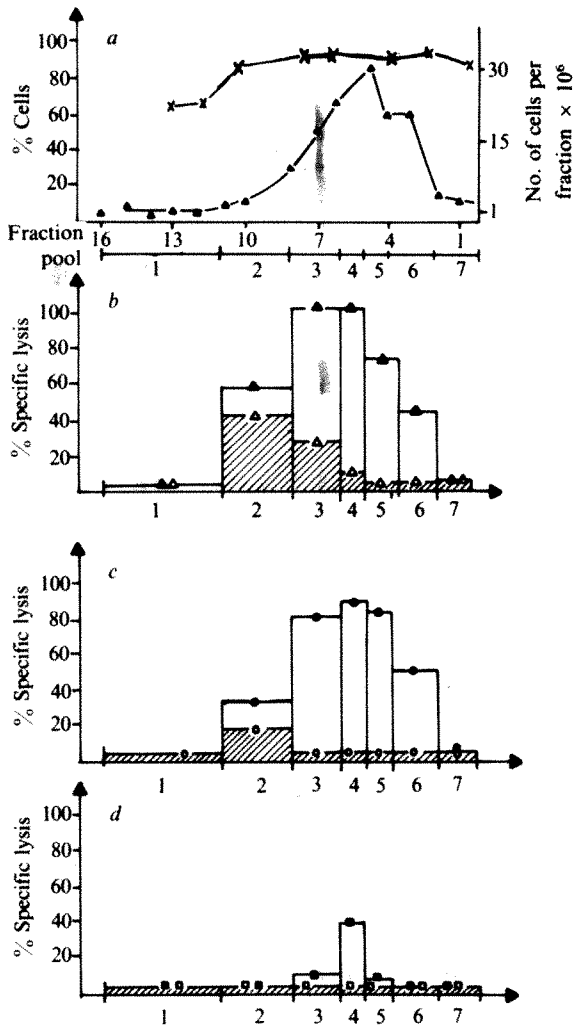

Fig. 1 CTL responsiveness pattern of thymocytes fractionated according to cell size. *a*, CBA mouse-derived thymocytes (2×10^8) were subjected to 1*g* velocity sedimentation using the Bont–De Koningh apparatus[12]. One of the advantages of this apparatus is the short sedimentation time required to separate the cells to be fractionated. This is achieved by turning the sedimentation vessel from its vertical position into the horizontal position. The number of viable cells per individual fraction obtained is given. Note that fraction 1 contains the very small cells whereas fraction 15 contains the very large cells. × Indicates the % of cells binding FITC-conjugated PNA. *b*, Fractionated thymocytes (3×10^6) were cultured with 1×10^6 irradiated (1,000 rad) BALB/c stimulator cells in TC-24 Linbro culture plates in the absence (△) or presence (▲) of 50 μl of semi-purified[11] T-cell-derived helper factor. After 5 d the lytic activity generated was tested in a 3-h ^{51}Cr-assay against P815 target cells at a ratio of attacker to target cells of 20:1. Background lysis of P815 targets was 9%. *c*, Fractionated thymocytes (3×10^6) were cultured with TNP-conjugated CBA spleens in the absence (○) or presence (●) of 50 μl semi-purified T-helper factor. After 5 d the lytic activity generated was assayed against TNP-conjugated LS cells at a ratio of CTL to target of 20:1. Background lysis was 12%. *d*, Fractionated CBA thymocytes (3×10^6) were cultured with 1×10^6 Sendai virus-coated syngeneic spleen cells in the absence (□) or presence (■) of 50 μl T-cell-derived helper factor. After 5 d the lytic activity generated was tested against Sendai virus-coated LS target cells at a ratio of CTL to target of 20:1. Background lysis was 17%. A similar responsiveness pattern was noted with fractionated BALB/c ($H\text{-}2^d$) and C57 BL/6 ($H\text{-}2^b$) thymocytes, the only variable being that in the absence of T-helper factor no response was obtained.

Figure 1 shows the results of a representative experiment. As can be seen from the cell distribution profile, thymocytes could be separated on the basis of cell size. PNA-negative cells were found only in the medium-to-large sized cell fractions. Cells collected in fractions 1–8 were PNA positive. With regard to

CBA mouse-derived responder cells (4×10^6) were cultured in the presence of the respective X-irradiated (1,000 rad) splenic stimulator cells (1×10^6) in 2 ml of medium in Linbro FB-24 Tc multidish culture trays (Linbro). Cultures contained 5% fetal calf serum, 10 mM HEPES, 2×10^{-5} M 2-mercaptoethanol with or without T-cell-derived helper factor[11]. After 5 d incubation at 37 °C, the cells were collected and set up in a standard 3-h ^{51}Cr-release assay against the target cells listed. The preparation of target cells using 10 mM 2,4,6-trinotribenzene sulphonic acid (Sigma) of β-propiolactone-inactivated Sendai virus suspension (Lot no. 138-1, Connaught) has been described elsewhere[8]. Background lysis of the target cells did not exceed 17%; % specific lysis represents the mean of triplicate determinations. In no case did the standard deviation exceed 5%.

cytolytic activity, medium-to-large sized thymocytes were able to mount CTL responses when stimulated *in vitro* with allogeneic stimulator cells, but were less responsive when stimulated with TNP-conjugated cells, and were unresponsive to stimulation with Sendai virus-coated syngeneic cells (Fig. 1). The unexpected finding, however, was that the apparent immunoincompetence of the large cell pool of medium-to-small sized thymocytes was converted to a state of high responsiveness when the T-cell-derived helper factor was added to the cultures. Interestingly, in the presence of this factor medium-to-small sized thymocytes not only mount efficient CTL responses towards alloantigens, but are also able to generate H-2-restricted CTL responses for the hapten TNP. Even Sendai virus-specific CTL could be induced from thymocytes of pool 4. The data in Fig. 1 also show that the very large and very small thymocytes were unable to generate CTL. In this context it is noteworthy that medium-to-small thymocytes were all PNA positive. This marker has recently been attributed to cortical thymocytes[10], known to express the Lyt 123 phenotype[3]. We therefore conclude that in the conditions described cortical thymocytes can differentiate into alloreactive as well as H-2-restricted CTL.

The experiments described formally demonstrate that depending on the 'antigen' used, thymic Lyt 123 T cells have the potential to give rise to H-2-restricted TNP or virus-specific CTL, or to non-restricted alloreactive CTL. The results also suggest that within cortical thymocytes both alloreactive and H-2-restricted CTL precursors express the Lyt 123 phenotype, and that at least at the level of CTL precursor cells, cortical thymocytes already express an antigen receptor diversity comparable with that of peripheral T cells. Obviously, at the level of CTL precursors cortical thymocytes are immunocompetent, and have the potential to respond efficiently to either alloantigens or foreign antigens. Thus, if the cortex of the thymus represents the site for the generation of the T-cell repertoire, immunocompetent cortical thymocytes are the result of these events. It should be stressed that *in vitro* the expression of the immunocompetence of cortical thymocytes occurs only in the presence of a helper factor previously shown to be derived from activated Lyt 1 T cells[11]. In fact, *in vitro* the rate-limiting step for the differentiation of Lyr 123 thymocytes into CTL represents the presence of the T-cell derived helper factor (Fig. 1).

Although the mechanism of this T–T-cell interaction is unknown, our experiments raise the question as to why within peripheral T cells of adult mice alloreactive T cells develop from the Lyt 23 T-cell subset[2]. Because, within the thymus, Lyt 123 T cells apparently represent the precursor pool of alloreactive CTL, a shift from Lyt 123 to the Lyt 23 T cell must take place. Recently, Burakoff *et al.*[13] provided convincing evidence that in mice within 3 weeks of birth the phenotype of peripheral alloreactive CTL precursors changes from Lyt 123 to Lyt 23. As the Lyt 23 phenotype is characteristic of H-2-restricted CTL, alloreactive CTL and memory T cells (refs 14–16 and unpublished results), and as H-2-restricted CTL specific for 'foreign antigens' to cross-react with alloantigen[17–19], we postulate that alloreactive peripheral Lyt 23 CTL precursors represent memory cells of virus-specific H-2-restricted CTL which by chance cross-react with alloantigen. A prediction of this view is that H-2-restricted versus non-restricted cytolysis is not a function of CTL, but a result of the respective target antigen recognised. In accordance with this we recently defined an *in vitro* propagated monoclonal CTL line ($H\text{-}2^k$) specific for allogeneic K^d targets. These monoclonal CTL also lyse (unpublished results) Sendai virus-infected syngeneic cells in an H-2-restricted manner.

Lymphomas with cytotoxic activity

TUMOURS of antibody-secreting B lymphocytes (myeloma tumours) have contributed greatly to our understanding of antibody structure and function. T-lymphocyte tumours that retain effector activities might, if they exist, prove to be similarly useful for analysing T cells and their key components. The recent finding that a T lymphoma is capable of crawling on other cells, like antigen-activated normal T lymphocytes[1], prompted

Per cent specific target cell lysis is defined as 100(ER − SR)/(100 − SR), where ER (experimental release) and SR (spontaneous release) are percentages of ^{51}Cr release from target cells in, respectively, the presence and absence of Con A. Values are mean ± s.d. of determinations at lymphoma to target cell ratios of 13 and 25. The presence of lymphoma cells slightly (1 or 2%) decreased the spontaneous release of ^{51}Cr from target cells (in the absence of Con A). The target cells, MOPC-167 cells (H-2^d), were labelled by incubation in medium containing $Na_2{}^{51}CrO_4$, and cytotoxicity was assayed as described[13]. Cytotoxic cells used as positive controls for the Con A-dependent cytolysis were peritoneal exudate cells taken from BALB/c (H-2^d) mice that had had two intraperitoneal injections of EL-4 (H-2^b) cells[1], that is, H-2^d anti-H-2^b. TB-1 and TB-3 arose as spontaneous lymph node lymphomas in old (>14 month) thymectomised AKR mice; TB-2 arose as a spontaneous spleen lymphoma in a 14–16-month-old AKR mouse with an atrophic thymus[3]. These three lymphomas were adapted to grow in culture by Durda, Boos and Gottlieb[27]. Ib and UM-2, and CAM-1 are maintained in C58 and BALB/c mice, respectively, by intraperitoneal passage of cells from enlarged spleens. The seven DBA/2 tumours are maintained in ascites tumours in DBA/2 or CD2 F_1 mice. All other lymphomas are maintained in culture.

* Source from which the lymphoma was derived, not necessarily the tissue in which neoplastic transformation took place. LN = lymph node; Spl = spleen.

† Spont. = spontaneous; MuLV = murine leukaemia virus; DMBA = dimethyl benzanthracene; MCA = methylcholanthrene.

‡ UM-1 and UM-2 were isolated by L. Pease and W. H. Murphy, CAM-1 by T. W. Chang, E. Celis and H. N. Eisen, F39 and PF6-MELN by P. Fahnestock, N. H. Hopkins and P. D. Gottlieb, and AKR-3T by N. Rosenberg.

us to investigate whether some lymphocytic tumour cells can, like normal cytotoxic T lymphocytes, lyse target cells. We report here that they can.

Because it was unlikely that any particular cytotoxic T lymphoma would be specific for any of the few target cells available to us, we included concanavalin A (Con A) in the assay mixture of lymphoma cells and target cells. In the presence of Con A cytotoxic T cells lyse target cells nonspecifically, evidently because Con A links killer and target cells and activates the killer cell's lethal mechanism[2]. Initially we used cells of a myeloma (MOPC-167) of BALB/c mice as targets.

In a typical assay, 1×10^4 ^{51}Cr-labelled MOPC-167 cells and 0 to 50×10^4 lymphoma cells were mixed in a total volume of 200 μl of a standard cell culture medium (RPMI-1640 with 10% fetal calf serum), with or without Con A (5 μg ml^{-1}). The cells were incubated at 37 °C for 4 h, and the ^{51}Cr released into the medium by the target cells was measured. A positive control was included in each assay: either peritoneal exudate lymphocytes from BALB/c mice that had been immunised against allogeneic EL-4 lymphoma cells of C57Bl/6 mice[1], or one of the lymphomas with cytotoxic ('killer cell') activity (see below).

None of the 24 lymphomas tested was cytotoxic in the absence of Con A, but three (TB-1, TB-2 and TB-3) had cytotoxic activity in the presence of Con A (Table 1). Representative titrations are shown in Fig. 1. The three active lymphomas also caused Con A-dependent lysis of other target cells (P815, a mastocytoma of the DBA/2 strain, and EL-4), and their cytotoxic activity was facilitated just as well by phytohaemagglutinin as by Con A (data not shown).

The surface antigens of TB-1, TB-2 and TB-3 were previously studied with *in vivo*-passaged tumours and with TB-1 as cultured cells[3]. In addition to Thy-1 and Lyt, characteristic T-cell markers[4], these tumours were observed, through the use of immunofluorescence, intermittently to have surface (but not intracellular) immunoglobulins, Ia, and Fc receptor, considered characteristics of B cells[5]. We verified that virtually all cells of the cytotoxic cultured lines used in the present study could be lysed specifically by anti-Thy-1.1 antibody[6] (plus complement); we are re-investigating whether they synthesise immunoglobulin. The Lyt antigens and the crawling activity of all the tumours listed in Table 1 will be reported elsewhere (T.W.C., E. Celis, P. D. Gottlieb, F. Solomon and H.N.E., in preparation). Tentatively, it seems that all the killer cells have crawling activity, but that some crawlers are not cytotoxic[1].

Previous studies indicate that lysis of target cells in the presence of Con A or phytohaemagglutinin is due to cytotoxic T cells, not to other activated T cells[7], and that the same lytic mechanisms are involved in Con A-dependent and antigen-dependent target cell lysis[8]. Other evidence, however, indicates that the T cells engaged in Con A-dependent killing may lack specific receptors for antigen on target cells, while retaining the killing apparatus[9]. If specific receptors are absent, it may be possible to introduce them by fusing the immortal killer lymphomas with normal cytotoxic T lymphocytes of known specificity (or their precursors), just as myeloma cells have been fused with normal B lymphocytes to yield hybridomas that produce specific antibodies[10]. Cytotoxic T lymphomas are potentially useful for studying the cytolytic mechanism of killer lymphocytes and the properties of their antigen-recognition molecules.

Most mouse T lymphomas arise in the thymus, but the three cytotoxic lymphomas of Table 1 originated in the spleen or lymph nodes[3]. It may be more useful to look for additional killer T lymphomas among the rare lymphomas that seem to arise in relatively mature T-cell populations of spleen and lymph nodes than among the more common lymphomas that arise in the thymus. Lymphomas seem to appear with relatively high frequency in spleen and lymph nodes in old (>12 months) mice of the C58, B10.Y and HRS/J strains (H. Meier and W. B. Murphy, personal communications). Normal cytotoxic T cells, maintained in culture for long periods, are being evaluated as alternative sources of homogeneous killer cells. However, these normal cells require restimulation of T-cell factors for growth and for generation of cytolytic activity[11,12], and the quantity of cells that can be obtained is limited.

Dr M. Bevan provided the anti-Thy-1.1 antibody. We thank Drs M. Bevan, E. Celis, P. Gottlieb and F. Solomon for discussions, and various colleagues for contributions of tumour

The role of glucocorticoid receptor and gene expression in the anti-inflammatory action of dexamethasone

GLUCOCORTICOIDS are potent anti-inflammatory agents, but the molecular mechanisms involved in this activity are not yet understood. The biological actions of various steroid hormones have been shown to be mediated by functional proteins synthesised following translocation of a hormone-cytoplasmic receptor complex into the nucleus[1,2]. It is still not clear, however, whether the anti-inflammatory effects of glucocorticoids are mediate via binding to a cytoplasmic receptor in target cells and subsequent activation of gene expression[3], although glucocorticoid receptors have been demonstrated in HTC cells, liver[5], thymocytes[6] and lymphocytes[7]. The results reported here suggest that a glucocorticoid receptor and the induction of gene expression are involved in the anti-inflammatory action of dexamethasone.

Experiments were undertaken to determine (1) whether progesterone, fluoxymesterone and 17α-methyltestosterone (designated by Samuels and Tomkins[8] as 'anti-inducers' on the basis of their antagonism of corticoid induction of tyrosine aminotransferase in hepatoma tissue culture cells) interfere with anti-inflammatory action of dexamethasone and (2) whether RNA and protein synthesis is essential for the manifestation of the anti-inflammatory action of dexamethasone. Serotonin-induced footpad oedema in mice was used as a model of inflammation, since the mechanism of the vascular permeability increase in serotonin-induced inflammation has been well characterised[9].

An inflammatory response was induced by injecting serotonin (0.3 μg in 5 μl of *p*H 7.4 Tyrode's solution) in the subplantar region of the right foot of 6-week-old male ddY mice (25–30 g). The left foot was injected with Tyrode's solution only. Inflammatory response (oedema) was evaluated by measuring the difference in footpad thickness between right and left feet with a dial guage calliper 12 min after serotonin injection. The serotonin dose used was chosen on the basis of a dose-response curve obtained in preliminary experiments. Dexamethasone dissolved in ethanol/0.9% NaCl (1:39, v/v) was injected subcutaneously (s.c.) in the abdomen. Anti-inducer steroids were injected s.c. at a separate site on the abdomen.

Preliminary experiments suggested the existence of a time lag for manifestation of the anti-inflammatory effect of dexamethasone. To determine the appropriate dose for dexamethsone as inhibitor of serotonin-induced inflammation, dexamethasone was given at 0.15, 0.5 and 1.5 mg per kg body weight. There was significant inhibition of inflammation at 0.5 and 1.5 mg per kg (65 and 78% inhibition respectively). Using a dexamethasone dose of 0.5 mg per kg the inflammatory lesion was induced at various times after dexamethasone treatment. Dexamethasone did not inhibit serotonin-induced inflammation within 1 h after administration, but the anti-inflammatory effect was apparent at 2 h, reached a maximum at 3 h and persisted for 6 h or longer. Based on these results, the inflammatory lesion was provoked in all of the following experiments 2.5–6 h after injection of dexamethasone.

In the first series of experiments for anti-inducer compounds (Table 1), the test compounds were given 1 h before dexamethasone and footpad inflammation was provoked 3 h after dexamethasone injection. A single treatment with dexamethasone caused a marked reduction of the inflammatory response. Progesterone, fluoxymesterone and 17α-methyltestosterone, when applied before dexamethasone treatment, brought about a marked inhibition of the anti-inflammatory effect of dexamethasone. The degree of the inhibition was dose-dependent, and complete blockade of the anti-inflammatory action was observed with all three anti-inducer steroids at doses of 200 mg per kg. Treatment with these non-corticoid anti-inducer steroids alone exerted no appreciable influence on the serotonin-induced inflammatory response. On the other hand, androstenedione, was classified as an inactive compound by Tomkins *et al.*[8] exerted no detectable influence on either the inflammatory response to serotonin or the anti-inflammatory action of dexamethasone (Table 1, series 1).

Similarity between the ability of the anti-inducer steroids to block anti-inflammatory action of dexamethasone and their ability to inhibit both glucocorticoid induction of tyrosine aminotransferase and glucocorticoid binding with the specific receptor in HTC cells suggests that similar mechanisms may be involved in these processes. If binding of glucocorticoid to specific receptor, and subsequent transfer of the corticoid–receptor complex into the nucleus are essential components of anti-inflammatory corticoid effects, the application of an inhibitor of corticoid–receptor binding after the corticoid–receptor complex has been transferred into nucleus would not block the final effects of the corticoid. To examine such possibilities, the second series of experiments was performed. An anti-inducer steroid 17α-methyltestosterone was given 1 h after dexamethasone treatment and serotonin was injected 3 h after dexamethasone to induce inflammation. The results are presented in Table 1 (series 2). Administration of the anti-inducer steroid at this late stage exerted no detectable influence on the anti-inflammatory action of dexamethasone. Thus 17α-methyltestosterone inhibits glucocorticoid action by blocking exclusively an early step in the series of reactions which leads to the anti-inflammatory effect. Antagonism of some steroidal compounds to various biological effects of the corticoids has been described in HTC cells[4,8], skeletal muscle[10] and thymocytes[6], and discussed in relation to their ability to

In series 1 experiments, non-corticoidal steroids were given s.c. 1 h before s.c. injection of dexamethasone. Serotonin-footpad-oedema was provoked 3 h after the dexamethasone treatment. In series 2, 17α-methyltestosterone was injected s.c. 1 h after application of dexamethasone. Serotonin-footpad oedema was induced 3 h after the dexamethasone treatment. The oedema was expressed in terms of the increase in the footpad thickness and the values represent means of seven or eight mice ± s.e.m.

Oedema (mm)	0.47 ± 0.058	0.15 ± 0.015*	0.44 ± 0.036†	0.41 ± 0.036†			2.5

In series 1, cycloheximide and actinomycin D were given s.c., twice, simultaneously and 1.5 h after s.c. injection of dexamethasone. Serotonin-footpad oedema was provoked 3 h after the injection of dexamethasone. In series 2, cycloheximide was applied, twice, at 3 and 4.5 h after the application of dexamethasone and the serotonin oedema was induced 6 h after the dexamethasone injection. In series 3, cycloheximide was given 1 h after the dexamethasone treatment and the serotonin oedema was induced 2.5 h after the dexamethasone injection. Amounts of cycloheximide and actinomycin D used were sufficient to inhibit RNA and protein synthesis[11–13].

†Statistically significant differences with respect to dexamethasone group, $P < 0.01$.

compete with glucocorticoids in binding with the specific receptor in target cells. Our demonstration of antagonism by 'anti-inducer steroids' of the anti-inflammatory action of the corticoid suggests a role for corticoid receptor in the anti-inflammatory action of the corticoid. It will be difficult, however, to directly demonstrate antagonism at the receptor site because it is not clear which are the primary target cells in the anti-inflammatory action of the corticoid.

To test for the requirement for RNA and protein synthesis, actinomycin D or cycloheximide[11–13] was given twice, simultaneously with dexamethasone and 1.5 h later, in an attempt to inhibit RNA or protein synthesis for 3 h consecutively after the application of dexamethasone. The results summarised in Table 2 (series 1) clearly indicate that the anti-inflammatory effect of dexamethasone is completely blocked by actinomycin D or cycloheximide, suggesting a requirement for synthesis of new

RNA and protein. To establish whether uninterrupted protein synthesis throughout experimental periods is essential, mice were injected with cycloheximide 3 and 4.5 h after application of dexamethasone in an attempt to block protein synthesis for the period from 3 to 6 h after dexamethasone treatment. The inflammatory lesion was provoked at 6 h after the dexamethasone treatment. Cycloheximide given at this stage did not block the anti-inflammatory action of the steroid (Table 2, series 2). Further experiments were performed to characterise the mechanism of the effect of cycloheximide injected 1 h after application of dexamethasone: When serotonin footpad oedema was induced 1.5 h after application of cycloheximide there was complete blockade of the anti-exudative effect of dexamethasone (Table 2, series 3).

For several of the metabolic effects of glucocorticoids a latency period of 0.5–2 h has been reported[14]. These time lags probably represent time required for events subsequent to entering of the corticoid into target cells to bring about production of specific protein through gene expression. A similar time lag has been reported[15] for the inhibitory effect of dexamethasone against experimental anaphylaxis and histamine-induced inflammatory reactions in rat and mice. In agreement with these observations, a latency period of 1–2 h was observed in the present experiments with respect to manifestation of the anti-inflammatory action of dexamethasone. When actinomycin D or cycloheximide was applied simultaneously (Table 2, series 1) with dexamethasone or during the latency period (Table 2, series 3), the anti-inflammatory effect of the steroid was abolished. Therefore, both RNA and protein synthesis appear to be essential for manifestation of the anti-inflammatory activity of dexamethasone. However, as the anti-inflammatory effect of the steroid was not affected by cycloheximide applied 3 h after administration of the steroid (Table 2, series 2), it is not essential that protein synthesis proceeds without interruption over the entire period. It is likely, therefore, that new RNA and protein synthesised under the influence of dexamethasone play an essential role in the manifestation of the anti-inflammatory activity.

During preparation of this paper Flower and Blackwell reported evidence of induction in the guinea pig lung by glucocorticoids of biosynthesis of a protein (or peptide) inhibitor which prevents protaglandin generation[16]. It is possible that similar mechanisms might underlie the inhibitory action of dexamethasone against serotonin-induced inflammatory response, since serotonin stimulates some tissues to generation of rabbit aorta contracting substances (a mixture of prostaglandin endoperoxides and thromboxane A_2)[17]. However, the finding that indomethacin does not affect serotonin-induced paw oedema in rats[18] suggests that serotonin provokes an inflammatory response independently of the prostaglandin and thromboxane generation system. We also confirmed that indomethacin was inert in inhibiting mice footpad oedemata induced by various phlogistic agents such as serotonin, bradykinin and PGE_1, whereas dexamethasone suppressed all of them. It is therefore likely that dexamethasone displays anti-inflammatory action, apart from phospholipase inhibition[16], through direct suppression of endothelial cell contraction induced by chemical mediators such as serotonin[9].

A new proposal regarding the subunit composition of $(Na^+ + K^+)$ATPase

THREE types of high affinity ligands are available for studies with $(Na^+ + K^+)$ATPase: nucleotide substrates, vanadate and ouabain. Of these, the last is unique in apparently being absolutely specific for $(Na^+ + K^+)$ATPase. One of the generally accepted facts regarding $(Na^+ + K^+)$ATPase is that there are equal numbers of measurable (high affinity) binding sites for ATP and ouabain per molecule of enzyme[1–5]. There is a majority opinion that direct binding experiments yield binding capacities for these ligands of 1 mol site per 250–300 kg protein in the purest preparations available[3,6–8]. From these data, from determinations of the peptide composition and from estimates of the apparent molecular weight of solubilised enzyme the idea of $(Na^+ + K^+)$ATPase as a dimer (with respect to the large, so-called catalytic, peptide) has emerged[9–14]. Such a dimer would have one high affinity binding site for nucleotide and one for ouabain. The present report on binding site determinations on mammalian kidney microsomes before and after detergent treatment casts serious doubts on the general validity of the above simple relationship between sites and peptide composition.

The essential points of this report are represented in Figs 1 and 2. Figures 1 and 2*b* show that, in agreement with what has been outlined above, detergent-treated kidney microsomes have an equal number of high affinity nucleotide-binding sites and of ATP-supported ouabain-binding sites and P_i-supported ouabain-binding sites. The number of vanadate-binding sites happens also to be the same, contrary to the findings of Cantley *et al.*[5].

If one turns to the source of these enzyme preparations, that is, crude microsomal fraction from pig kidney outer medulla, it can be seen that this simple stoichiometry no longer holds (Table 1 and Fig. 2*a*). The microsomes have equal capacities for binding nucleotide and vanadate and for ATP-supported ouabain binding, but capacities exactly twice as large for both P_i-supported ouabain binding and for vanadate-supported ouabain binding.

The complexity of the situation is further stressed by the curvature of the isotherms for nucleotide binding, vanadate binding, and ATP-supported ouabain binding (Fig. 2*a*). Such curvature is diagnostic of an inhomogeneity in the site populations[21,22]. On the assumption that the observed inhomogeneity is due to a mixture of only two populations of sites, non-linear regression analysis of the data[23] strongly suggests that for all three ligands the two populations are of identical size (Table 1). This result is also mathematically compatible with a system of two inherently identical, negatively cooperating sites. The excellent fit of the calculated isotherms to the experimental data, as seen in Fig. 2*a*, makes it unnecessary to consider more complicated models at this point.

Obviously, some changes have occurred in the microsomal enzyme during or subsequent to detergent treatment. Figure 2*b* shows the results of binding studies made in the presence of those amounts of SDS added to the same microsomal

Table 1 Binding capacities for various ligands and K^+-dependent *p*-nitrophenyl phosphatase activities of microsomal $(Na^+ + K^+)$ATPase from pig kidney outer medulla before and after SDS treatment

Enzyme preparation	Relative ligand binding capacities*				Relative *p*-nitrophenyl phosphatase activity†	Mol *p*-nitrophenyl phosphate split per min per mol P_i-supported ouabain-binding site
	P_i-supported ouabain-binding capacity	Vanadate-supported ouabain-binding capacity	Nucleotide-binding capacity, vanadate-binding capacity, and ouabain-binding capacity (ATP-supported) Total	Subpopulations		
Microsomes	4	4.0	2.0	1.07 & 0.93	1	0.39×10^3
		4.0	2.0	0.96 & 1.04		0.41×10^3
Microsomes + SDS	4.1	—	4.0	None apparent	3.9	1.53×10^3
	3.9		4.0		3.9	1.59×10^3
Purified enzyme preparations						1.49×10^3
						1.52×10^3

The table shows values obtained with two separate microsome preparations before and after addition of SDS.
* Values are expressed relative to P_i-supported ouabain-binding capacity of untreated microsomes. This we define as being equal to 4.
† Relative to that of untreated microsomes.

preparation of Fig. 2*a* so as to yield maximal *p*-nitrophenyl phosphatase activity. It can be seen (see also Table 1) that the SDS-treated microsomal enzyme has equal binding capacities for each of the ligands tested; that the P_i-supported ouabain-binding capacity has not changed; that *p*-nitrophenyl phosphatase activity has quadrupled; and that the molar activity of the phosphatase is identical to that of enzyme purified through SDS treatment. In other words, the enzyme has now been converted to the same state as found in purified (and pure) preparations. And pure preparations of $(Na^+ + K^+)$ATPase contain one ouabain-binding site and one nucleotide-binding site per two large, catalytic peptides. As the P_i-supported ouabain-binding capacity of the enzyme remains unchanged with SDS treatment, it must be concluded that untreated microsomes have one P_i-supported ouabain-binding site per two large peptides.

As microsomes have one nucleotide-binding site and one vanadate-binding site per two P_i-supported ouabain-binding sites, two conclusions are possible at this stage. (1) In microsomes there exists a mixture of exactly equal amounts of two types of enzyme, each containing two large peptides and one P_i-supported ouabain-binding site. One nucleotide-binding site and one vanadate-binding site must then be distributed between the two types of enzyme. (2) Microsomal $(Na^+ + K^+)$ATPase contains four large peptides per molecule, with two P_i-supported ouabain-binding sites, one nucleotide-binding site and one vanadate-binding site. The fact that protein with one vanadate-binding site has two vanadate-supported ouabain-binding sites (Fig. 2*a* and Table 1) makes the choice of an ATPase molecule with four large peptides obvious at this point. However, in microsomes the nucleotide-binding sites, the vanadate-binding sites and the ATP-supported ouabain-binding sites all seem to be distributed among two populations of identical size (Table 1). It therefore becomes necessary once again to make a choice between two possibilities. (1) In microsomes there are identical amounts of two different enzymes, each with one nucleotide-binding site, one vanadate-binding site and two P_i-supported ouabain-binding sites per molecule. (2) Microsomal $(Na^+ + K^+)$ATPase has four P_i-supported ouabain-binding sites, two nucleotide-binding sites and two vanadate-binding sites per molecule.

A choice can be made on the basis of the following arguments. Treatment of microsomes with SDS converts the curved binding isotherms of Fig. 2*a* into straight lines (Fig. 2*b*). This suggests that the inhomogeneity of the microsomal site populations was a consequence of interactions between pairs of inherently identical sites (for example, negative cooperativity)[24,25], and that treatment with SDS has disrupted the interaction.

We will disregard the possibility that it is due to chance alone that in microsomes there are equal amounts of two types of nucleotide-binding site—vanadate-binding sites and ATP-supported ouabain-binding site—and exactly twice as many P_i-supported ouabain-binding sites and vanadate-supported ouabain-binding sites; and that SDS treatment exactly doubles the number of the former sites and quadruples the *p*-nitrophenyl phosphatase activity. Thus, for example, we deem it unlikely that one can reproducibly prepare microsomes containing appropriate proportions of inside-out, right-side-out and open vesicles with peculiar permeabilities. We must therefore choose the second possibility mentioned above, and conclude that native $(Na^+ + K^+)$ATPase as found in pig kidney microsomal preparations from the outer medulla seems to be a molecule containing eight large, catalytic peptides with four

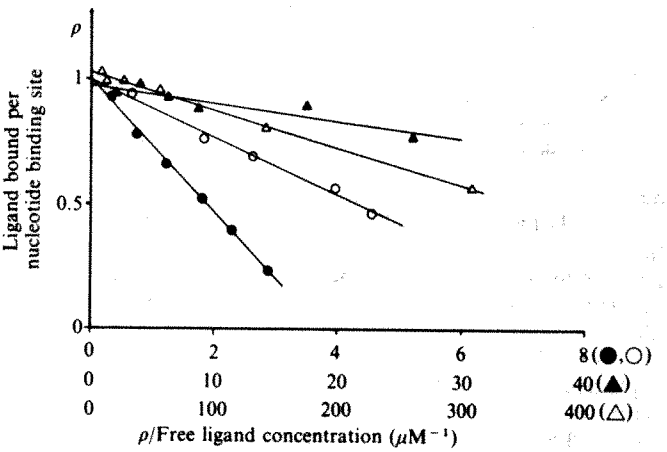

Fig. 1 Scatchard plots of data of equilibrium binding of ^{14}C-ATP (○), ^{14}C-ADP (●), ^{48}V-vanadate (▲) and of ^{3}H-ouabain (as supported by P_i) (△) to a purified preparation of $(Na^+ + K^+)$ATPase from pig kidney outer medulla. The intercepts on the ordinate, calculated by linear regression analysis, give a measure of the total ligand capacities. The numerical value of each slope is equal to the dissociation constant of the ligand in question. The enzyme was prepared as described by Jørgensen[15], except that ATP was omitted from the SDS activation medium. $(Na^+ + K^+)$ATPase activity (assayed according to Nørby[16]): 12.7 μmol substrate split per min per mg protein. K^+-dependent *p*-nitrophenyl phosphatase activity (assayed according to Skou[17]): 2.3 μmol substrate split per min per mg protein. Nucleotide binding was measured by the method of Nørby and Jensen[18]. P_i-supported ouabain binding was carried out according to Hansen[19] in the presence of 3 mM Mg^{2+}, 3 mM P_i and 40 mM Tris-HCl (*p*H 7.25, 37 °C). A similar filtration method was used for determinations of vanadate binding, after incubation of enzyme with varying concentrations of ^{48}V-vanadate for 60 min at 25 °C with 5 mM Mg^{2+}, 10 mM K^+ and 40 mM Tris-HCl (*p*H 7.25). ^{48}V-vanadate was from the Radiochemical Centre, Amersham and was diluted with orthovanadate obtained by dissolving $NaVO_3$ in NaOH.

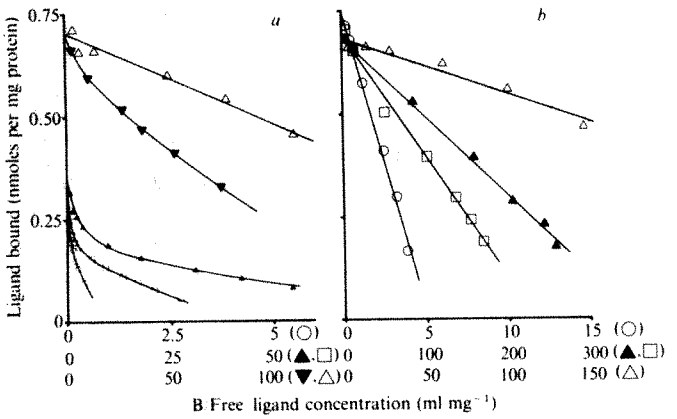

Fig. 2 Scatchard plots of data of equilibrium binding of ^{14}C-ATP (○), ^{48}V-vanadate (▲), ^{3}H-ouabain as supported by P_i (△), by vanadate (▼) and by ATP (□) to pig kidney microsomal ($Na^+ + K^+$)ATPase prepared according to the first steps of Jørgensen's procedure[15]. Total ligand binding capacities can be obtained from intercepts of the curved plots with the ordinate. Non-linear regression as described in the text was used for an analysis of these curves. For the straight line plots, see text to Fig. 1. *a*, Microsomes before SDS treatment. ($Na^+ + K^+$)ATPase activity: 1.18 μmol ATP split per min per mg protein. K^+-*p*-nitrophenyl phosphatase activity: 0.31 μmol substrate split per min per mg protein. *b*, Same microsomal preparation after SDS treatment. Microsomes suspended at a concentration of about 4 mg protein ml^{-1} in 250 mM sucrose, 30 mM imidazole and 0.06 mM EDTA (*p*H 7.2, 20 °C), were treated for 20 h at room temperature with 0.06% SDS (stable, maximal K^+-*p*-nitrophenyl phosphatase activity was obtained in these conditions). ($Na^+ + K^+$)ATPase activity: 6.30 μmol ATP split per min per mg protein. K^+-*p*-nitrophenyl phosphatase activity: 1.19 μmol substrate split per min per mg protein. Binding of ligands was carried out in the presence of the added SDS. ATP-supported ouabain binding took place in the presence of 3 mM Mg^{2+}, 120 mM Na^+, 3 mM ATP and 40 mM Tris-HCl (*p*H 7.25, 37 °C). Vanadate-supported ouabain binding took place in the presence of 3 mM Mg^{2+}, 40 mM Tris-HCl and 10 μM vanadate[20]. Other procedures were those listed in Fig. 1.

ouabain-binding sites and four nucleotide-binding sites. Of the latter, only two are available for binding substrate at any one time, that is, there is total negative cooperativity between two pairs of such sites. The nucleotide-binding sites and ouabain-binding sites would be distributed most reasonably on four identical subunits containing two large peptides each.

The result of treatment of microsomes with SDS could be explained as a relaxation of two different and coexistent interactions: the total negative cooperativity between pairs of sites and another, less overwhelming, interaction within pairs of sites. The conversion of one molecule of enzyme into four more-or-less independent subunits would be reasonable grounds for the quadrupling of *p*-nitrophenyl phosphatase activity that accompanies SDS treatment.

If the effects of SDS described in the present report are not due to a trivial artefact, and if they can be duplicated (by whatever physiological mechanism) *in vivo*, the proposed changes in interaction between four functional subunits of ($Na^+ + K^+$)ATPase would allow for a wide range in the regulation of the activity of the enzyme and, therefore, of the sodium pump.

We thank Ms Edith Møller and Ms Kirsten Pedersen for technical assistance and Toke Nørby for help with the computation tasks.

Semi-synthesis of human insulin by trypsin-catalysed replacement of Ala-B30 by Thr in porcine insulin

HUMAN insulin differs from porcine insulin by a single amino acid (Thr instead of Ala) at the C-terminal residue of the B-chain. Inouye *et al.*[1] have established a procedure for the semi-synthesis of human insulin, in which trypsin is used as a catalyst for the coupling of desoctapeptide-(B23–B30)-insulin (DOI) with a synthetic octapeptide corresponding to positions B23–B30 of human insulin. DOI was prepared by tryptic digestion of porcine insulin. The enzymatic method has many advantages, in particular, better yields and simple operation, over the chemical methods originally used by Ruttenberg[2] and Obermeier and Geiger[3]. Here we report a more simple and economical method for the semi-synthesis, in which trypsin can catalyse the coupling between desalanine-B30-insulin (DAI) and Thr-OBu^t to generate human insulin in good yield.

DAI was obtained by digestion of porcine insulin with carboxypeptidase A (E/S = 1/100, in weight) for 8 h at 25 °C in the presence of 0.1 M NH_4HCO_3 (*p*H 8.3)[4]. Trypsin-catalysed coupling of DAI and Thr-OBu^t was determined quantitatively using a reverse-phase liquid chromatography (LC) system (for conditions, see Fig. 1), in which the ratio of [Thr-OBu^t-B30]-insulin produced to the remaining DAI was determined from their peak areas and intensity factors. A preliminary experiment indicated that the coupling occurred with a large excess of the amine component (Thr-OBu^t) in the presence of high concentrations of organic co-solvents. The significance of these co-solvents in coupling has been described previously[1,5,6]. To our surprise, there was no splitting of the Arg(B22)–Gly(B23) bond in DAI or the product; this was expected to be a problem, and has previously been thought to occur through the hydrolytic activity of trypsin.

Preparative-scale coupling was carried out as follows. 0.7 ml of 0.5 M Tris buffer containing trypsin (recrystallised three times; 4.1 mg, 0.1 mM), final *p*H 6.5, was added to a 1.05 ml solution of DAI (100 mg, 10 mM) and Thr-OBu^t (205 mg, 0.5 M) in a mixture of dimethylformamide and ethanol (1/1 by volume), and the reaction mixture was kept at 37 °C for 20 h. LC showed that 73% of the DAI had been converted into the product. The reaction mixture was applied to a column (3.2 × 41 cm) of Sephadex G-50 (super fine) and eluted with 0.5 M

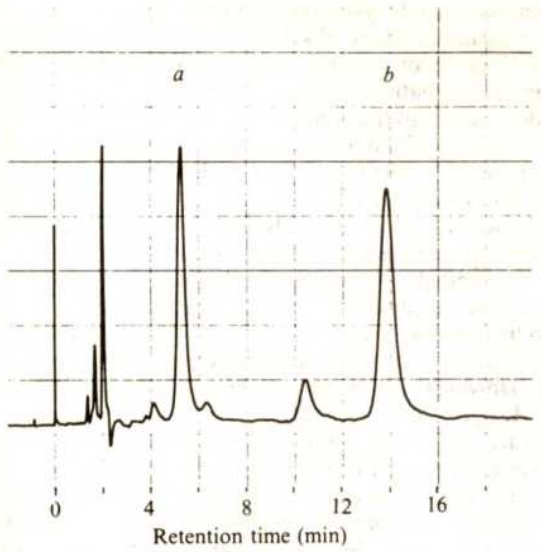

Fig. 1 Liquid chromatogram of porcine DAI (*a*) and [Thr-OBu^t-B30]-porcine insulin (*b*): column, Nucleosil 5 C_{18}, 0.4×20 cm; eluant, 30.5% CH_3CN in 5 mM phosphate buffer (*p*H 3.0) containing 5 mM n-$BuSO_3Na$ and 50 mM Na_2SO_4; detection at 220 nm.

acetic acid. Three fractions corresponding to trypsin, insulin or its derivatives, and Thr-OBu^t were successively eluted. The fraction corresponding to insulin or its derivatives was lyophilised (89 mg), and then applied to a column of DEAE-Sephadex A-25 (2×20 cm) which had been equilibrated with 0.01 M Tris buffer (*p*H 7.4) and 7 M urea. A linear Na^+ gradient (to 0.3 M NaCl) was begun at 4 °C according to the method of Bromer and Chance[7]. The first peak (35 mg) corresponded to [Thr-OBu^t-B30]-insulin and the second one (27 mg) to DAI and/or intact insulin (Figs 1, 2).

[Thr-OBu^t-B30]-insulin was treated for deprotection with trifluoroacetic acid in the presence of anisole. The yield was 41% (32 mg) based on the assumption that the purity of DAI used as the starting material was 78%, which had been deduced from its amino acid composition. This semi-synthetic human insulin was homogeneous according to LC[1] and polyacrylamide gel electrophoresis (Fig. 2). Amino acid analysis (theoretical values in parentheses) gave: Lys 1.00 (1), His 1.89 (2), Arg 0.87 (1), Asp 3.32 (3), Thr 3.16 (3), Ser 2.99 (3), Glu 7.35 (7), Pro 1.29 (1), Gly 4.39 (4), Ala 1.26 (1), $CySO_3H$ 5.38 (6), Val 3.93 (4), Ile 1.61 (2), Leu 6.51 (6), Tyr 3.68 (4), and Phe 3.19 (3). In the bioassay for hypoglycaemic activity, no significant difference was observed between the semi-synthetic human insulin and porcine insulin.

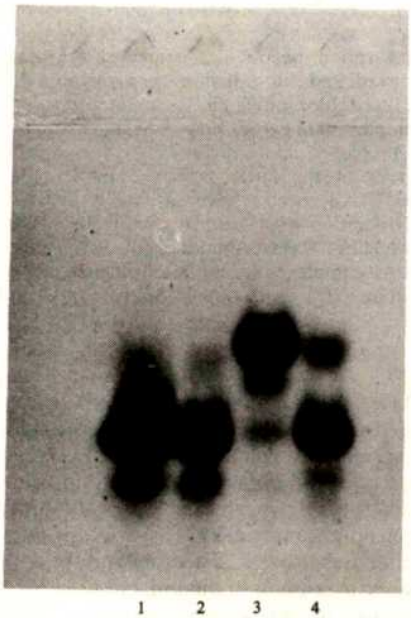

Fig. 2 Polyacrylamide gel electrophoresis of insulins (*p*H 8.0, 10% gel): 1, porcine insulin; 2, porcine DAI; 3, [Thr-OBu^t-B30]-porcine insulin; 4, semi-synthetic human insulin.

A similar preparative-scale experiment was carried out using DAI (5 mM) prepared from bovine insulin in the above conditions except that the enzyme concentration was 1 mM. LC showed that 80% of DAI had been converted into the product. The product was isolated by the above method, and pure semi-synthetic [Thr-B30]-bovine insulin was obtained in 60% yield.

The present study indicates that an enzymatic coupling system is a useful means of semi-synthesis of biologically active products, with either one or both component(s) starting from natural materials of very large molecular weight. Unlike conditions for chemical methods, for enzymatic methods functional groups in the starting materials may not need to be blocked. We must also stress that the hydrolytic activity of proteases used as a coupler is minimal in conditions suitable for synthesis, that is, in the presence of high concentrations of organic solvent and the amine or carboxyl component to be coupled.

We thank Drs Y. Tochino and T. Kanaya for doing the bioassay for the hypoglycaemic activity of insulin, and Drs S. Sakakibara and K. Inouye for their interest and encouragement throughout this work.

Chlorophyllin–apomyoglobin complexes

CHLOROPHYLL (Chl), *in vivo* as well as in protein complexes purified from photosynthetic organisms, absorbs light at longer wavelengths than does Chl as an isolated molecule in an organic solvent[1]. These bathochromic absorbance shifts are substantial, up to 40 nm (800 cm^{-1}) for Chl *a* in green plants and 100 nm (1,400 cm^{-1}) for bacteriochlorophyll (Bchl) *a* in photosynthetic bacteria. An important question is whether these shifts are caused largely by Chl–Chl interactions or by interactions between Chl and the proteins to which all Chl is bound *in vivo*[2–4]. This has been difficult to answer because no native Chl–protein complex yet found contains only one pigment molecule. We report here, substituting the water-soluble Chl derivative, chlorophyllin (Chln) *a*, for haem in myoglobin, and irradiating the resultant complex with red light, the first model Chl–protein complex that verifiably contains a single pigment molecule and that also exhibits a 1,000 cm^{-1} bathochromic shift in absorbance.

For protein-free model Chl dimers in which bathochromic absorbance shifts are also observed, explanations of the shift energy have been based in part on the resonance (exciton) interaction between the electronic transitions of the two closely

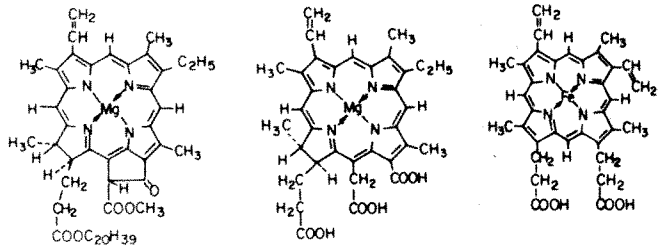

Fig. 1 Structure of (left to right): Chlorophyll *a*, Mg chlorin e_6 (chlorophyllin *a*), and Fe protoporphyrin IX (haem).

spaced Chl molecules[5]. A recent theoretical analysis attributes nearly half the shift energy to the exciton interaction[6]. But for two different Bchl–protein complexes about whose structure something is known[7,8], exciton interactions account in one case[7] for only a quarter of the shift[9] and in the other[8,10] for none of it. In choosing myoglobin as our model protein, we were guided by specific findings on these two complexes. The Bchl *a*-protein from *Prosthecochloris aestuarii* is the only native complex whose structure has been determined by X-ray crystallography[7]. The Mg atoms of all 21 of its Bchl molecules are 5-coordinate; for 5/7 of the Bchls the fifth ligand of the Mg is histidine[11]. The other is a 22,000 molecular weight purple bacterial complex (from *Rhodopseudomonas sphaeroides* R-26) that contains only two pigment molecules[8]. In this remarkable complex, the centroid of the CD spectrum is bathochromically shifted by 1,300 cm^{-1} (relative to Bchl *a* in ether[12]), occurring at a slightly longer wavelength than that of the absorbance peak. Theoretically, in an aggregate that contains only two chromophores, the centroid of the conservative CD band, which results from the exciton interaction, occurs at the wavelength where absorbance would be maximal in the absence of that interaction[13]. Thus, analysis of the spectra of this two-pigment complex shows that in it the exciton interaction causes a small hypsochromic shift in absorbance—the entire 1,300-cm^{-1} shift is unexplained.

In light of these considerations, apomyoglobin is almost ideally suitable as a model protein. Myoglobin itself is a small protein, and its structure is very well known from X-ray crystallography[14]. Its native prosthetic group, haem, is easily removed and can be replaced by another porphyrin[15]. In deoxymyoglobin the haem Fe atom is 5-coordinate, the fifth ligand being histidine. Also, nonspecific porphyrin–apomyoglobin binding seems unlikely. We used Breslow's method[16] to prepare apomyoglobin from sperm whale myoglobin (Sigma), and subsequently purified the apoprotein by gel filtration chromatography using Sephadex G-75.

All the porphyrins so far substituted for haem in myoglobin or haemoglobin are, like haem and unlike Chl, water soluble. For simplicity, we chose to work with Mg chlorin e_6, a water-soluble derivative of Chl *a* commonly called chlorophyllin *a* (refs 17, 18) (Fig. 1). Chlorophyllin is Chl-like in that it has a central Mg atom and a reduced ring IV, but haem-like in having multiple carboxylates and no ring V. The structural differences between Chl *a* and Chln *a* cause only minor changes in the visible absorption spectra. We used an established procedure[17,19] to prepare Chln *a* from Chl *a* that was purified from spinach leaves by the method of Strain and Svec[20].

To prepare the complexes, Chln and apomyoglobin were mixed in 0.1 M borate buffer (*p*H 9.2)[16]. The freshly prepared mixture absorbs maximally at 644 nm, bathochromically shifted only very slightly compared with free Chln in the same buffer. (Figure 2 shows the various spectral forms of Chln–apomyoglobin mixtures.) When the mixture was irradiated with red light ($\lambda \geq 600$ nm), the 644-nm peak diminished, and a new peak appeared at 690 nm. (A similar peak has been observed for Chln bound to polyvinylpyrrolidone[17]. In this system, a peak at ~690 nm occurs slowly in the dark and more rapidly under red illumination. In our system the dark production rate is too small to be measured.) In the absence of O_2, the total absorbance in the red region of the spectrum is approximately conserved during the irradiation. The rate of photoconversion is temperature dependent; in the conditions used here it required ~2 h at 22 °C, while at 5 °C it was too slow to observe conveniently. In the dark at 22 °C, the 690-nm peak disappeared in a few tens of hours, and was replaced by a peak at 646 nm. Again, total red absorbance was approximately conserved, although this dark relaxation process is O_2 independent. At 5 °C, the dark relaxation proceeded ~10 times more slowly. In contrast to the original 644-nm absorbing form, the 646-nm form is insensitive to red light in the absence of O_2. The occurrence of the relaxed form apparently limits the photoconversion yield of the 690-nm form. However, we readily achieved an absorbance ratio, A_{690}/A_{645}, of 1.1.

Freshly prepared, irradiated and irradiated-and-relaxed samples (2 ml) of Chln–apomyoglobin mixtures were chromatographed separately on 1 × 50 cm Sephadex G-75 columns at 5 °C. In each case, protein and pigment co-eluted at a volume corresponding to the molecular weight of myoglobin

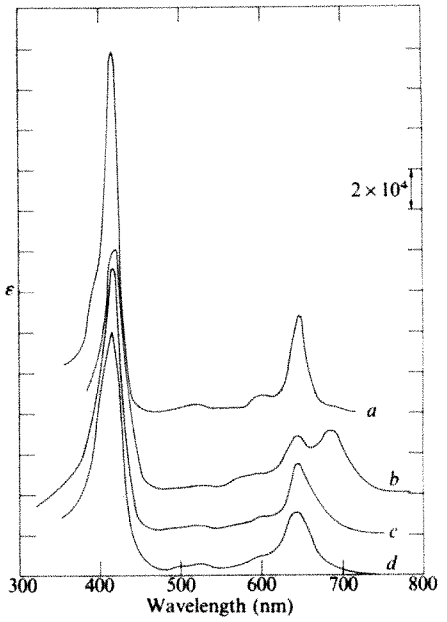

Fig. 2 Absorption spectra of: a, irradiated and relaxed; b, irradiated; c, unirradiated chlorophyllin–apomyoglobin complexes; and d, uncomplexed chlorophyllin *a*. The extinction coefficients for the protein complexes are expressed per mol apomyoglobin, and those for the uncomplexed chlorophyllin are expressed per mol pigment; the spectrum of the latter is scaled by Broyde's extinction coefficients[19]. All spectra have essentially zero absorbance at 800 nm. Irradiation is performed with a 75 W Xe lamp and a Corning 2-63 filter. Relaxed material remained in the dark at 22 °C for 7 days. All complexes are chromatographed on Sephadex G-75 and have 1:1 stoichiometry of pigment to protein.

(~18,000 MW), demonstrating that a complex was formed. Uncomplexed pigment eluted in much later fractions. Protein concentration was determined in the fractions by Lowry's procedure[21], using an equimolar mixture of Chln and apomyoglobin as a standard (pigment correction, 15%). Pigment was determined spectrophotometrically for the protein complex in aqueous buffer and also in 7:2 acetone/methanol solutions. The red absorbance maximum of the unirradiated complex (644-nm form) differs little in wavelength or extinction from that of Chln in buffer. The stoichiometry of this complex in ~18,000-MW fractions taken from the column is 1.0 ± 0.1 pigment molecule per protein when either 1.2:1 or 4:1 mixtures of pig-

ment/protein are loaded onto it. Because the red absorption of the complex is substantially changed on irradiation, the pigment content of both irradiated and irradiated-and-relaxed samples was estimated by assuming that the extinction coefficient at the maximum of the Soret band (~420 nm) is unchanged. On this basis, a stoichiometry of 1.1 ± 0.1 pigment per apomyoglobin in 18,000-MW fractions was found when either 1.2:1 or 3:1 mixtures of pigment/protein were irradiated and then chromatographed. The irradiated-and-relaxed complex has a stoichiometry of 1.2 ± 0.2 pigment per protein. The independence of the final stoichiometries from those in the initial mixtures is further substantiated by the constancy of the ratios of red band to Soret to protein tryptophan absorbance maxima in corresponding fractions of the two chromatographies. These results demonstrate the monomeric nature of the 690-nm absorbing Chln derivative that is formed as an apomyoglobin complex.

It is likely, though not proved, that other 690-nm absorbing forms of Chln, previously observed in protein-free systems and assumed to be aggregated forms of Chln[17,22] are also monomeric. In control experiments on irradiated Chln in protein-free borate buffer, a presumably monomeric 690-nm absorbing form is observed, together with a highly aggregated form of Chln that absorbs at 735 nm (Davis and Pearlstein, unpublished results). The latter form has also been observed in other protein-free Chln systems[17,22], but does not appear in solutions of apomyoglobin complexes.

The 690-nm monomer remains to be chemically identified. The close similarity of the absorbance spectra of the unirradiated and the irradiated-and-relaxed apomyoglobin complexes suggests that the chemical differences between these two are slight, and places a considerable constraint on the nature of the 690-nm form. The evidence suggests that the transformation to the 690-nm form is a property of the Chln itself. Although we do not know what this property is, one possibility is that it represents deformations of the Chln macrocycle that result from changes in axial ligation of the central Mg.

In conclusion, we have produced 1:1 complexes of apomyoglobin with the water-soluble chlorophyll derivative, chlorophyllin, that exhibit three spectral forms including one that, like chlorophyll *in vivo*, absorbs light at long wavelengths.

We thank W. B. Whitten for valuable discussions and N. A. Edie for expert technical assistance. This work was supported by Battelle Memorial Institute.

An inhibitor protein of nuclear protein kinases

THE cyclical phosphorylation and dephosphorylation of proteins, catalysed by protein kinases and phosphoprotein phosphatases, respectively, are important ways in which cells regulate many of their metabolic activities. Cells seem to have at least two distinct phosphorylation systems, one in the cytoplasm, the other in the nucleus. The best studied function of the cytoplasmic protein kinases is their mediation of the effects of cyclic AMP in the modulation of existing metabolic pathways, whereas the nuclear protein kinases have been implicated in the regulation of gene activation[1]. This view is based on the rapid changes in nuclear protein phosphorylation that occur in response to stimuli of differentiation and cell growth[2–4], and because phosphorylated proteins are heavily concentrated in the actively transcribed regions of the genome[5]. For these reasons the nuclear protein kinases have been studied extensively, yet there is very little information concerning their regulation. It is thus of considerable interest to identify the proximal effectors of nuclear protein phosphorylation. We present here evidence for the presence in rat liver nuclei of a 150,000-molecular weight, heat-sensitive inhibitor protein that is specific for the nuclear protein kinases, being without effect on the cytoplasmic enzymes or their subunits. In addition to its potential importance as a negative regulator of nuclear protein kinases, the inhibitor may prove to be a valuable tool in assessing the role of nuclear protein phosphorylation in gene activation.

The nuclear protein kinases exist in multiple molecular forms that can be separated on ion-exchangers[8–11]. Attempts to demonstrate a specificity of individual isoenzymes towards some of their natural substrates has remained inconclusive because of the difficulty of obtaining substrate-free enzyme and enzyme-free substrate preparations. We have used affinity chromatography, which achieves the selective removal of the protein kinases from their endogenous phosphate acceptors[12]. Briefly, the procedure is to pass a crude nuclear extract, prepared as previously described[12], through a casein–Sepharose column. At 0.1 M NaCl the protein kinases are selectively retained on the column whereas the bulk of the proteins passes unretarded through the gel and is collected in the effluent (fraction I). The enzymes are then eluted from the column in a highly purified state with 0.6 M NaCl (fraction II). Enzyme activity in fraction II is demonstrable only on addition of casein or fraction I as phosphate acceptors. When incubated separately with [γ-^{32}P]ATP and magnesium neither fraction incorporated phosphate into trichloroacetic acid (TCA) precipitable material, but incubation of the combined fractions gave the same activity as the original extract[12].

The enzymes, essentially substrate free (fraction II), were resolved by chromatography on phosphocellulose into several peaks of activity demonstrable using casein as phosphate acceptor, as previously described[6]. The column fractions within three major peaks containing protein kinase activity were pooled and concentrated severalfold by pressure dialysis, then incubated with and without the endogenous substrates (fraction I) concentrated to contain 5 mg per ml of protein. The total reaction mixtures were analysed by electrophoresis in SDS-containing polyacrylamide gels. The results are shown in Fig. 1. Figure 1*a* depicts the proteins stained with Coomassie Brilliant Blue, Fig. 1*b* shows the autoradiograph of the same gel, depicting the proteins phosphorylated by each isoenzyme in the presence ('a' channels) and in the absence ('b' channels) of 100 μg protein of fraction I. It can be seen that the proteins contaminating the protein kinases purified by affinity chromatography and phosphocellulose are present in quantities too small to be stained by Coomassie Blue or to register as phosphate acceptors in the standard protein kinase filter assay that measures TCA-precipitable ^{32}P. Nevertheless, these contaminants sustain sufficient phosphate incorporation to become visible when analysed by

© Macmillan Journals Ltd 1979

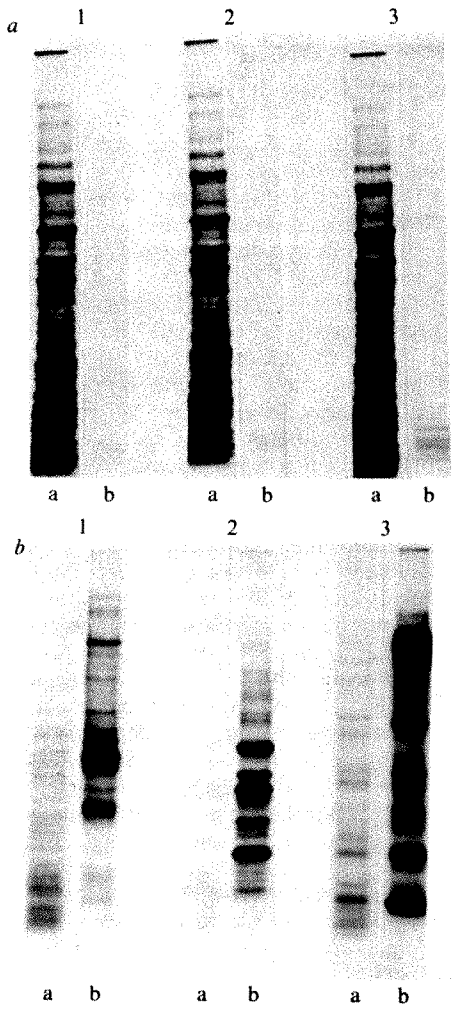

Fig. 1 Nuclear protein kinases were separated from their endogenous substrates by affinity chromatography[12] and separated into individual isoenzymes on phosphocellulose as previously described[6]. The active fractions within the three major peaks were pooled and concentrated by pressure dialysis. They were incubated for 20 min at 30 °C in 30 μl containing 3 μCi [γ-^{32}P]ATP and 15 nmol $MgCl_2$ in the presence ('a' channels) and in the absence ('b' channels) of 100 μg of enzyme-free concentrated fraction I. The reaction was stopped by addition of 3 μl 10% SDS and the entire reaction mixture was subjected to electrophoresis in SDS-containing polyacrylamide 7–15% gradient gels. The gels were stained with Coomassie Brilliant Blue to render the proteins visible (*a*), then dried and exposed for 16 h to NS 5T Kodak X-ray film (*b*). The twin-channels labelled 1, 2 and 3 refer to different isoenzymes.

autoradiography on gels after a 16-h exposure. It is clear that the latter detection method is considerably more sensitive than the filter assay. In the presence of 100 μg of protein in fraction I, however, phosphate incorporation is nearly abolished, whereas fraction I proteins supported significant phosphate incorporation when present at concentrations of 5–10 μg per assay. These results suggested that the fraction containing endogenous substrates also contained in inhibitor of protein kinase which, on concentration of crude, but enzyme-free, extracts severely inhibits phosphate incorporation into the natural substrates.

This preparation inhibited not only the phosphorylation of nuclear proteins but also that of casein. This permitted us to quantify the amounts of inhibitor present in nuclear extracts in the presence of saturating amounts of casein (1 mg per ml), thus eliminating the effects of varying amounts of endogenous substrates in the assay. Studies to characterise the inhibitor therefore measured the inhibition of casein phosphorylation. Figure 2 shows the inverse proportionality of remaining protein kinase activity with increasing amounts of inhibitor added to a constant amount (0.1 unit) of protein kinase purified by affinity chromatography[12]. One unit of inhibitor is defined as the amount giving 50% inhibition of 0.1–0.2 units of nuclear protein kinase in the standard assay[12].

Fraction I was adsorbed to a DEAE-cellulose column at 6 mg per ml of packed column volume in 50 mM Tris-HCl, *p*H 6.8, containing 0.1 M NaCl and 0.05% Nonidet P-40 (buffer I). Inhibitory activity eluted as a sharp peak between 0.3 and 0.35 M NaCl when the column was developed with a linear gradient in NaCl of 0.1–0.5 M in 50 mM Tris-HCl, *p*H 6.8, and 0.05% Nonidet P-40. The active fractions were pooled, concentrated by pressure dialysis and loaded onto a 0.6 × 50 cm column of Biogel P-150 (minus 400 wet mesh) equilibrated and developed in 50 mM Tris-HCl, *p*H 6.8, containing 0.5 M NaCl to minimise the possibility of molecular aggregation. The inhibitor emerged as a single, slightly skewed peak with an R_F of 0.9 relative to dextran blue, indicating an apparent molecular weight of 150,000. Inhibitory activity was destroyed on incubation at 60 °C for 10 min at *p*H 7 or at 37 °C for 30 min at *p*H 4. Incubation of the inhibitor with pancreatic RNase, DNase I or phospholipase A at 37 °C for 60 min had no effect, whereas incubation with trypsin or chymotrypsin rapidly destroyed its activity (data not shown).

Aliquots of an inhibitor preparation purified through the DEAE-cellulose step, containing 30–50 μg protein, induced 30–40% inhibition of each of the three major isoenzymes of nuclear protein kinase separated on phosphocellulose. However, they had no effect on the activity of a cytoplasmic protein kinase preparation (100,000*g* rat liver supernatant) either with casein or with histones as substrates, regardless of whether cyclic AMP was present in the assay. The results of a typical experiment are summarised in Table 1. The specificity of the inhibitor for the nuclear protein kinases ruled out the possibility that inhibition was due to some nonspecific interference with the assay, such as ATPase or protease activities in the extract, because such activities would also give an apparent inhibition of the phosphotransferase reaction catalysed by the cytoplasmic protein kinases. It did not eliminate the possibility that the inhibitor was a phosphoprotein phosphatase, as we have previously shown that the nuclear phosphoprotein phosphatases have a pronounced substrate preference for nuclear phosphoproteins over phosphoprotamine[13]. However, this possibility could also be discounted, as when nuclear phosphoproteins, prepared from livers of rats injected with ^{32}P 90 min before death, were incubated with the inhibitor for 30 min at 30 °C, there was no loss of phosphate from TCA-precipitable material.

We have previously shown that the nuclear protein kinases, in contrast to the cytoplasmic enzymes, are stimulated by polyamines, but not by cyclic AMP[6,7], and are not inhibited by the

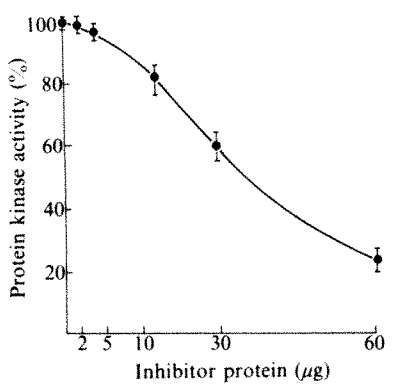

Fig. 2 Nuclear protein kinase (0.1 unit) was incubated with various amounts of inhibitor protein purified through the DEAE-cellulose step as described in the text. The inverse proportionality between remaining enzyme activity and amounts of inhibitor added is that predicted by the Michaelis–Menten relation for the reversible interaction between an enzyme and its inhibitor.

Table 1 Effect of the inhibitor protein on nuclear and cytoplasmic protein kinases

Protein kinase	Substrate	Other additions	nmol ^{32}P incorporated per min per mg	% Inhibition
Nuclear				
Phosphocellulose				
Peak 3	Casein	None	0.49	
	Casein	Inhibitor	0.34	31
Peak 4	Casein	None	1.32	
	Casein	Inhibitor	0.83	37
Peak 5	Casein	None	0.25	
	Casein	Inhibitor	0.15	40
Cytoplasmic				
	Casein	None	0.46	
	Casein	Inhibitor	0.46	0
	Casein	+cyclic AMP (5×10^{-6} M)	0.48	
	Casein	+cyclic AMP+ inhibitor	0.49	0
	Histone	None	0.76	
	Histone	Inhibitor	0.74	2.5
	Histone	+cyclic AMP (5×10^{-6} M)	3.05	
	Histone	+cyclic AMP+ inhibitor	2.97	2.5

Nuclear protein kinases were prepared and freed of endogenous substrate[12] and fractionated on phosphocellulose as previously described[6]. Cytoplasmic protein kinase was a 100,000g rat liver supernatant. Casein and histones were present at 200 μg in the 0.2-ml standard assay[12].

* Inhibitor protein (30 μg) was purified by the DEAE-cellulose step as described in the text.

cytoplasmic heat-stable inhibitor protein[6] that specifically inhibits cyclic AMP-dependent protein kinases by interacting with their catalytic subunit[14]. Here we report the presence in rat liver nuclei of a heat-sensitive inhibitor of 150,000 molecular weight that behaves as an acidic protein and is specific for the nuclear enzymes. Taken together, these findings suggest that the nuclear protein kinases are subject to controls that are specific and distinct from those regulating the cytoplasmic enzymes which primarily mediate the effects of cyclic AMP.

We believe this inhibitor to represent the only negative modulator of nuclear protein kinase activity described to date. It is suggested that the inhibitor may play an important part in the regulation of nuclear protein phosphorylation. Moreover, it can be expected to be a valuable tool in assessing the possible role of nuclear protein phosphorylation in nuclear RNA metabolism and gene activation.

A chiasma–hormonal hypothesis relating Down's syndrome and maternal age

THE incidence of the human congenital abnormality known as Down's syndrome (or mongolism) has been observed to increase with maternal age[1]. The trend of sharply increased incidence beyond the age of 30 has been well documented[2], and various hypotheses have been formulated to explain it. These include cumulative ovum or uterine dysfunction (radiation[3], chemicals[4], disease[5]), acute effects of radiation and chemicals, hormonal effects[6], the 'production line' hypothesis[7,8] and changes in sexual behaviour[9]. We describe here our hypothesis that there is an interaction between the hormonally governed rate of meiosis and the timing of chiasma terminalisation. We propose that changing hormone levels during the menstrual cycle not only trigger resumption of meiosis in the ovum[10], but also control the rate of meiosis through the availability of a limiting substance[11]. As hormone levels and the length of the cycle change with advancing age of the mother, meiosis slows down, and chiasma frequencies decline[7,12]. Meiotic chromosome bivalents are held together by their chiasmata against strong mutual repulsion during late dictyotene and diakinesis[13], making smaller bivalents with fewer chiasmata, such as 21, the most vulnerable to premature separation during terminalisation[14,15]; premature separation can lead to trisomy 21, by far the most frequent cytological manifestation of Down's syndrome[16].

17β-Oestradiol may stimulate the production of luteinising hormone (LH) receptors in the follicle either directly through transcription[17,18] or indirectly by increasing the number of granulosa cells surrounding the ovum[19]. Thus, LH receptors could accumulate during the menstrual cycle as an integral function of oestradiol concentration. At corresponding points in the cycle, LH concentration varies little[20], but oestradiol decreases with age[20,21] (see Fig. 1 legend).

After meiosis resumes in the ovum at the LH surge, the rate of meiosis is assumed to be limited by a substance released in response to LH[19] (for example, cyclic AMP[10] or Ca^{2+} (ref. 22)). As LH concentration remains high during this part of the cycle, the intensity of the LH stimulus may be limited by the number of LH receptors rather than by LH concentration[19]. In this simplest case, the accumulation rate of the limiting substance is directly proportional to the number of receptors. By ignoring allosteric or other complexities of the rate-limiting reaction, the rate of meiosis can be expressed as the Michaelis–Menten function in equation (1) (Fig. 1 legend).

Estimating the minimal interval from LH peak to ovulation to be 12 h (ref. 23), we add 24 h for the duration of the LH surge[24] to obtain the interval from resumption of meiosis to ovulation (end of meiotic division I) in women at age 20; we can then use equation (1) to predict this interval for other ages. Bivalents become attached to spindle fibres roughly 18 h after the resumption of meiosis in women at age 20 (ref. 25), but equation (1) implies that this pre-alignment interval lengthens for older women, with an increasing chance of losing chiasmata before proper alignment. We assume that the starting times of terminalisation can be represented by a normal distribution independent of age. As a first approximation, let the frequency of premature univalents be given by the frequency of bivalents whose chiasmata terminalise before spindle attachment. Then the frequency of prematurely terminalised chiasmata is expressed by equation (2) (Fig. 1 legend). Note that if terminalisation of individual bivalents is rapid relative to the time scale of meiosis, as seems likely, the exact number and positions of chiasmata become unimportant.

Assuming that unaligned univalents 21 successfully attach to the spindle but segregate independently at anaphase I (ref. 8), allowing for a partial fetal viability (we use 0.235 (ref. 26)) and multiplying by 1,000, we obtain the incidence per 1,000 births of trisomy 21 as a function of maternal age in equation (3) (Fig. 1

0028-0836/79/310417—03$01.00

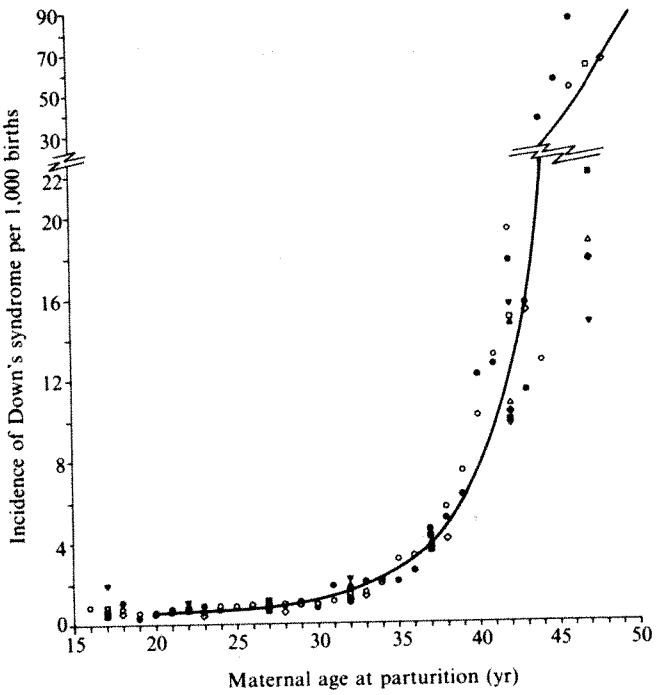

Fig. 1 Incidence of Down's syndrome per 1,000 births versus maternal age at parturition. Data from eight of the studies cited are for 5-yr age intervals; data from the last two studies are for 1-yr intervals. The curve illustrates one reasonable fit to these data of the model developed here, for which the two fitted parameters are $\sigma = 7.09$ and $K_m/k_1k_0 = 7{,}000\ h^2$. This result assumes a reverse sigmoid decline beyond age 20 in peak oestradiol concentration ($c(a) = 1{,}176/(a^2 - 40a + 1{,}576)$) and a linear peak shift ($p(a) = 603 - 8.53a$, where p is time in hours to the oestradiol peak from the beginning of the cycle) with age a in years. The general forms and parameters of these two functions are suggested by data in Sherman and Korenman[20]. Key equations from the derivation outlined in the text are:

$$\rho(a,t) = \frac{\rho_{max}M(a,t)}{K_m + M(a,t)} = \frac{\rho_{max}c(a)\int_0^t\int_{t_0}^s E(u)\,du\,ds}{K_m/k_1k_0 + c(a)\int_0^t\int_{t_0}^s E(u)\,du\,ds}, \quad (1)$$

where ρ is the rate of meiosis at time t during the cycle of a woman of age a, h^{-1}; ρ_{max} is the maximal rate of meiosis ('limiting' substrate present in excess), h^{-1}; M is the concentration of the rate-limiting metabolite, $ng\,l^{-1}$; a is maternal age, yr; t is time during the menstrual cycle, h; K_m is the Michaelis constant, $ng\,l^{-1}$; c expresses the decline in oestradiol concentration with age a, normalised such that $c(20) = 1$; t_0 is an initialisation time, taken here to be the beginning of the cycle; E is the oestradiol concentration during the cycle, $ng\,l^{-1}$; k_1 is the rate constant for metabolite accumulation, h^{-1}; and k_0 is the coefficient for the accumulation of LH receptors, $ng\,l^{-1}h^{-1}$.

$$F(fi) = \int_0^{fi} P(r)\phi(r)\,dr$$

where

$$P(r) = \begin{cases} 0 & \text{if } fi \leq r \\ \alpha(fi - r) & \text{if } fi > r \geq fi - 1/\alpha \\ 1 & \text{if } fi - 1/\alpha > r \end{cases} \quad (2)$$

and

$$\phi(r) = \exp[-(r-\tau)^2/2\sigma^2]/2\pi\sigma$$

and where F is the frequency of unaligned univalents; f is the pre-alignment fraction of the interval between resumption of meiosis and ovulation; i is the duration of this entire interval, h; $P(r)$ is the probability of terminalisation by time r(h) after the resumption of meiosis; α is the terminalisation rate, h^{-1}; ϕ is the frequency distribution of first terminalisation times, of which τ is the mean and σ is the standard deviation, h.

$$I(a) = 1{,}000vF(fi(a))/(2+v) \quad (3)$$

where I is the incidence per 1,000 births of trisomy 21, and v is the fraction of 21-trisomic zygotes surviving to birth divided by the fraction of all other zygotes surviving to birth. ◆, Ref. 33; △, ref. 34; ■, ref. 35; ▼, ref. 36; □, ref. 37; ▲, ref. 38; ▽, ref. 39; ◇, ref. 40; ○, ref. 41; ●, ref. 42 (corrected for sparcity of data).

legend). The curve in Fig. 1 illustrates a reasonable fit to the data of equation (3) found by appropriately adjusting the two parameters σ and K_m/k_1k_0.

The curve in Fig. 1 accelerates sharply in response to both the $i(a)$ function and the leading tail of the cumulative normal function $\int \phi(t)\,dt$. By the analysis presented here, neither the hormonal (i) nor the chiasma (ϕ) effects alone can bend the incidence curve sharply enough to fit the data, but taken together, as in equation (2), they can provide sufficient acceleration.

The chiasma–hormonal hypothesis proposed here yields some testable (but as yet untested) predictions: (1) The interval during the cycle between the LH peak and ovulation increases with maternal age (see refs 27, 28). (2) The incidence of trisomies will respond to experimental manipulation of intrafollicular hormone levels (see refs 29, 30). (3) Chiasma frequencies in the bivalents 21 of human females decrease with age during post-arrest dictyotene and diakinesis (see refs 7, 11 in mice).

Our hypothesis clearly emphasises the need for further experimental studies that link hormonal signals with cytological events, and for further information on the dynamics and significance of chiasmata before and during segregation. Thorough documentation of intrafollicular hormone levels during a cycle would be particularly useful, avoiding the necessity for extrapolating (as here) from systemic levels to follicular levels.

We have not formally considered the incidence trend below a maternal age of 20 yr in the model presented here. We suspect that the typically higher incidence of Down's syndrome in children of mothers younger than 20 (see Fig. 1) results from a higher variability of hormone levels among cycles as the complex neuro-endocrine feedback controls are still being established[31]; none of the other mechanisms assumed to operate in meiotic division I could so easily account for this higher incidence for very young mothers. The behavioural mechanism is not necessarily inconsistent with this pattern below age 20, but the finding that the majority of maternal meiotic segregation errors occur during division I (ref. 32) seems to preclude a significant behavioural effect.

Many other specific models, perhaps focusing on other hormones (follicle-stimulating hormone, progesterone) or other hormone interactions, could probably fit the data of Fig. 1 equally well. The parsimonious LH–oestradiol interpretation is primarily intended to illustrate the essential implications of the general chiasma–hormonal mechanism.

We thank Drs Ernest Hook, Montrose Moses, Ian Shine, Jesse Sisken, Emery Wilson and M. B. Nikitovitch-Winer for valuable comments and suggestions during this study.

Specific DNA methylation sites in the vicinity of the chicken β-globin genes

METHYLATION of cytosine is the only post-synthetic modification so far detected in the DNA of higher eukaryotes and thus has been made the basis of several proposed mechanisms of gene activity and cellular differentiation[1–3]. All evidence indicates, however, that the overall content of 5-methylcytosine in DNA does not vary significantly between different tissues of the same organism and does not change throughout at least some steps of differentiation[4–6]. As 5-methylcytosine occurs predominantly in the dinucleotide sequence CpG (ref. 7) and as a number of bacterial restriction endonucleases can distinguish whether this sequence is methylated or unmethylated, it is now possible to investigate DNA methylation patterns in the vicinity of single genes[8]. In this report, we use this technique to provide a correlation between DNA methylation and the activity of the chicken β-globin genes.

The restriction endonuclease *Hpa*II cleaves the DNA sequence CCGG (ref. 9) but does not cleave the methylated sequence C(MeC)GG (ref. 10). A second restriction endonuclease, *Msp*I, is able to cleave this same DNA sequence whether it is methylated or not[11]. Thus DNA from any cell or tissue type can be digested with either *Hpa*II or *Msp*I, the cleaved DNA electrophoresed on an agarose gel, transferred to a nitrocellulose filter[12] and hybridised to a gene-specific probe. Any bands seen in the autoradiogram which differ between the two enzyme digests can reasonably be ascribed to differences in methylation of CCGG sites in the vicinity of the specific gene. This kind of experiment, used here to examine the chicken β-globin genes, has recently been used to investigate a single methylation site in the large intervening sequence of the adult rabbit β-globin gene[13].

Figure 1 shows the autoradiogram from an experiment with chicken DNA, using the plasmid pHb1001 as a ^{32}P-labelled hybridisation probe (pHb1001 is a cDNA clone of the adult chicken β-globin gene[14], provided by Dr W. Salser). Figure 1*a* represents the *Hpa*II digest of adult chicken erythrocyte DNA and shows bands at 4.2 and 1.3 kilobase pairs. These fragment sizes should correspond to distances between unmethylated CCGG sites in the DNA regions containing β-globin genes. Figure 1*b* represents the *Msp*I digest of the same adult erythrocyte DNA and shows bands at 2.0 and 1.3 kilobases, as well as a faint but reproducible band at 0.4 kilobases. These fragment sizes should correspond to distances between both methylated and unmethylated CCGG sites in the β-globin gene DNA. The 1.3-kilobase fragment is of similar intensity in both digests.

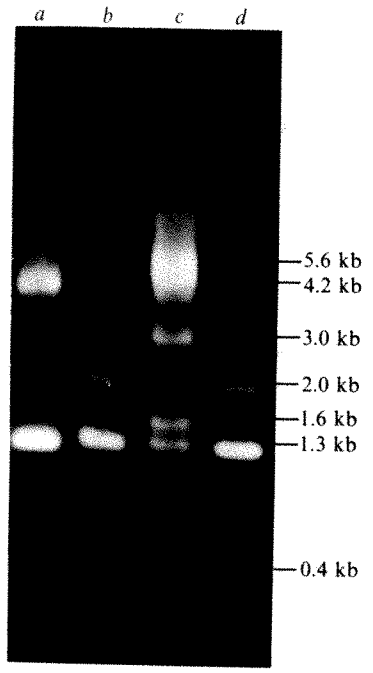

Fig. 1 DNA was isolated from chicken tissues by extensive digestion with proteinase K (Merck) in the presence of 0.2% SDS with or without previous isolation of nuclei. This was followed by at least three extractions with an equal volume of phenol–chloroform–isoamyl alcohol (25:24:1), three extractions with two volumes of chloroform–isoamyl–alcohol (24:1), and three ethanol precipitations. In a typical digestion protocol, 200 units of restriction enzyme were added to 100 μg DNA in a final buffer of 6 mM KCl, 10 mM Tris-HCl (*p*H 7.5), 10 mM $MgCl_2$, 1 mM dithiothreitol and 100 μg ml^{-1} autoclaved gelatin. (The enzyme *Msp*I was obtained from New England Biolabs. The enzyme *Hpa*II was obtained from either New England Biolabs, Bethesda Research Laboratories, or Boehringer–Mannheim; all gave identical results. It was verified that, in the digestion conditions used, both *Hpa*II and *Msp*I gave identical cleavage patterns with the plasmid pBR322.) The reaction was incubated at 37 °C for 2 h, a further 200 units of enzyme were added and incubation was continued for an additional 2 h at 37 °C. Identical results were obtained if this second incubation was continued for 10–15 h. The completion of digestion was monitored by adding a small amount of bacteriophage λ DNA to an aliquot of either the first or the second incubation mixture and verifying by electrophoresis that the required cleavage products were present. After digestion, the DNA was repurified by repeating the proteinase K digestion and organic extraction steps described above, and 25–50 μg electrophoresed on each slot of a 1% agarose slab, 6 mm thick, for 2 h at 200 V. DNA was then transferred to Schleicher and Schuell nitrocellulose filters by the method of Southern[12], the filters hybridised to ^{32}P-labelled nick-translated pHb1001 for 24 h at 70 °C in 6 × SSC, washed in 3 × SSC, and finally washed for 30 min in 0.1 × SSC. Filters were exposed to Kodak XR5 X-ray film for 24–96 h at −80 °C, using two Dupont Cronex intensifying screens. A typical autoradiogram is shown above and described in more detail in the text. *a*, Adult erythrocyte DNA digested with *Hpa*II; *b*, adult erythrocyte DNA digested with *Msp*I; *c*, oviduct DNA digested with *Hpa*II; *d*, oviduct DNA digested with *Msp*I. Band sizes were calibrated relative to a *Hin*dIII digest of λ and a *Hae*III digest of ΦX174 DNA, run in an adjacent gel slot, and are probably accurate to 5%. Identical *Hpa*II digestion patterns were obtained with DNA from erythrocytes or reticulocytes isolated from several individual adult roosters and chickens, of both White Rock and Leghorn breeds. *Hpa*II digestion of a mixture of erythrocyte and oviduct DNA yielded a pattern which was the expected sum of the patterns of slots *a* and *c* above. A digest of the same DNA with a mixture of *Hpa*II and *Msp*I yielded only the *Msp*I digestion pattern. The *Msp*I digestion pattern of all DNA samples investigated was identical to that in slots *b* and *d* above. Digestion with several restriction endonucleases which do not have CG as part of their recognition site gave the same digestion patterns in different tissues (see also ref. 16).

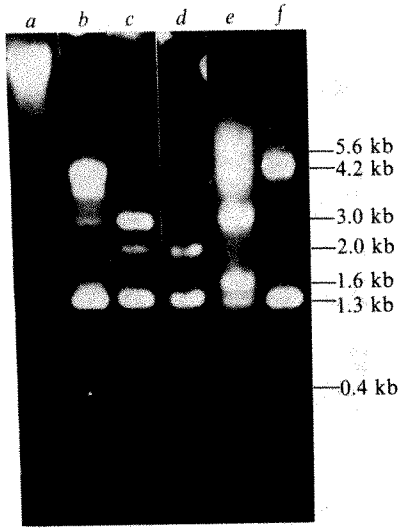

Fig. 2 *a–d*, Partial digestion of adult erythrocyte DNA with the restriction endonuclease *Msp*I; *a*, no enzyme control; *b*, 2 units; *c*, 12 units; *d*, 100 units of enzyme. All incubations were for 2 h at 37 °C with 50 μg DNA and using the buffer conditions described in Fig. 1. *e*, Complete *Hpa*II digest of erythrocyte DNA from 5-d-old embryos. For comparison, slot *f* is a complete *Hpa*II digest of adult erythrocyte DNA.

However, the *Hpa*II digest (*a*) lacks both the 0.4 and 2.0 kilobase fragments of the *Msp*I digest as well as any other bands which could correspond to a combination of the *Msp*I bands. This suggests that the CCGG sites at the ends of the 1.3-kilobase fragment are completely (>90%) unmethylated in adult chicken erythrocyte DNA and furthermore, that at least two other specific sites are completely methylated. DNA isolated from the circulating reticulocytes of phenylhydrazine-induced anaemic adult chickens gives digestion patterns which are essentially identical to those of adult erythrocyte DNA (data not shown). These results are in contrast to those for the rabbit β-globin gene[13], where in both marrow and spleen cells of anaemic rabbits, only partial methylation of a site in the large intervening sequence was observed; this difference could be due to the different positions of the cleavage sites within the gene sequence or, as the authors have pointed out[13], due to a heterogeneous cell population.

Figure 1*c* shows the *Hpa*II digest of oviduct DNA. The observed band pattern is not only different from the *Msp*I digest of the same DNA (Fig. 1*d*) but also different from the *Hpa*II digest of erythrocyte DNA (Fig. 1*a*). There are now prominent bands at 4.2, 3.0, 1.6 and 1.3 kilobases (as well as several weaker but poorly resolved bands at higher molecular weight). As Fig. 2*b* and *c* show, all these bands appear as partial digestion products of adult erythrocyte DNA by the enzyme *Msp*I. This suggests that, in the oviduct, CCGG sequences in the vicinity of the β-globin genes are only partially methylated. Nevertheless, the absence of the 2.0-kilobase band suggests that at least one such sequence is completely methylated. As shown in Fig. 2*e*, DNA isolated from the circulating red blood cells of 5-d-old embryos (in which the adult β-globin gene is not being expressed[14,15]) or from adult brain (data not shown) gives digestion patterns essentially identical to that of oviduct DNA.

The legend to Fig. 1 summarises control experiments which show that the above results are not due to partial digestions, DNA isolation methods, enzyme inhibitors, DNA sequence rearrangements or individual differences between chickens. Figure 2*a* also provides an important control, showing that undigested DNA is still transferred to the nitrocellulose filter for hybridisation; thus, any high molecular weight bands would have been detected.

One current difficulty in assigning the observed bands to their positions within the gene sequence arises from the fact that the adult chicken β-globin gene in pHb1001 shares considerable sequence homology with at least one of the embryonic β-globin genes[16], and both sequences can show up on the filter hybridisations. However, our preliminary results using a genomic clone (G.D.G., W. I. Wood and G. Felsenfeld, unpublished) indicate that the prominent 1.3-kilobase fragment shown in Figs 1 and 2 is derived from the adult β-globin gene sequence; moreover one end of this fragment lies within about 30 bases of the 5'-end of the coding sequence[14].

It is undoubtedly premature to relate DNA methylation patterns to a specific biological activity. It does seem clear, however, that the observed tissue differences do not solely reflect different rates of cell division, as both adult and embryonic red cells have ceased division and yet their DNA shows different methylation patterns. Moreover, brain, a non-proliferating tissue, shows the same pattern as the proliferating oviduct. On the other hand, at least some correlation can be made between these methylation patterns and globin gene activity. In cells which are expressing or have expressed the adult β-globin gene (adult reticulocytes and erythrocytes) the CCGG sites near the ends of the gene sequence (that is at the ends of the 1.3-kilobase fragment) seem to be completely unmethylated. In cells which are not expressing this gene (oviduct, brain and embryonic red blood cells) these sites can be at least partially methylated. The determination of how these specific methylation events occur during cellular differentiation must await a more detailed description of their exact positions in the gene sequence. Nevertheless, we believe these results to be the first correlation between site-specific DNA methylation and eukaryotic gene expression.

We thank Dr Gary Felsenfeld for advice and encouragement, and Dr W. Salser for providing an unpublished characterisation of the plasmid pHb1001.

Long regions of single-stranded DNA in human cells

WHEN DNA is isolated from actively growing animal cells by a variety of standard procedures, 1–2% of the total DNA is recovered in single-stranded form[1–5]. Pulse labelling experiments have established that the large majority of the single-stranded DNA is not newly synthesised[3,5]. However, a minor part of this DNA fraction consists of short fragments of newly replicated DNA released by branch migration during isolation[6,7]. Studies with synchronised human cells have shown that single-stranded DNA is mainly found during the period of DNA synthesis[3,4]. In agreement with this, a specific antiserum against denatured DNA used for immunofluorescence has revealed the presence of single-stranded DNA in nuclei of a human lymphoid

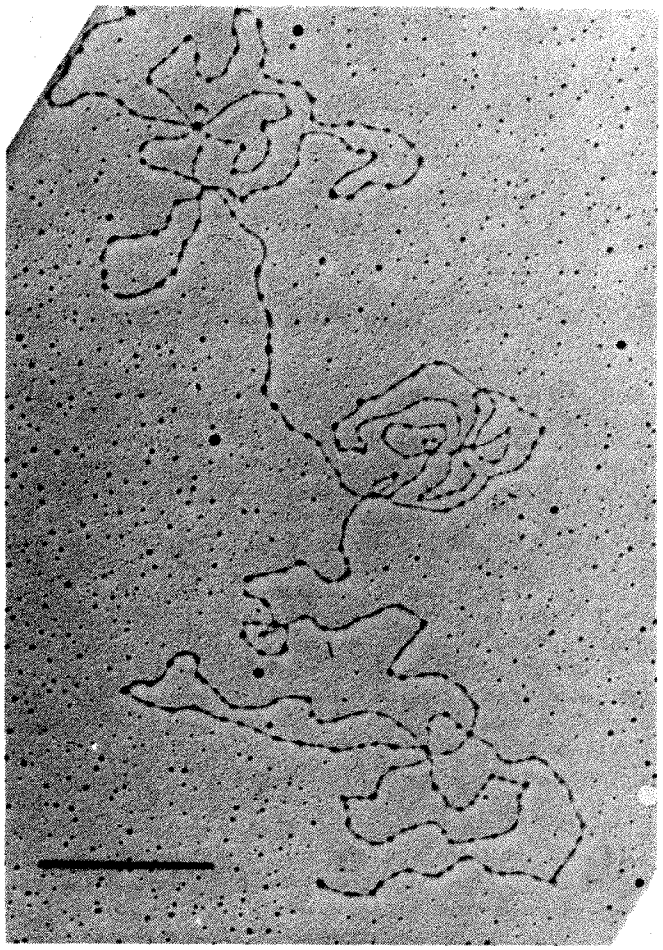

Fig. 1 Electron micrograph of a long single-stranded DNA molecule isolated from the human lymphoid cell line Molt-4. The DNA was spread in the presence of 30% formamide by the technique of Davis *et al.*[13]. In comparison with an internal reference, phage ΦX174 DNA, this molecule has a molecular weight of 40×10^6. Scale bar, 1 μm.

cell line during the S phase but not during the G1 phase[8]. DNA hybridisation measurements indicate that the single-stranded sequences belong to the non-repetitious fraction of the DNA and that at least part of this material contains sequences transcribed *in vivo*[2]. We have developed gentle isolation methods to purify large, covalently closed circular DNA molecules from human lymphocytes transformed by the Epstein–Barr virus (EBV)[9]. These methods do not cause the conversion of linear double-stranded DNA to single-stranded forms[5,9]. We have repeatedly observed by electron microscopy long single-stranded stretches of host DNA that initially co-purified with the guanine–cytosine-rich viral episomal DNA. This single-stranded DNA accounted for about 1% of the total cellular DNA in several different lymphoid cell lines derived from Burkitt lymphoma patients or from healthy donors, while the EBV DNA sequences in the same lines only constituted 0.02–0.1% of the total DNA. Clearly, the single-stranded sequences were mainly or exclusively of host origin. Long regions of single-stranded DNA, indistinguishable from those present in EBV-transformed cells, were also found in similar amounts in two EBV-negative human lymphoid cell lines of different origin, BJAB[10] and Molt-4 (ref. 11). This report looks at these single-stranded DNA molecules, which are considerably larger than any previously isolated from animal cells.

Molt-4 cells were grown in stationary suspension culture at 37 °C in RPMI-1640 medium (GIBCO) supplemented with 15% fetal bovine serum and antibiotics. High molecular weight DNA was prepared by treatment of washed cells with Sarkosyl and Pronase, followed by CsCl density gradient centrifugation[9]. Fractions of higher density (1.715–1.735 g cm^{-3}) than the main band DNA (1.700 g cm^{-3}) were recovered with the aid of a closed system collection device to minimise shearing forces[9]. This material, which contained about 5% of the total cellular DNA, was further fractionated by neutral glycerol gradient centrifugation in the presence of 1 M NaCl. The conditions were as described previously[9], except that the time of centrifugation was reduced to 2 h, polyallomer tubes were used, and the size marker (phage T4 ^{14}C-DNA) was run in a separate tube. The purpose of the latter fractionation step was to purify further large single-stranded DNA molecules, which sediment faster than double-stranded molecules of similar size[12]. Different fractions of a glycerol gradient were dialysed free from glycerol, and circular single-stranded DNA from bacteriophage ΦX174 was added as an internal reference. The fractions were then examined by electron microscopy, using the formamide modification of the Kleinschmidt technique[13].

The fastest sedimenting DNA detected had a sedimentation coefficient of 150–160S. This DNA seemed to be entirely single stranded, as judged by electron microscopy (Fig. 1). Using contour length measurements the DNA was estimated to have a molecular weight of 40×10^6. Note that a single-stranded DNA molecule of this size would be expected to have a sedimentation coefficient of 156S in neutral 1 M NaCl (ref. 12). Furthermore, these long DNA molecules as well as the ΦX174 DNA were no longer detected after treatment with pancreatic DNase or single-strand-specific S_1 nuclease, while they were resistant to pancreatic RNase.

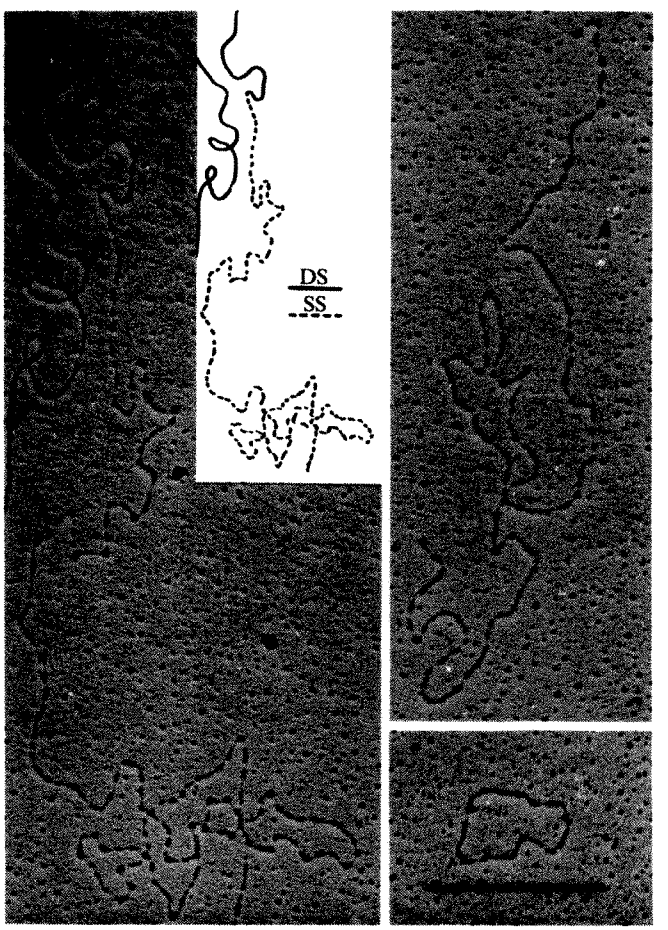

Fig. 2 Single-stranded DNA from Molt-4 cells. Left, a molecule comprising both double-stranded (DS) and single-stranded (SS) DNA. The length of the single-stranded region is 17×10^6 MW. Upper right, a well extended single-stranded DNA molecule of 14×10^6 MW. Lower right, single-stranded circular DNA from bacteriophage ΦX174 of $1{\cdot}8 \times 10^6$ MW. Scale bar, 1 μm for all pictures.

Table 1 Single-stranded DNA from cells in different growth phases

	Sample A (early S phase)	Sample B (mid S phase)	Sample C (G2 phase)
Number of double-stranded DNA molecules per field square	6.1	5.4	7.4
Number of double-stranded molecules measured	43	38	52
Average length of double-stranded DNA (μm)	38.5	43.2	32.1
Number of single-stranded DNA molecules per field square	1.2	0.9	0.6
Number of single-stranded molecules measured	29	23	16
Average length of single-stranded DNA (μm)	18.0	23.5	11.3
Proportion of DNA in single-stranded form (%)	9.2	9.1	2.9

DNA preparations were spread in the presence of 30% formamide[13]. Bacteriophage PM2 DNA in open circular form (MW 6.4×10^6) was used as size reference. A length correction (based on parallel measurements of double-stranded and single-stranded ΦX174 DNA) was performed to correct for differences in spreading between double-stranded and single-stranded DNA.

Most of the high molecular weight DNA investigated here sedimented as a broad peak around 70S on glycerol gradients. In the region of a gradient containing molecules sedimenting at >50S, which presumably would be free from any newly replicated DNA fragments of low molecular weight, about 20% of the total material was found in single-stranded form (Fig. 2). The size distribution of the single-stranded DNA recovered is shown in Fig. 3. It seems that the single-stranded DNA is not of unique size, and that a considerable part of this material is as much as $20–40\times10^6$ MW. However, the long DNA chains are very shear sensitive, and could be derived from even larger single-stranded or partly single-stranded molecules, fragmented during isolation.

To investigate the alkali stability of the material, a fast-sedimenting DNA fraction (100–120S) containing a relatively large amount of single-stranded DNA was brought to *p*H 12.7 by the addition of NaOH, left at 20 °C for 15 min, neutralised, and immediately spread for electron microscopy. A control experiment with bacteriophage λ DNA showed that double-stranded DNA was completely converted to intact single strands in these conditions. An aliquot of a 100–120S DNA fraction isolated from Molt-4 cells contained 26 DNA molecules, of which 22 were single-stranded molecules between 11 and 35 μm long, and 4 were double-stranded molecules. A similar aliquot from the alkali-denatured material contained 7–42-μm long single-stranded DNA molecules. There was no detectable decrease in the average length (about 20 μm) of the chains after exposure to alkali. These data show that the material shown in Figs 1–3 consists of long single-stranded DNA molecules rather than hydrogen-bonded aggregates of short chains.

As it has been reported that single-stranded DNA is primarily found in growing cells in S phase[3,4,8], it was of interest to see if the much longer single-stranded regions detected here were also mostly present during active DNA synthesis. Human lymphoid cells were therefore synchronised by the double thymidine blocking technique[14]. This procedure is of varying effectiveness with different lymphoid lines, but Raji cells respond well[14] and were used for this experiment. DNA was prepared from cells mainly in early S, middle S, and G2 phase (Fig. 4), and fractionated by CsCl gradient centrifugation. The high-density material was recovered and investigated by electron microscopy. The DNA preparations from S phase cells contained about three times larger amounts of single-stranded material than the preparation from cells mainly in G2 phase (Table 1). These data

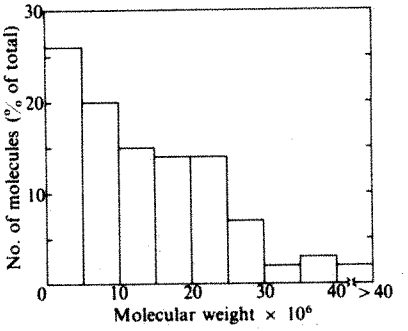

Fig. 3 Size distribution of long single-stranded DNA regions. Molt-4 DNA was fractionated by neutral CsCl and neutral glycerol density gradient centrifugations, and the material sedimenting at >50S was investigated. Both entire single-stranded molecules and single-stranded regions in partly double-stranded molecules were included, and 100 molecules were measured.

agree with previous findings[3,4,8] that single-stranded DNA is primarily (or exclusively) found in S phase cells.

The subcellular distribution of the single-stranded DNA was investigated by preparation of Raji cell nuclei by Nonidet 40 treatment as described previously[15]. High molecular weight DNA preparations were made in parallel from both whole cells and isolated cell nuclei, and after CsCl density gradient centrifugation, the DNA density fractions 1.720–1.740 g cm^{-3} was examined by electron microscopy. In both these preparations 10–15% of the high molecular weight material was single-stranded DNA. Thus, we conclude that most or all of the long regions of single-stranded DNA described here is of nuclear origin.

When Molt-4 cells were pulse-labelled with 10 μCi ^{3}H-thymidine per ml 30 min before collecting the cells for preparation of DNA, the total DNA had a specific radioactivity of 4,000 c.p.m. per μg. After enrichment of large single-stranded DNA molecules by CsCl and glycerol gradient centrifugation as above, a fast-sedimenting fraction representing about 0.3% of the total DNA and containing 50% single-stranded material was obtained. This DNA had a specific activity of about 3,000 c.p.m. per μg. Although the estimate of the DNA concentration is only semi-quantitative, these data strongly indicate that the large

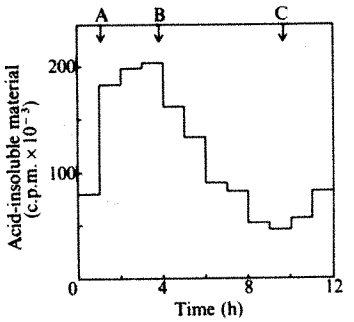

Fig. 4 DNA synthesis in synchronised lymphoid cells. Cells (60×10^6) of the Raji line were propagated in stationary suspension culture and synchronised by the double thymidine blocking technique as described by Hampar *et al.*[14]. After release from the block, DNA synthesis was monitored by 1-h pulse-labelling of aliquots of 5×10^5 cells with 5 μCi ^{3}H-thymidine. At the three time points indicated by arrows, 15×10^6 cells were collected and used for the preparation of high molecular weight DNA. Each DNA solution was fractionated by neutral CsCl density gradient centrifugation[9]. Fractions of density 1.720–1.740 g cm^{-3}, which represented about 2% of the DNA in the gradient, were pooled, dialysed and investigated by electron microscopy (see Table 1).

single-stranded DNA regions do not represent newly synthesised DNA, again confirming previous results[3,5].

Methods used previously[1-5] to isolate single-stranded DNA from mammalian cells yield larger amounts of material suitable for further characterisation. However, the approach used here reveals the unexpected length of much of this single-stranded DNA. It seems unlikely that such long regions could be due to DNA destabilised by transcription or DNA repair, or to DNA sequences serving as regulatory signals. Note that during replication of adenovirus DNA in cell nuclei, the replication process occurs in a completely asymmetric manner with the generation of single strands of entire parental virus DNA as replication intermediates[16,17]. Single-stranded DNA of the size range described here can thus exist in cell nuclei without being degraded. Also, mitochondrial DNA is synthesised in an asymmetric manner with the temporary generation of single-stranded regions of parental DNA[18].

Recently, it has been found that both adenovirus DNA and mitochondrial DNA are replicated by DNA polymerase γ (refs 19, 20), whereas most of the nuclear DNA is replicated by DNA polymerase α in a symmetrical, bi-directional way[21,22]. Both these polymerases are present in the nuclei of uninfected cells and are thought to act in DNA replication, as they are present in increased amounts in S phase cells[23]. It seems that two fundamentally different modes of DNA replication may occur in human cells, symmetric synthesis catalysed by DNA polymerase α and asymmetric synthesis catalysed by DNA polymerase γ (ref. 19). The long single-stranded DNA regions visualised here may then represent displaced strands of parental DNA in asymmetric DNA synthesis.

Codon–anticodon interaction at the ribosomal peptidyl-site

VARIOUS models have been proposed to explain the interaction between an aminoacyl-tRNA molecule and the ribosomal A and P sites during one elongation cycle of protein biosynthesis[1-7]. In general all these models agree as to the existence of at least two tRNA binding sites on the 50S subunit, the A and P sites. These models, however, do not agree on the important question of whether mRNA–tRNA (codon–anticodon) recognition occurs exclusively in the A site or in both A and P sites. Previous experimental evidence adduced in favour of either hypothesis has usually been based on analysis of the effects of various antibiotics on the partial reactions of protein synthesis. However, molecular mechanisms of action of such antibiotics are still poorly understood, and definite conclusions as to which type of model is correct cannot be based solely on such data. Here we show that factor-mediated binding of aminoacyl–tRNA (aa–tRNA) to the ribosomal A site is dependent on the presence of both an mRNA codon in the P site and of a tRNA which recognises that codon. Thus binding of a ternary complex EF-Tu · aa-tRNA · GTP to the ribosomal A site occurs only if the P site is occupied by a tRNA for which codon–anticodon interaction is maintained (for a preliminary report see ref. 8).

Initially we studied the binding of Phe–tRNA to ribosomes in the presence of 8 mM Mg^{2+} using oligouridylate templates with a chain length of between 3 and 10: the chain length dependence was found to be different in the presence and absence of EF-Tu (Fig. 1). Considerable nonenzymatic Phe–tRNA binding to 70S ribosomes was observed (even at this low Mg^{2+} concentration) with each of the eight oligouridylates investigated. Even with the triplet UUU, 3 pmol of Phe–tRNA were bound to 100 pmol 70S ribosomes, and only a small increase was observed with the longer oligouridylates (Fig. 1). In striking contrast to nonenzymatic binding, no EF-Tu mediated binding of Phe–tRNA was observed unless the chain length of the oligouridylate was equal to or longer than 6 (Fig. 1).

The requirement for $(U)_6$ for enzymatic binding of Phe–tRNA suggests that two tRNA molecules form a codon-dependent complex with the ribosome. Aminoacylated Phe–$tRNA^{Phe}$, exclusively present as preformed ternary complex, bound into

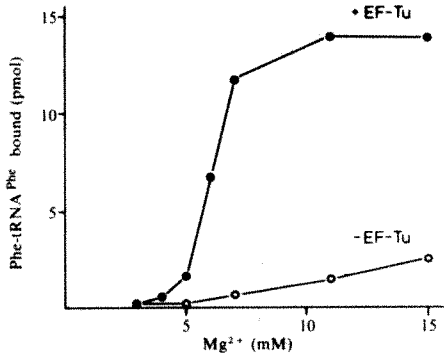

Fig. 1 Enzymatic (●) and nonenzymatic (○) binding of Phe-tRNA to 70S ribosomes in the presence of oligonucleotide $(U)_3$ to $(U)_{10}$. The binding of Phe-tRNA to 70S ribosomal tight couples[9] was assayed as follows: 75 μl of a mixture containing 20 mM Tris–HCl (*p*H 7.5), 50 mM NH_4Cl, 10 mM 2-mercaptoethanol, 8 mM magnesium acetate, 100 pmol 70S ribosomes and 25 nmol oligouridylate[10] was preincubated for 5 min at 37 °C and cooled on ice. For nonenzymatic Phe–tRNA binding the sample was then supplemented with 25 μl of a mixture containing the same salt concentrations as above, together with 100 pmol bulk [^{3}H]Phe–tRNA (2 Ci mmol^{-1}, charging degree 2%). When enzymatic Phe–tRNA binding was to be measured, 300 pmol EF-Tu[11] and 0.2 μmol GTP were included. The mixtures were incubated for 10 min at 37 °C. Ribosomal binding of Phe–tRNA was measured by the Millipore filter technique[12].

Table 1 Binding of Phe-tRNA to 30S ribosomal subunits with oligonucleotide $(U)_3$ to $(U)_7$ in the presence and absence of EF-Tu

Oligonucleotide	Phe-tRNA^{Phe} bound (pmol)	
	EF-Tu absent	EF-Tu present
$(U)_3$	4.3	4.0
$(U)_4$	3.9	3.9
$(U)_5$	4.1	4.2
$(U)_6$	4.4	4.5
$(U)_7$	4.8	5.0

Experimental conditions as in Fig. 1 except that the binding was carried out with 100 pmol 30S ribosomal subunits at 16 mM Mg^{2+} with an incubation for 30 min at 0 °C.

the A site of 70S ribosomes, whereas the P site was exclusively occupied by deacylated tRNA^{Phe}. The evidence for this suggestion came from experiments which showed that no diphenylalanines were formed (as judged by peptide analysis) and none of the Phe-tRNA bound to the ribosome reacted with puromycin, that is, aminoacylated Phe-tRNA did not bind into the P site (data not shown).

In contrast, the degree of Phe-tRNA binding to 30S ribosomal subunits is independent of the oligouridylate chain length within the range of 3 to 7 (Table 1) and occurs to the same extent, regardless whether EF-Tu is present or not (Table 1). Thus each of the specific effects of EF-Tu described above requires 70S ribosomes.

The experiments with hexauridylates (Fig. 1) provided evidence that occupancy of the ribosomal P site by an uncharged tRNA was a prerequisite for subsequent enzymatic binding of Phe-tRNA^{Phe} to the 70S A site. To demonstrate that the occupation of the P site had to be codon-specific to permit subsequent enzymatic tRNA binding to the A site, the hexanucleotides AUGUUU, GUAUUU and UAUUUU were synthesised and used as templates. Four pure deacylated tRNAs ($tRNA_f^{Met}$, tRNA^{Val}, tRNA^{Tyr} and tRNA^{Lys}) were tested for this stimulatory activity. The results, summarised in Table 2, confirmed our predictions. EF-Tu-mediated Phe-tRNA^{Phe} binding was dependent on the presence of the tRNA cognate to the 5'-codon (Table 2). The combination of $tRNA_f^{Met}$ and AUGUUU gave the highest degree of Phe-tRNA^{Phe} binding, which was in each experiment above 40%. This effect was absolutely dependent on the presence of the 5'-AUG codon, since the stimulatory effect of $tRNA_f^{Met}$ was not observed with either GUAUUU or UAUUUU as templates (Table 2). This result is of special importance, since $tRNA_f^{Met}$ has a high intrinsic affinity for the P site[13]. It excludes the possibility that the observed enhancement of enzymatic Phe-tRNA^{Phe} binding to the A site with AUGUUU was only a consequence of the occupation of the P site by the initiator tRNA without concomitant codon–anticodon interaction. This was confirmed when use of tRNA^{Val} and tRNA^{Tyr} gave qualitatively similar codon-specific effects (Table 2). The effects of these two tRNAs on

Table 2 Enzymatic binding of Phe-tRNA^{Phe} to 70S ribosomes with AUGUUU, GUAUUU and UAUUUU is strictly dependent on the tRNA which is cognate to the first codon

Deacylated tRNA	Phe-tRNA^{Phe} bound (pmol)		
	AUGUUU	GUAUUU	UAUUUU
None	0.7	0.9	0.7
$tRNA_f^{Met}$	10.0	0.6	0.9
tRNA^{Val}	0.5	4.5	0.6
tRNA^{Tyr}	0.6	0.8	3.0
tRNA^{Lys}	0.5	0.6	0.5

Reaction conditions were as described in Fig. 1 except that the incubation mixtures contained 25 pmol 70S ribosomes, 25 pmol of pure [^{3}H]Phe-tRNA^{Phe}, 100 pmol EF-Tu, 5 nmol of hexanucleotide[10] and 50 pmol of pure deacylated tRNA as indicated.

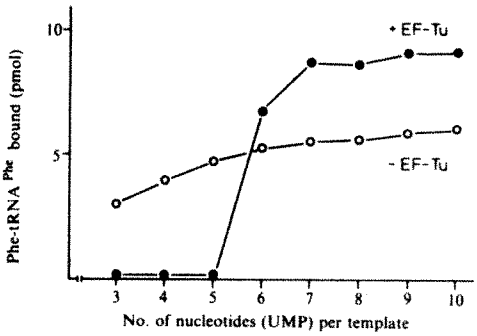

Fig. 2 Mg^{2+} dependence of the enzymatic (●) and nonenzymatic binding (○) of the Phe-tRNA^{Phe} to 70S ribosomes mediated by AUGUUU. Experimental conditions as in Table 2 except that the reaction mixtures contained 2 nmol AUGUUU and 50 pmol of pure deacylated $tRNA_f^{Met}$.

enzymatic Phe-tRNA^{Phe} binding were less marked than those seen with $tRNA_f^{Met}$, probably because of the lower affinity of deacylated non-initiator tRNA species for the ribosomal P site. tRNA^{Lys} had no effect (Table 2), which is as expected since the cognate codon for this tRNA (AAA) was not present in the templates.

Codon-specific occupation of the ribosomal P site with deacylated tRNA allows the subsequent binding of an aa-tRNA into the ribosomal A site to be studied in isolation, since peptidyl-transfer cannot occur in any of the systems described above. For AUGUUU/$tRNA_f^{Met}$ the active role of elongation factor EF-Tu in promoting aa-tRNA binding into the A site is not restricted to a unique Mg^{2+} concentration (Fig. 2). Negligible binding of Phe-tRNA^{Phe} to the ribosomes was observed from 5 to 15 mM Mg^{2+} in the absence of EF-Tu. However, in the presence of EF-Tu (and hence the ternary complex) maximal binding of Phe-tRNA^{Phe} was reached at and above 7 mM Mg^{2+} (Fig. 2).

Our findings are in accordance with the observations of others, who found a similar stimulation of enzymatic Phe-tRNA binding when the P site of poly (U)-programmed ribosomes was occupied either with *N*-acetyl-Phe-tRNA[14] or with peptidyl-tRNAs [15,16] but our data conflict with the conclusion[17] that the states of occupation of A and P sites are independent of one another. The latter experiments were, however, performed under nonphysiological conditions, namely at 20 mM Mg^{2+} and without elongation factor EF-Tu.

The experiments reported here prove that EF-Tu mediated Phe-tRNA^{Phe} binding to 70S ribosomes is possible if (1) the template $(N)_x$–UUU has a minimum chain length of 6 (Fig. 1) and (2) a tRNA is present which fits the 5'-neighbouring NNN codon. Non-cognate tRNAs are ineffective, even if they bind tightly to 70S ribosomes in the absence of their codon (for example, $tRNA_f^{Met}$; Table 2).

These observations can be explained by assuming that in physiological conditions (in the presence of EF-Tu and at low Mg^{2+} concentrations) the A site of the 70S ribosome can accommodate aa–tRNA only within the ternary complex EF-Tu · aa-tRNA · GTP and, even then, only when the P site is occupied by mRNA-cognate tRNA. Furthermore, the experiments strongly suggest that the A site only exists as such when the P site is so occupied. Further experiments will be required to show whether the codon-selected tRNA in the P site acts only as an effector molecule, which 'opens' the A site, or whether tRNA–tRNA interactions occurring within the ribosome are also involved.

Regardless of this uncertainty, our results show that codon–anticodon interaction is maintained by the P site-bound tRNA. Our results are consistent with conclusions drawn from recent experiments of Wurmbach and Nierhaus[18]. These authors analysed a series of purified deacylated tRNAs for their ability to block the P site binding of *N*-acetyl-Phe-tRNA to poly

(U)-programmed 70S ribosomes and to direct the same tRNA to theA site, and were able to show that only the cognate tRNA was effective.

The AUGUUU/$tRNA_f^{Met}$system may serve as an ideal and simple model system for investigations concerned solely with the binding of a ternary complex to the ribosomal A site, since the system is not dependent on the presence of initiation factors. Furthermore, the complexes of 70S ribosomes carrying Phe-$tRNA^{Phe}$ in the A site can be purified on a large scale by sucrose gradient centrifugation without loss of pre-bound Phe-tRNA (unpublished results). Thus the system may be useful for the study of the effects of some antibiotics and also for physicochemical investigations, such as fluorimetric studies, with tRNAs or templates specifically modified with flourescent probes.

Atmospheric lead pollution of grass grown in a background area in Denmark

LEAD in the atmosphere of the Northern Hemisphere originates mostly from lead-alkyl petrol additives emitted from car exhausts[1]. A small proportion of this lead—estimated at about 10%[2,3]—is deposited within 50–100 m of the road while the rest is presumably transported long distances before deposition. There are reports of increasing concentrations of lead in roadside vegetation with decreasing distance from the edge of the road[1,4,5]. This apparent lead contamination ceases beyond 100–200 m from the road, and it is said therefore that airborne lead is not a significant source of lead in crops in general[5–7], although there is circumstantial evidence to the contrary[8,9]. We report here, however, that the lead taken up by grass in a remote rural area is predominantly from the atmosphere.

Table 1 summarises evidence of airborne lead in background areas far from roads and towns throughout the world[10,11]. If airborne lead were present everywhere, aerial deposition on vegetation could account for part of the lead content found in plants. Lead concentrations reported for protected plant organs are normally very much lower than for unprotected parts. The average rate of deposition of lead from the atmosphere in Denmark is about 1 mg m^{-2} per 30 d[12], which is much greater than the rate of accumulation of lead in an average crop, 0.1–0.2 mg m^{-2} per 30 d. To determine the uptake of lead by plant roots, specific activity (counts per 10^3 s per μg Pb) was measured in soil labelled with ^{210}Pb and compared with the specific activity in the plants. Any difference in specific activity in the plants had to be the result of uptake of nonradioactive lead by the plants. The site of our experiment was the experimental station at Højbakkegaard in Taastrup, west of Copenhagen. We know of no industrial sources of lead contamination within a radius of 5 km. The E66 highway runs east–west 1 km to the south (22,000 cars per 24 h), and the area is surrounded by agricultural farmland and forests.

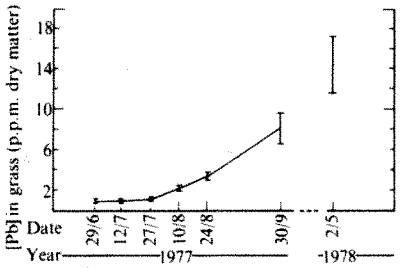

Fig. 1 Lead concentration in grass during growing season, p.p.m. dry matter. Vertical bars indicate $\pm\sigma$ on observations.

We carried out a pot experiment involving three different soils and a crop of Italian rye-grass (*Lolium multiflorum* Lam.). Pots were fertilised with normal amounts of N, P and K at the beginning of the season to give a normal growth rate. Six cuttings were taken during 1977 and one in 1978. Soils were labelled with ^{210}Pb (0.02 mCi per kg soil) 18 months before sowing. During this period the soils were mixed thoroughly several times and wetted to obtain isotopic equilibrium.

The surface area of the polyethylene pots was 250 cm^2, and the soil was 20 cm deep. Below the soil was a layer of 5 cm of acid-washed quartz on top of filter paper. Drainage was provided through a hole (1 cm diameter) at the bottom of the pot. The pots were sunk into a lawn, so that their edges were level with the soil surface, and placed on a layer of sand to secure drainage. After the experiment no roots could be seen emerging from the drainage hole in the pots. The height of the lawn was kept the same as that of the grass in the pots.

During the growing season the bulk precipitation of lead and the content of lead in the ambient air around the experimental station were measured. The rain was collected in a polyethylene funnel/bottle system and acidified with HNO_3 as preservant. Aerosols were sampled on an OECD standard sampler[15] modified with a 5-cm filter (Whatman no. 1), and sampling about 2 m^3 d^{-1}. The filters were extracted in 1M HNO_3 (boiling) before analysis.

Plant samples were dried in paper bags at 50 °C, and digested in HNO_3: $HClO_4$ (10:1). Soil samples were treated with three extractants to assess differences in isotopic labelling (1:1 HNO_3, 0.02 M EDTA or ammonium acetate (*p*H ~ 4, 8)). The determinations of lead in prepared sample solutions were made on atomic absorption spectroscopy with graphite atomiser[13]. Solvent extraction (DDDC in xylene) was used to eliminate interference[16]. The activity of ^{210}Pb in digests or extracts was measured by crystal scintillation counting.

A major objection to using radioactive tracers in a soil

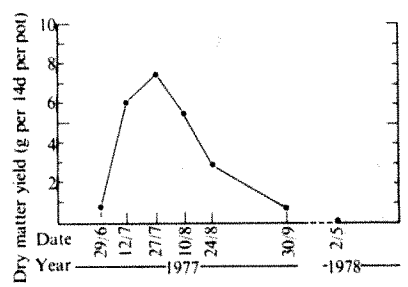

Fig. 2 Rate of dry matter yield, expressed as grams of dry matter (collected) per 14 days per pot.

experiment is the uncertainty of isotopic equilibration. However, as three methods of soil extraction gave the same specific activity, we believe that the added ^{210}Pb had attained true isotopic equilibrium with the indigenous lead. Further, if the added ^{210}Pb was less strongly bound than the indigenous lead, the observed specific activity in the grass would be too high, leading to an underestimation of the atmospheric lead supply to the plant.

The characteristics of the soils are given in Table 2. Average lead deposition and the average ambient air concentration are shown in Table 1. The values observed at the experimental site are higher than those found at remote sites, but they are within the range found in rural areas of western Europe and the US.

The total lead concentrations in the plant material that had been exposed to the atmosphere varied from ~0.6 to 8 p.p.m. dry matter for plants grown in the summer, while concentrations were considerably greater for those grown during the winter. The range of lead concentrations found is quite similar to the values summarised by Höll and Hampp[1] for grasses sampled in background locations. In research on the application of sludge to the land conducted in cooperation with three state research farms in Denmark we have found that the concentration of lead in grass from untreated fields is in the range 1–6 p.p.m. of dry matter, most values averaging around 2 p.p.m.

The observed increase in the lead concentration during the growing season is consistent with the findings of other authors[6,14]. This phenomenon may be explained as a decreasing dilution of the atmospherically supplied lead with newly grown grass, due to the decrease in growth rate after the midsummer peak.

Table 2 Characteristics of soils in the pot experiment

Origin and type of soil*	Rønhave (loam)	Askov (sandy loam)	Lundgaard (sandy)
Clay % < 0.002 mm	16	11	3
Silt % 0.002–0.02 mm	21	12	4
Fine sand % 0.02–0.2 mm	37	38	26
Coarse sand % 0.2–2 mm	24	37	65
Organic matter %	2	3	2
CEC mEqv per 100 g dry matter	13	12	5
pH_{CaCl_2}	6.6	6.3	4.6
Total lead p.p.m. in dry weight	17.3	14.4	11.1

* The soils are arable top soils (0–25 cm).

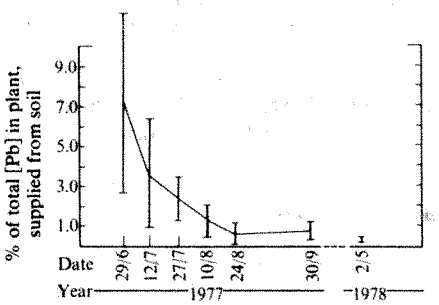

Fig. 3 Root uptake of lead expressed in percentages of total lead supply to plant. Vertical bars indicate $\pm\sigma$ on observations.

Figure 2 shows the average yield of dry matter per pot per 14 days. Yields are comparable to normal yields on grassland, being of the order of 6–10 ton of dry matter per hectare per season. The specific activity of lead in the soil was 1,500–3,100 counts per 10^3 s per μg Pb, and in the grass 4–200 counts per 10^3 s per μg Pb.

The total concentration of lead in the grass, and the calculated percentage of lead in the grass coming from the soil did not differ significantly between the three soils used in spite of differences in *p*H and texture. Figures 1–3 are thus the averages of results obtained for the three soils in six pots.

The percentage of lead in the grass crop originating from the soil was calculated as:

$$\%\ Pb_{soil} = \frac{\text{Specific activity of Pb in crop}}{\text{Specific activity of Pb in soil}} \times 100$$

Figure 3 shows that it was 0.2–10% of the total lead content of the green parts of the grass. This result will not be greatly affected by the earlier discussed possibility of isotopic inequilibrium in the soils, as an underestimation of the atmospheric contribution is hardly important when it is more than 90%. Thus deposition of atmospheric lead on the plant surface was responsible for between 90 and 99% of total lead content in the grass in this typical background area in Denmark.

We thank the staff of the experimental station at Taastrup for valuable help. This project was financed in part by the Danish Agricultural and Veterinary Research Council.

Richard Dawkins

Sociobiology: Sense or Nonsense? By Michael Ruse. Pp. 231. (D. Reidel: Dordrecht, The Netherlands, and Boston, Massachusetts, 1979.)

WHAT on earth is sociobiology? If philosophers have a role to play in science it presumably includes clearing up semantic confusion. Michael Ruse is a distinguished philosopher of biology who would agree: "I am a philosopher, and for me, in John Locke's great words, 'it is ambition enough to be employed as an under-labourer in clearing the ground a little and removing some of the rubbish that lies in the way of knowledge . . . ' " (p164). Yet, after reading this sensible and pleasantly written book, I remain unable to answer the question with which I began. What is sociobiology and who are the sociobiologists?

Well, if anybody is a sociobiologist it is E. O. Wilson, so his definition must be taken seriously: ". . . the systematic study of the biological basis of all social behavior" (*Sociobiology: The New Synthesis;* Harvard University Press, 1975). A neutral discipline then, like history or geology. Geology or history as such cannot be true or false, yet Ruse debates the "truth" of sociobiology, and whether it is sense or nonsense. I sympathise. However neutral Wilson's definition may be, the widespread identification of "sociobiology" with a school of thought is an undeniable fact of current biological sociology, a linguistic oddity whose only recent biological parallel is the popular transmutation of "ecology" from a scientific discipline to a political opinion.

What, then, is this cluster of ideas, this bundle of concepts that have become linked in people's minds both with each other and with the name sociobiology? The answer is complicated because it depends on whether you read biologists or social scientists. Ruse has read both and absorbed both meanings, apparently without realising it. I will return to the social scientists' meaning later. The biological cluster is well represented by section headings in Ruse's chapter on "The Sociobiology of Animals": kin-selection, parental investment, reciprocal altruism, evolutionarily stable strategy. How the cluster came to be linked in our collective mind is not clear. Wilson's *Sociobiology* can hardly be the common denominator, for, although these concepts are mostly mentioned there, so is almost everything else. As befits his own definition, Wilson rightly devotes more space to the comparative study of social systems and their correlation with environmental variables, important topics which seem to be absent from the mysterious cluster and absent from Ruse's book.

My own slightly irreverent epitome ("sociobiology is the branch of ethology inspired by W. D. Hamilton") leaves the timing unexplained. A little research in *Science Citation Index* shows that Hamilton's now famous papers in the 1964 *Journal of Theoretical Biology* were seldom cited in the nine years up to 1973. Then, in 1974, the year before *Sociobiology,* the curve suddenly turns up sharply and has soared (almost exactly exponentially) ever since. When concepts that have been ignored a long time suddenly group themselves together and proliferate like fire through the imaginations of scientists, then philosophers and historians of science should have interesting things to say. Unless, that is, they are lured away from constructive analysis by a preoccupation with destructive criticism and the supposed need to reply to it. In this respect Ruse's book is a disappointment.

It is, however, not all disappointing. Ruse may not define his subject, but he does a good job of discussing it, whatever it is. He writes in an easy, unpretentious style, and his aim is clearly to communicate with his readers rather than to show off to them. "Of course, if I get my biology wrong I expect to be criticised by biologists; but that is nothing to what I expect from philosophers if I get my philosophy wrong . . .". This particular biologist has no complaints about the chapter on "The Sociobiology of Animals"; it might have been written by a biologist. Oddly enough, my most serious worry is over an issue that could be called philosophical, the one known by the cliché of nature and nurture.

The trouble begins to surface in the chapter on "The Positive Evidence" (for human sociobiology), where he makes the following strange remark: "I take it that the problem at issue is the extent to which human behaviour, specifically social behaviour, is essentially a function of the genes, where, by this, is meant that the behaviour will manifest itself under normally occuring environments without the need for any special learning input". We have now moved on to the social scientists' understanding of "sociobiology", which has nothing to do with Wilson's neutral definition (unless perhaps you think "biological" means "genetic"), nor with my "mysterious cluster". Sociobiologists are apparently supposed to believe that human behaviour is governed by genes as opposed to learning (I even recently heard Sir Cyril Burt quoted, not by Ruse of course, as an example of a sociobiologist!).

Let me briefly put my finger on this muddle, for it is a common one and I know it well. Whoever the sociobiologists may be, nobody would deny that they are interested in behaviour as Darwinian adaptation. In order to talk about the Darwinian evolution of anything we have to postulate the sometime existence of genetic *differences* between individuals — otherwise there would have been nothing for selection to choose between. This does not mean there has to be genetic variance any longer: any characteristic that has been strongly favoured by selection is likely now to have low heritability, the genetic variance having been used up. More importantly, a genetic contribution to differences is not the same as (indeed, it has nothing whatever to do with) behaviour manifesting itself "without the need for any special learning input". As Konrad Lorenz and others have emphasised for years, learned behaviour must itself be subject to Darwinian, therefore genetic, selection. Happily, Ruse does not fall for the even more extreme muddle, beloved of

extreme hereditarians and their unwitting allies among "scientific radicals", of equating genetic variance with irrevocable, unswerving genetic determinism.

Ruse is rather good at dealing with such people. In America there are some genuinely good scientists who have severely criticised sociobiology, and we have to listen to them. Ruse does so, understands them, agrees with them in places, but finally remains largely unimpressed. He also gives some reassuring pats to the ruffled feathers of social scientists who fear imminent takeover by a rapacious biological imperialism.

I have concentrated on places where the book could have been improved, but there is good in it and I hope it will be read by those who have managed to retain an interest in this rather overpublicised controversy. Ruse's sense of balance and agreeable style are well shown in his closing sentences: ". . . I am far from convinced that human sociobiologists have yet made their case. What I do plead is that their sins are not as grave as their critics argue. Human sociobiology should be given the chance to prove its worth. If it cannot deliver on its promises, it will collapse soon enough; but if it does prove viable, then its success could pay scientific dividends of the highest order". Who will disagree? □

Richard Dawkins is Lecturer in Zoology at the University of Oxford, UK.

Interpreting visual motion

The Interpretation of Visual Motion. By Shimon Ullman. Pp. 229. (MIT Press: Cambridge, Massachusetts, and London, UK, 1979.) $17.50; £11.40.

THIS book is a slight revision and extension of Ullman's doctoral thesis researched at the Artificial Intelligence Laboratory of MIT. Various parts of it have also been published independently (in somewhat different form) in various journals (*Perception, Perception and Psychophysics, Proc. R. Soc. London).* Nevertheless, the book is worth prossessing in its own right if you are an experimental psychologist or an artificial intelligence researcher interested in vision, especially in motion perception, primarily because of its special methodological qualities.

Ullman investigates the phenomenon of apparent (or phi) motion, the illusion enabling us to watch television or movie pictures despite their discrete presentation. The phenomenon is conceptualised as a computational problem and is divided into two parts, each of which is studied independently. Solving a computational problem includes specifying the goal of the computation, and then investigating possible (and plausible) methods for attaining the goal. A theory of what is being computed is thus an integral part of the understanding of the information processing system being studied, in this case the human visual system. The phi phenomenon is seen to establish the correspondences between the elements in two successive "snap-shots" of a scene, and then interpreting the resulting displacements as motions of the objects.

Ullman shows that the correspondence computation amounts to computing the so-called minimal mapping, the match that minimises costs over the covers of the graph of possible (probability weighted) pairings. He shows that the initial candidates for a set of possible pairings for a given element in one snapshot can be restricted to elements (in the second snapshot) lying within some limited distance radius of this element. This means that the correspondence process can be effected by a simple network of locally competing processors of uniform structure. Furthermore, Ullman shows that the domain of the computation is a "token space" (D. Marr's "primal sketch": *Phil. Trans. R. Soc.* **B275**, 483-524: 1976), a symbolic representation consisting of blobs, line segments, edge fragments and the like, which is the result of pre-processing the raw image intensity distributions.

The next stage consists of interpreting the displacements obtained. Ullman develops the notion of a "rigidity test", operating locally on a nucleus of elements and leading to decisions about whether the displacements associated with the nucleus can possibly represent (and result from) a rigid object in motion. The analysis is based on his "structure-from-motion" theorem which states that the structure (relative position) of four non-planar points is uniquely recoverable from three orthographic projections. Such an interpretation does not assume any recognition of, or familiarity with the objects in question.

Finally, Ullman discusses "motion-from-structure" situations in which motion is established as a "filling-in" process linking two objects recognised as being an instance of the same object in the two successive static snapshots. He compares the two motion-analysing mechanisms and argues that various interpreting processes (analysis of static "snapshots", "motion-from-structure", "structure-from-motion", and so on) all contribute to one common representation and that they must compete or co-operate to produce the final result, the percept.

This monograph is clearly written. Within the limits he has set for himself, Ullman has achieved a great deal. This is an excellent and important piece of work.

Protein synthesis inhibitors

Inhibitors of Protein Biosynthesis. By David Vazquez. Pp. 312. (Springer: Berlin, Heidelberg and New York, 1979.) $32.50.

NO matter how hard you try to keep up with the literature in this field, you usually find it slipping away from you. Well, here's a good chance to catch up with all of it. In this comprehensive survey David Vazquez cites 1017 references (I think), of which a mere 100 originated from his laboratory, and pulls so many rabbits out of the hat that one feels he could have directed *Watership Down.*

The book is bulging with information including the structures, empirical formulae, molecular weights (many thanks) and synonyms of antibiotics together with the names of the producing organisms. The subject of synonyms is particularly intractable and this reviewer is now glad to know that multhiomycin and nosiheptide are the same thing, to say nothing of anthelmycin and hikizimycin. All your old favourites are here and, when you turn to the appropriate Figure, you'll probably find they have a few cousins you didn't know about. It's inevitable (isn't it?) that something should have been omitted, but I'll have to check carefully before I complain that pulvomycin should have been included with the rest of the kirromycin group in Fig. 42. (You never know, it could be an alias for efrotomycin!)

All the alkaloids are in here too and when botanists have finished talking about them as being herbivore-repellents, or nitrogen excretion products, or whatever, they should note just how many of them are ribosome-inhibitors. The same is true for various other plant products known more generally as lectins and agglutinins.

Of course the main aim of this book is to deal with the action of inhibitors of protein synthesis. So, if you want to know what others think they know about the mode of action of any antibiotic or drug, David Vazquez will tell you. For this reason the book does not read like an essay; with so many facts and figures (61 of the latter) it is meant to be used as a reference book. As such it should find a place in research laboratories and in reference collections, although it cannot be recommended for students. However, no-one working in the fields of antibiotic action, protein synthesis or ribosome structure-function analysis should be without it. I warmly recommend it.

Eric Cundliffe

Eric Cundliffe is Lecturer in Biochemistry at the University of Leicester, UK.

Human information processing

Strategies of Information Processing. Edited by G. Underwood. Pp.455. (Academic: London and New York, 1978.) £20.

IN the 1950s and early 1960s scientists who discussed selective attention, perceptual discrimination, reading and the choice of responses called themselves Human Experimental Psychologists. They were earnest people prone to strange methodological obsessions. They used models derived from the theory of simple, passive communications systems and metrics derived from information theory and communications theory. Nowadays the same people are relaxed and expansive. Most have abandoned interest in methodology or metrics and many even in experiments. Nowadays we are Cognitive Psychologists. Among very young research workers it is a dogma that this euphoric transformation (including, incidentally, the titling of three prestigeous journals, at least two large departments of psychology, four honorific chairs and an Open University course) came about as a result of a single book, Ulrich Neisser's *Cognitive Psychology* published in 1967. Older workers are embarrassed to enjoy their new liberties without knowing what they must believe to earn them. They find it strange that a very slight book should be credited with a Cognitive Revolution and, by and large, those of us who still do research do the same things we have always done under new titles.

The middle-aged are not prone to rocking boats - even Ships of Fools - so it is right that complaints should come from a young research worker, Geoffrey Underwood, who has edited a collection of 12 essays under the title *Strategies of Information Processing*. Underwood takes his role as challenger of the new establishment as seriously as if he were writing in 1958. He insists that his book is a "statement of faith" (Preface, p1). Apparently he believes that classical models of human information processing may be revived within the context of models drawn from the theory of self-optimising control systems. He feels that these rehabilitated models will provide means for empirical investigations of intention, and purpose, and even perhaps sensible approaches to problems of consciousness. That is they will simultaneously teach Cognitive Psychologists to do proper experiments and disarm their critics (such as Gauld, Shotter and the anti-empiricists) who believe that the most important problems of human psychology are inaccessible to laboratory investigation.

Older research workers may be expected to brighten at this news. The dear familiar models of our youth are to be justified as the basis of the next conceptual advance. We have always lived beyond the current fashion without knowing it.

The publication of these papers will not quite achieve this. Critics who objected to "mechanistic" psychology in the guise of simple communications models are not likely to be placated by descriptions of purpose in terms of loops and branches of computer programs or conceptions of intentionality paraphrased as the search for the optimum among possible paths in a decision tree.

Control theory models have been common in ethnology since the late 1960s and excellent summaries of their applications by MacFarland, Oatley and Toates have formed the basis of undergraduate courses for some years. The omission of recent work on ethological systems is a sad ommission from this book. There is little about the contributions which suggests any striking novelty of approach — or even any daring retrogression. Neville Moray now provides a clear and useful summary of the lectures on optimisation of informational selectivity which he has given over the past six years. Max Coltheart usefully reviews his recent thinking about lexical access during reading. A review of hemispheric asymmetry effects by M.P. Bryden provides an updated bibliography of the unreliable literature in a field recently very popular among Cognitive Psychologists. The inclusion of the word *strategy* in the titles of contributions seems to reflect loyalty to the editor rather than any worked-out change in theoretical approach. For example, C.I. Howarth reviews his own, excellent and sadly neglected, work on motor skillls under the title "Strategies in the Control of Movement". There are useful digests of research on speech perception by Cole and Jakimek and on eye-movements during reading by Alan Kennedy. One paper certainly has a novel theme. John Fox provides an exegesis of hypothetical neurology of vision proposed by Dr. Marr. This work is fascinating, and original, but Marr's own papers are more lucid, much richer in their implications, more rigorous in argument and now generally available. Fox's paper is cheerful and entertaining, but why is it necessary for him to act as a sort of intellectual Basil Brush on behalf of a very talented colleague?

In sum, this is a very handy reference work, invaluable for teaching courses to third-year undergraduates. It does repeatedly stress the point that human beings must be considered as active rather than passive self-optimising systems and it illustrates this emphasis with data from a wide range of experimental situations. Librarians and teachers will find this a useful book to buy, but active research workers will be busy with the current issues of journals and have read it all long ago.

Patrick Rabbitt

Patrick Rabbitt is a Fellow of The Queen's College, and Lecturer in the Department of Experimental Psychology, University of Oxford.

Biological transport

Mechanics and Energetics of Biological Transport. By E. Heinz. Pp. 159. (Springer: Berlin, Heidelberg and New York, 1978.) DM 49; $24.50.

THE swift development of biological transport as a discipline in its own right over the past two or three decades has proved something of a phenomenon, and has brought in its wake the publication of a near-avalanche of books. Predictably, the majority of these are edited proceedings of meetings or collections of review articles, and suffer from the lack of coherence both in style and content peculiar to this particular genre. Some notable exceptions are the well-known treatises of Stein, Schoffeniels, Kotyk and Janácek, and more recently Christensen, each of which is written from a highly individual standpoint and intended as an all-embracing treatment. What is missing at present is a comprehensive analysis devoted entirely to the energy transactions of the transport process, which would draw together material scattered in a forest of original reports and reviews.

In this regard, the monograph under consideration (offset printed from a typed manuscript) presents, first and foremost, a concise compilation of *kinetic* models and formulae. Still, a commendably broad range of topics is included, covering one-flow and two-flow systems, along with an approach to the description of coupled transport in terms of nonequilibrium thermodynamics. Among the topics touched on in summary fashion are diffusion, flux ratios, specificity, carriers and channels, coupling phenomena, isotope interaction, and primary and secondary active transport. Some examples indicating the range of specific coupled systems discussed are the ATPases (Ca^{2+}-activated, Na^+-K^+-activated, and proton translocating), the redox proton pump, and the phosphotransferase systems. For many readers the brevity of the treatment will be a great advantage, and the ready accessibility of a large number of formulae to suit every occasion (and taste) may well be, for some, the most attractive feature of the book.

However, this is by no means an eclectic account of transport bioenergetics. Quite the opposite is the case: it bears the unmistakable stamp of a single school. To readers familiar with kinetics this may not

Nature Vol. 280 2 August 1979

be uncongenial. The author places great emphasis on the so-called "Law of Mass Action" treatment, in which transport phenomena are formally described as if they were chemical reactions. The implication is that coupled processes such as active transport are intrinsically stoichiometric, that is, completely coupled, and that any slippage must be attributed to internal or external leakage, or to "leakage" of the driving reaction in the case of a pump. This view does not comprehend the wider possibility that incomplete coupling may be a fundamental property of the system and even confer on it some regulatory advantages. Nevertheless, a serious attempt has been made to combine and integrate the kinetic and thermodynamic analyses. It might have succeeded better if certain lapses in rigour had been eliminated — for example, the present reader was surprised to find the standard affinity being put forward as the effective driving force in active transport, and to be informed that completeness of coupling implies an efficiency of 100%.

Although the author has certainly provided a unified and consistent exposition of his theme, lacunae occur which are troublesome. Some of these are to be anticipated from the preface, in which he states: "The simplifying assumptions may often be unreal. Hence the equations should not be applied uncritically . . . ," and later ". . . no attempt has been made to quote the underlying literature completely and according to priority". Indeed, the sparing use of references will undoubtedly make critical evaluation of the equations a hard task for the tyro. Perhaps the most important omission is the absence of experimental data which might have been used to illustrate the usefulness and range of applicability of the theory.

The book is marred by the usual sprinkling of misprints, but is handsomely bound, as behoves a manual to be thumbed through at frequent intervals. With some reservations I recommend its purchase, suspecting that its utility will be greatest for confirmed *afficionados*.

Semiconductor systems

Problems of Linear Electron (Polaron) Transport Theory in Semiconductors. By M.I. Klinger. Pp. 931. (Pergamon: Oxford, 1979.) £62.50.

THIS is a very large and expensive addition to Pergamon's Natural Philosophy series, being some nine hundred pages in length. It covers the theory of linear transport and other properties of electrons in a range of semiconductor systems which become gradually more disordered as the book proceeds (reflecting the research trends of the past three decades). As one might expect in such a large book on a restricted topic, there is a vast amount of detail, with every major (and in some areas minor) theory described.

The first two chapters form an introduction to transport and solid-state theory. The interaction of an electron with the lattice vibrations to form polarons is then described in various mathematical and physical approximations. The dynamic and transport properties of the polaron in crystals are considered in the following three, very long, chapters. The final part of the book attempts to draw together the theories of electron conduction in disordered semiconductors.

The content of the book is, in one respect, excellent, in that almost everything one could wish for has been covered concerning the theoretical development of the subject up to the mid-1970s. It is not a textbook in the normal sense; however, there is a strong tendency to present the problems and the various solutions with little explanation. In some areas it was necessary to go back to the original papers to understand the author's over-concise version. Throughout, the emphasis is on the formalistic development of the subject where possible, experiment playing only a very minor role. Even with this omission, the treatment is very condensed and mathematical, especially in the first half of the book. In consequence, however, a large range of properties and physical models have been covered.

Very few concessions are made to the reader: a very high mathematical ability and a good background knowledge are assumed, making this a book for the theoretical specialist rather than the general research worker. In a field where experiment and simple physical models have played such a large part in aiding our understanding, especially in the disordered systems, this is unfortunate and gives a distorted view.

In conclusion this is a rather lopsided book; a more critical approach to the content could have reduced the size and still have allowed room for a more balanced treatment of the subject. What one has here is a very specialised reference book, undoubtedly very useful to a restricted number of people but not really fulfilling the need of the many experimental workers in this field.

J.C. Inkson

J.C. Inkson is a staff member of the theoretical group at the Cavendish Laboratory, University of Cambridge, UK.

Materials science

Science of Materials. By W. Brostow. Pp. 436. (Wiley-Interscience: Chichester, UK, and New York, 1979.) £20.

THIS book is intended as an undergraduate text in materials science, but differs significantly from existing books in its approach. This difference can best be summarized by saying that Professor Brostow has given us a physicist's view of materials science rather than a materials scientist's! Thus the solid state is not introduced until the seventh chapter, the first six being devoted to mathematical techniques, statistical mechanics, intermolecular forces, gases, liquids and solutions.

This early portion of the book is excellent, especially the treatment of statistical mechanics which is rarely introduced in any depth in materials texts. The treatment of intermolecular forces is also refreshing, escaping as it does from the simplistic classification of chemical bonds usually presented in books for undergraduates.

The amount of space devoted to the physics of matter means that some essential topics such as phase equilibria, crystal structure and defects are treated in a very basic fashion, appropriate only to a first-year level. This tendency to touch on subjects without dealing with them adequately increases as the book proceeds. Thus, polymeric materials are covered completely in eight pages (although rubberlike elasticity provides a further six pages in a later chapter.) Composite materials have a separate chapter, but more than half of its twelve pages are devoted to wood, while fibre reinforcement is dismissed in less than a single page. The mechanical properties of all forms of solids and liquids occupy a single chapter and strengthening mechanisms in crystalline solids receive only a three-page coverage. Electrical and dielectric properties are treated at what seems to be a sub-degree level, and a final chapter on the testing of materials contains only four pages of text and no diagrams.

In a book of manageable size, of course, it is quite impossible to achieve both depth and breadth. Professor Brostow has settled for depth in the physics of matter and breadth in materials science, and this balance will no doubt appeal to teachers of physics. By the same token, however, it will not satisfy the needs of materials and engineering undergraduates. The high cost of the present hardcover edition will also discourage its use as an undergraduate text.

E.H. Andrews

E. H. Andrews is Professor and Head of the Department of Materials Science at Queen Mary College, University of London, UK.

COMING SHORTLY

Brain Research Reviews

a volume of Brain Research devoted to the publication of high quality review articles.

Editor-in-chief: D.P. Purpura, Bronx, N.Y

The recent remarkable growth of neuroscience research and the progressively increasing problem of assimilating new data have greatly enhanced the value of well-organized, topical Review Articles. At the same time, pressures for publication space in Brain Research for original Research Reports and Short Communications have limited the number of meritorious Review Articles that can be accommodated annually. To avoid competition for available space a supplementary volume entitled, Brain Research Reviews, will be published beginning in July 1979 and thereafter. This volume will be devoted to Review Articles and occasionally long research papers with extensive review components, meeting the demands for rapid publication of analytical surveys that define heuristic hypothesis and provide new insights into brain mechanisms.

Brain Research Reviews commences publication in July 1979 and is produced within the same editorial and production framework as Brain Research itself. It forms an integral part of the subscription to Brain Research, but is also available separately to non-subscribers.

Brain Research Reviews
1979 Volume 180/BRR Volume I.
Subscription Price: US $ 73.25/Dfl. 150.00 including postage.

Brain Research
1979 Volumes 159-180 (22 volumes in 52 issues)
Subscription Price: US $ 1610.00/Dfl 3300.00

Contents of the first issue:

- **Sets of Neurons in Somatic Cerebral Cortex of the Cat and Their Ontogeny:** *Michael D. Mann, Omaha, NE, U.S.A.*
- **Quantitative In Vivo Autoradiography with Positron Emission Tomography:** *Marcus E. Raichle, St. Louis, MO, U.S.A.*
- **Behavioral Functions of the Reticular Formation:** *Jerome M. Siegel, Los Angeles, CA, U.S.A.*
- **Theories of the Dorsal Bundle Extinction Effect:** *Stephen T. Mason, Vancouver, Canada and Susan D. Iversen, Cambridge, U.K.*

PLANT BREEDING AND GENETICS IN HORTICULTURE

C. North

Macmillans latest addition to their successful **Science in Horticulture Series.**

This is a concise but comprehensive introduction to plant breeding and genetics in horticulture. It has been designed to suit the needs of those taking the National Diploma in Horticulture, the new HND, or degree courses at universities. This is an inexpensive volume by an experienced horticulturalist which will be an essential text for the student and an invaluable aid to the commercial grower and keen amateur gardener.
£4.95 0 333 23581 9

Other titles in the series include:
Bleasdale: Plant Physiology in relation to Horticulture
Flegmann and George: Soils and other Growth Media
Winter: Water, Soil and the Plant
Sargent: Economics in Horticulture

For further details of any of these titles please contact The Publicity Department, The Macmillan Press, Little Essex Street, London WC2R 3LF.

obituary

Dennis Gabor, 1900-1979

DENNIS GABOR, who received the Nobel Prize for Physics in 1972, for the invention of holography, died on 9 February 1979. One can surmise that he would have approved of such a one-sentence summary — holography was the crowning achievement, contemplated with great pleasure. Yet, it gives a distorting emphasis on a man who contributed radically new ideas to a number of quite distinct areas of applied physics, and who moved with effortless facility across the cultural divide.

Gabor was born in 1900 in Budapest, where he spent all his school days and completed three years at the Technical University. At the age of 21, he moved to the Technische Hochschule in Berlin, where, after receiving his Diploma, he commenced his doctorate studies under Professor Mathias. These centered on the use of cathode ray tubes for the observations of transient waveforms — thereby initiating a development, which has continued to this day, always in pursuit of the faster transients that have marked the path of progress in electronics. A by-product of this research was the development of the first electron lens; it had been known for some time that electrons could be focused by means of a 'concentrating coil', but it was Gabor's use of a magnetic circuit to concentrate the magnetic field over a short region which led to the first practical lens. Although he did not, at the time, fully understand its mode of action (it was just before the celebrated paper by Busch which marks the beginnings of modern electron optics), the invention was to play an important role in the realisation of the first electron microscope. In fact, the first demonstration of such a microscope by Borries and Ruska used the actual lens created by Gabor.

Gabor had himself speculated on the possibility of realising an electron microscope, as he has recounted in a fascinating article on the History of the Invention of the Electronmicroscope (*Elektrotech. Z. Ausg. A.* **78**, no. 15, 522-30, 1957) — but enthusiasm for undertaking the development was dampened by the expectation that any objects of interest would be rapidly carbonized by the electron beam. By the time Borries and Ruska embarked on the venture, Gabor had moved to the Siemens

Research Laboratory.

It was a narrow escape from greatness at an early age. Perhaps that early disappointment served to sharpen his subsequent enthusiasm for the inventive process; Shockley has attributed his invention of the junction transistor to his chagrin at having missed the earlier point-contact device.

The work at Siemens was largely devoted to a new type of gas discharge lamp. Whilst this research failed to lead to a commercially exploitable product, it marked the beginning of a life-long interest in the plasma state and its applications. It also led to a move to the Central Research Laboratories of B.T.H., Rugby, in 1933 — Gabor's response to the election of Adolf Hitler in Germany. The move to Rugby was facilitated by inspired talent-spotting on the part of Professor T. E. Allibone.

While continuing his work on gas discharge lamps, Gabor never entirely abandoned his interest in electron optics. He invented what we would now call a mechanical analogue computer for electron trajectory tracing; coincidentally with Irving Langmuir, he discovered the basic limitations on electron density in electron optical systems.

During the war, by reason of his status as an alien, Gabor was not able to contribute to the main stream of research — it was a time when the damning fact of foreign origin was more than a match for rational assessment. He was, nonetheless, able to make pioneering contributions to infra-red imaging and to develop a deeper understanding of the interaction between electrons and electromagnetic fields, the latter leading to a series of classic papers published in the last two years of the war. It also enabled him to continue work on electron optics and, above all, to do battle with what he perceived as the key problem — how to improve the quality of electron optical lenses. The constraints imposed by Laplace's equation deprive the electron optical designer of most of the weapons which are available in classical optics. The aberrations of electron optical lenses seemed to bar the path to the achievement of the ultra high resolution of which electron microscopes should have been capable — a resolution which could image single atoms.

Gabor tried to find room for manoeuvre by suggesting the introduction of space charge into lenses, to correct the aberrations — a technique which, as it eventually turned out, could not be effective, on account of the blurring occasioned by direct electron-electron interaction. Then, in 1947, quite suddenly, he perceived that the way to deal with bad lenses was not to strive to make them a little better, but, rather, to get rid of them altogether. The strategy envisaged by Gabor was made up of a number of quite distinct and quite brilliant insights — the ability to record the phase of a wavefront using materials sensitive only to intensity, by including a 'reference' wave; the possibility of recovering the information contained in the original wave by a reconstruction process with another, complementary wave; the recognition that the recording and reconstruction waves need not have the same wavelength — that an electron 'hologram' might be reconstructed at optical wavelengths. Gabor was able to demonstrate the principle at optical wavelengths, using the most coherent source then available — a mercury arc illuminating a pin hole. He published the results in a celebrated communication to *Nature* in 1948. It was a long way from the bold scheme envisaged for improving electron micrographs;

indeed, to this day, such improvements have not been realised — though the hope of eventual success is not dead.

Gabor then developed a comprehensive theory of holography, but few more experiments were conducted for a dozen years. It was not until the invention of the laser provided experimenters with highly coherent sources that holography had its second birth, in a series of inspired researches undertaken by Leith and Upatnieks.

The subsequent story of holography is one of explosive growth. It is now the basis of a large and growing industry; it has inspired new forms of art. It is still far too early to assess its ultimate impact on science, technology and the conduct of human affairs.

How should such a discovery be weighed and judged? Gabor, himself, wondered how one should assess the value of a discovery in applied science, in the aforementioned paper on the history of the electron microscope. The following is a translation from the German of one of the opening paragraphs in that paper:

'It is hardly to be debated that those whose work is most highly regarded are those who have pioneered a new field which has subsequently been shown to be fertile. In this there is an element of luck, possibly even of injustice; honours are not bestowed — as they are, for example in mathematics — in proportion to the mental effort required to reach the result. In fact, I would go further and suggest that if a scientific achievement is to receive the highest accolade, it should not be wholly rational; there must be some element of boldness and risk. We regard the discovery of electromagnetic waves by Hertz as a greater achievement than Hamilton's theory of conical refraction not only because Hamilton's work put the finishing touch to the theory of crystal optics whilst in contrast, Hertz opened up a wide and new field, but also because, when Hertz began his classic investigations, Maxwell's theory was by no means established; moreover, there was not the slightest ground for the expectation that the conductivity of the electric spark could decay in 10^{-9} seconds. This was a matter of boldness and risk — not one of logical expectation.'

The passage was written with reference to electron microscopy. It was 1957, and Gabor certainly had not the slightest expectation that holography could ever be viewed in such terms. Certainly, the research students he acquired when he moved to Imperial College as a Reader in 1948 — and these remarks are written from the vantage point of one of these — regarded holography as a laboratory curiosity. Yet, with hindsight, the passage is, surely, an entirely apt commentary on the invention of holography.

Often one finds that an inventive step follows very hard on the heels of another discovery, or some advance in technology which made it possible. Holography, however, was ready for birth at least half a century before the idea occurred to Gabor. Moreover, although the demonstrations in optics were difficult, there was no inherent reason why the principle should not have been demonstrated in acoustics — where, indeed, it has found application in recent years. By this criterion also, the invention of holography must be seen as an extraordinary stroke of brilliance.

In this period, Gabor also produced his pioneering contributions to what we now call communications theory — beginning with a remarkable paper published in the *Journal of the Institution of Electrical Engineers* in 1946. This work was inspired by the desire to gain a deeper understanding of the structure of information transmission; yet, included in the motivation there was, as always with his work, a thrust towards the applied, towards the inventive step. It led him to investigate means for transmission of information using 'band-width compression', a theme which remains an exciting area of research to this day.

When Gabor moved to Imperial College in 1948, he presented a remarkable and, at first, unfathomable phenomenon to his research students. He had little comprehension of the difficulty encountered by ordinary mortals in attempting to gain an appreciation of his aims in a particular research endeavour, or to follow a leaping thought line without the help of stepping stones. His lecture courses on electromagnetic theory, statistical physics, the plasma state, electron optics, seemed memorable but hardly capable of assimilation — at least, until the realisation dawned that they were not so much lectures as master classes. It was necessary to 'know' the subject before attending these occasions; but then the experience was enormously worthwhile — providing both the long historical view as insight in depth and generality. There must be many who still treasure the copious lecture notes typed at high speed by Gabor himself using an amazing two finger technique on a battered, ancient portable. There must be many who regret that these notes never found a more permanent expression in what would have amounted to a unique set of books; but research, invention and original thought was always the greater attraction and the more compelling master of his time.

There was no doubt amongst his students that Gabor could and should receive the Nobel Prize for something — we debated just what it might be. Nor was this a symptom of hero worship, of which we were largely innocent. We could assess the magnitude of the intellect but found it harder to discern its direction. We were also aware of a personality of great warmth yet of inherent shyness. Communication was not always easy. And the attempts to capture that personality, the highly charged, penetrating comments, the humour, the perfection and elegance of expression, though clothed in a Hungarian accent of some substantial depth, was the supreme task of those endowed with any ability of mimicry — though one doubts whether their skill will ever again be displayed.

Recognition outside his immediate group was slow to come. Gabor was a physicist who saw himself as a practical engineer — a reversal of the more usual aspiration for role changing. Not all physicists recognised this situation. I remember a seminar, perhaps around 1953, to an audience largely of physicists, where Gabor discussed the interpretation of discrete energy losses suffered by electrons when transmitted through thin metal films, in terms of plasmon excitation — an explanation which we now know to be essentially correct. The criticisms which he met at the time were fierce, and seemed to transcend the requirements of scientific debate — there seemed to be an element of a demarcation dispute.

By the early fifties, Gabor had completed his work on holography, made pioneering contributions to information theory, to electron optics, to electron-electromagnetic interactions and to plasma theory. Yet, he was still a Reader in the University and repeatedly failed to achieve election to the Royal Society. The omission was resented by his students and others who knew him well; it was deeply felt by Gabor himself. It was hard to comprehend at the time; it is no easier to do so in retrospect. Throughout this period, however, Gabor's creative work never faltered. Flat television tube research involving the most ingenious electron optical conceptions lived side by side with learning machines, with holographic microscopy and, a little later, with schemes for direct generation of electricity from heat using a plasma — a technique which echoed some of his work on gas discharge lamps of three decades earlier. Many of these schemes remain as fascinating concepts, devoid of practical implementation. But it would be unwise to write them off; holography had a gestation period of 15 years.

In 1956, Gabor was, at long last, elected a Fellow of the Royal Society and two years later became the Professor of Applied Electron Physics at Imperial College. His inaugural address marked a totally new direction in his publications and his thought, — to the socio-political problems faced by mankind as the direct consequence of advances in technology. The lecture, later published in the form of a most compelling contribution to *Encounter*, eventually formed the basis of a celebrated book, *Inventing the Future*. The trilemma facing mankind: war, excess population and leisure, is now revealed wisdom — part of the backcloth of our existence. It was not so when the book was first published in 1963. The approach taken in this book — an appraisal of the

enormous dangers, coupled with a guarded optimism that, with their recognition, the worst could be avoided — Gabor pursued and developed in a series of further publications. He became a founder member of the Club of Rome, and thereby became embroiled in the fierce debates which followed the publication of *Limits to Growth* by Forrester and Meadows. His stance was one of cheerful and total support for these authors — though a careful examination of his expressed opinions reveals that this support did not, in fact, rest on his assessment of the computer model calculations which caused such widespread alarm.

Just before *Inventing the Future*, it became clear that holography, transformed by the discovery of the laser, was turning into one of the most rapid growth topics in applied science. The range of applications appeared to grow month by month; holography was recognised as a principle of such generality tht it could touch many branches of physics, biology and engineering. Gabor, himself, contributed several inventions to this growing field. He lectured widely on the subject. Many will never forget a brilliant discourse at the Royal Institution which he gave in 1969. The recognition, so long denied, or belatedly bestowed, came in full flood. Honours of all kinds were showered upon him and, in 1972, the Nobel Prize.

There remained some good years. They were devoted to scientific work at the CBS Laboratories in the USA, to Imperial College and London, and to a villa in Italy. Gabor continued to contribute to what became his dominant and passionate concern — the adjustment of the human condition to the new world, which the explosive development in science and technology had wrought within his own lifetime and experience. Prophecy is the hardest of arts; scientists as a body are not notably more successful than others in its practice. Yet, if any doubt that there are some, a very few, who can penetrate that ultimate unknown at least some little distance, they should re-read *Inventing the Future* of 1963, or, perhaps, the Fawley Lecture of 1972, *The proper priorities of Science and Technology*.

Dennis Gabor married Marjorie, née Butler, in 1936, a marriage which brought great happiness and continuing support, in a life which knew both bitter disappointment as well as triumph and total fulfilment.

Eric A. Ash

Airey Neave

A GENERAL ELECTION is a deep parliamentary gulf dividing sharply one time from another. I have returned to the House of Commons not only to a new parliament and a new government but to unfamiliar faces that crowd the benches as solidly and confidently as did those whose places they have taken. But there is outstandingly one face absent from the chamber, one expected figure not again to be met in the long corridors. I refer to my friend Airey Neave, the victim of a cowardly political murder within the precincts of that same Palace of Westminster where we meet.

Leading figures in public life, the newspapers, radio and television have all said so much deservedly in tribute to Mr Neave, his life and work, that it might seem presumption on my part to add more. Nevertheless these columns give me an opportunity to enlarge a little on his considerable services to the Select Committee on Science and Technology of the House of Commons, for Airey Neave was a founder member of the committee from its establishment in 1967 until 1975 when he became opposition spokesman on Northern Ireland.

I was the first chairman of the select committee but in 1970 when the Conservative government of Mr Heath came to power, in accord with parliamentary practice, Airey Neave succeeded me for the parliamentary sessions of 1970-1974. Every chairman, I suppose, has his own style and Airey's was very much his own. In dealing with witnesses, especially those (and there are a few) who think that politicians cannot possibly have knowledge of anything except the suspect business of getting elected, he could be severe to near inquisitorial. Yet never for an instant did he go beyond the needs of the inquiry being conducted. As a good select committee chairman should, he saw his primary duty to parliament, not to governments or parties. I remember well how he gave a rising Conservative ministerial star caught out in a mistake a wigging that led to withdrawal and public apology. But to the general run of helpful and co-operative witnesses, enduring the unfamiliar ordeal of questioning in public, Airey was the soul of courtesy.

In the chair Airey Neave was vastly impressive to witnesses as he was to colleagues on the committee because of his detailed knowledge of the subject under consideration. His capacity for work was truly prodigious. Among the inquiries he handled either as chairman of the main committee or as chairman of a sub-committee, were population control, the Rothschild proposals and the computer industry.

But I suppose the inquiry that brings me closest to Airey Neave in memory was the one that the select committee carried out, through a sub-committee, into the choice to be made by Britain for the 'third generation' of nuclear reactors, the Magnox reactor being counted first generation and the advanced gas-cooled reactor second generation. This was during the time of the Heath government, when Mr Peter Walker was, as Secretary of State for Technology, the responsible minister.

The assumption had been that no firm decision would be taken on the choice to be made without a ministerial statement and the normal opportunity for parliamentary questioning. Then a long special article appeared in a leading Sunday newspaper by a science correspondent, to the effect that the Central Electricity Generating Board had made up its mind already and that American style pressurised water reactors were to be bought on a large scale for installation in the British electricity supply system, with the co-operation of our manufacturers and the apparent approval of the government.

Simple parliamentary questioning took us little further forward and Airey and I both agreed that this was just the kind of situation for which the select committee had been established.. After all, the British taxpayer had either spent or had guaranteed large sums of money in the past on the assumption that Britain had the most efficient and safest nuclear power arrangements in the world with the gas-cooled systems and now for parliament to be told that we had been wrong all the time took more than a little swallowing.

Because of his declared interest as a director of a plant manufacturer engaged in the nuclear field, Airey Neave felt he should not take the chairmanship of the inquiry and I occupied his place, though he served on the sub-committee. To a great extent it was the safety of the PWR in an emergency situation that took the attention of the inquiry and on this point critical evidence was received from Sir Alan Cottrell, then Chief Scientist to the government — evidence which had not been published before.

The conclusion of the select committee, reported to the House of Commons, was that the case for abandoning British reactor systems and adopting the American system could not be sustained by the evidence submitted and we advised caution over the PWR. Needless to say, some but not all parts of the nuclear technological establishment attacked the select committee for political meddling and worse. Nevertheless, a full day's debate in the Commons found members of parliament on both sides impressed by the committee's findings and Airey and I followed up the debate with a joint appearance on the national television network which engendered a large correspondence. Many of our correspondents were obviously impressed by the way in which a select committee of the Commons could, while supporting nuclear development in general, run up a danger flag about one particular proposed development. Who in the light of Harrisburg could to-day say we were wrong?

I spoke to Airey Neave last on the Thursday night before his death on the following day. We met by chance in the Commons lobby and discussed the future of the select committee on Science and Technology in the light of suggested procedural reforms for select committees in a new parliament. I did not know then I was never to see him again.

M

ICE AGES
Solving the Mystery

John Imbrie and Katherine Palmer Imbrie

In 1971 the National Science Foundation organised the CLIMAP project to study changes in the climate of the earth over the past 700,000 years. Out of their analytical work came an exciting by-product: confirmation of the correctness of one of the several theories about what causes ice ages to occur.

This book was written by one of the principal scientists of the CLIMAP group and his daughter, a writer. It presents the recent findings and puts them into perspective. It tells the story of ice ages: what they were like, why they occurred, and when the next one is due.

"It is satisfying that at last we have a work which brings us up to date on a scientific mystery whose solution will literally dictate the future of humanity."
Dr. Stephen H. Schneider, deputy head of the climate project of the National Center for Atmospheric Research.

FLOODS
A Geographical Perspective

Roy C. Ward
Focal Problems in Geography series

This study of major flood problems ranges from the hydrological causes of floods, and their prediction and routing, to a survey of man's response when confronted by serious flooding. Each of the world's major flood-areas is considered, and particular reference is made to floods as geomorphological agents.

October 1978 Hardcover £8.95 Paperback £3.95

MACMILLAN PRESS

Oxford University Press

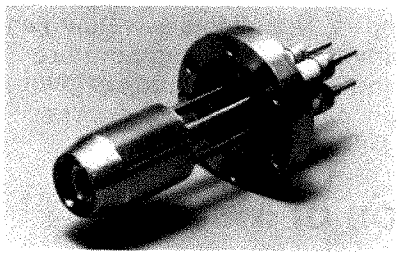
Soviet Science
Zhores A. Medvedev

In this short history of science in the Soviet Union, the emphasis is on the interaction between scientific and technological developments and the political objectives of the Soviet government. The book tells of the persecution and survival of the scientific community under different periods of political pressure, from the Revolution and its aftermath, through the purges of the late 1930s and the military control of the war years. £5.95

Materials for High-Temperature Use
M. F. Day

This Engineering Design Guide reviews the difficulties associated with the design of engineering components for use at elevated temperatures. The behaviour, relevant mechanical properties, and oxidation and corrosion resistance of materials suitable for use at temperatures up to 800 degrees Centigrade are discussed in relation to existing design codes. The effects of welding and the techniques employed with high-temperature materials are described, and information is given on corrosion-resistant coatings. Paper covers £2.75 *Engineering Design Guides 28*

The Selection of Materials
N. A. Waterman



This Guide provides a systematic approach to the selection of materials for engineering products. Analysis of the critical requirements of a product, identification of the possible materials, manufacturing routes, and procedure for optimum choice of material in terms of performance and cost are described. Paper covers £3.95
Engineering Design Guides 29

Electrostatics
A. W. Bright, R. P. Corbett, and J. F. Hughes

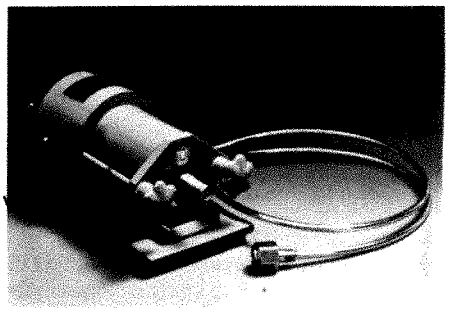
Modern electrostatics is widely used in the areas of environmental pollution control and manufacturing industry. In this Guide the two main branches of the subject, comprising industrial applications (including printing) and hazards, are discussed, while a further section outlines developments in electrostatic generators. The Guide concentrates on a practical approach to the subject rather than on the development of formulae. Paper covers £4.25
Engineering Design Guides 30

newly on the market

Gallium ion source. Dubilier Scientific. The Culham ion source and its control unit is a new system for producing ionised beams of high efficiency and purity within ultra high vacuum installations. Comprising a liquid metal gallium source, the DS 7800, and its control unit, the DC 10-100, the Culham system is easy both to install and to operate, and provides a stable source of gallium ions at currents ranging from 5 μA to 100 μA and at energies from 0.1 keV to 10 keV. The source consists basically of a heating unit, a reservoir for molten gallium, and an anode and cathode mounted on a standard 70-mm UHV flange. Gallium ions are emitted from a metal vapour plasma ball at the top of a jet of liquid gallium, the jet being anchored to a needle-shaped anode. The jet is formed by an intense electric field between the anode and cathode, at a threshold voltage of 4–5 kV. Once formed it is stable between currents of 5-100 μA.
Circle No. 84 on Reader Enquiry Card.

The Culham ion source

Flame photometer. Corning. The model 460 from Corning contains, in a single case, the basic flame photometer, a sampling and dilutor system, digital and printer readout, and a compressor. The instrument can be used to measure Na and K simultaneously from serum, plasma or urine, or alternatively Li. It automatically re-calibrates itself after every nine samples and has a self-monitoring system that identifies any problem — for example, should the gas supply run out an audible warning signal sounds, the instrument automatically cuts out, and an illuminated display on the front panel explains what has happened.
Circle No. 85 on Reader Enquiry Card.



Gas chromatography detector. Packard. The availability of a nitrogen/phosphorous-sensitive detector is announced by Packard. Test results show improved selectivity and sensitivity for molecules containing nitrogen and phosphorous. The detector's ability to analyse anti-depressants, anti-epileptic drugs, amino acids and residual pesticides is demonstrated.
Circle No. 86 on Reader Enquiry Card.

Selective analyser. Greiner. The Greiner selective analyser G-300 enables routine and emergency tests in a clinical chemistry laboratory to be performed. Out of a choice of 75 different methods covering electrolytes, metabolites, enzymes, immunochemistry and enzyme-immunoassays, up to 30 parameters can be selected. Also, the instrument's flexibility allows individual adaptation of tests to specific analytical necessities in certain laboratories.
Circle No. 87 on Reader Enquiry Card.

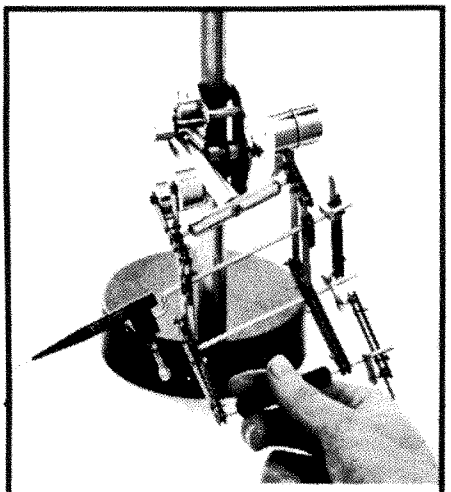
UV Detector for HPLC. Schoeffel have introduced a new low cost UV detector for HPLC. The model SF 740 multi-wavelength UV detector uses a deuterium lamp and can therefore perform absorption measurements at any wavelength between 200 and 380 nm without changing lamps. Quick-change filter cassettes isolate the wavelength of interest. Standard filters available from the company include 200, 215, 240, 254 and 280 nm with other wavelengths available on special order. The SF 740 also features an easily removed and cleaned flowcell with a small 10-μl volume. Nine calibrated absorbance ranges are push-button selectable. Noise in this single beam reference compensated detector is less than 1×10^4 AU.
Circle No. 88 on Reader Enquiry Card.

Technetium (EHIDA) agent. The Radiochemical Centre. The technetium (EHIDA) agent from the Radiochemical Centre is designed for hepatobiliary scintigraphy. It allows rapid extraction from blood by the parenchymal cells of the liver; rapid transit through the liver to the biliary system at high concentration; This agent has a 3–8-ml reconstitution volume, up to 5 patient doses per vial, and may be used up to 6 h after reconstitution (stored at room temperature). Kit shelf-life normally at least 17 weeks after despatch.
Circle No. 89 on Reader Enquiry Card.

Automatic leak detector. Edwards High Vacuum announces a new, very sensitive mass-spectrometer leak detector, the LT204. Developed from the LT104, the new unit combines the same ease of operation, fast warm-up and rapid cycle times with a very fine detectable leak rate of 2×10^{-12} mbar l s^{-1}, or 2×10^{-11} mbar l s^{-1} at full pumping speed. To accommodate the new, small leak rate, three extra ranges have been added to the unit, which now gives direct readout in mbar l s^{-1} over the range of 2×10^{-11} to 10^{-4} mbar l s^{-1}.
Circle No. 90 on Reader Enquiry Card.

The Technilab Frigimat

Dry-ice maker. Technilab. A ready source for small blocks of dry ice in the laboratory is now available from Technilab Instruments. The Frigimat dry-ice maker is connected to a CO_2 cylinder, and yields a solid 454 g block of dry ice in approximately 1 min. The unit is supplied complete, and ready for connection to a CO_2 cylinder. It produces a block of dry ice 8.6 cm in diameter and 11 cm long.
Circle No. 91 on Reader Enquiry Card.



Chemistry Kit. Wheaton Scientific announces a new chemistry kit featuring Wheaton Connections — unique 1-piece seals that let you screw components together in assemblies that cannot fall apart. Components in the Wheaton semi-micro kit feature screw threads for the Wheaton Connections. No clamps, grease or springs and hooks are needed to join the glassware. The kit is ideal for schools and universities. A 12-page brochure is available with complete information on the Wheaton semi-micro kit and an array of components and accessories using the Wheaton Connections.
Circle No. 92 on Reader Enquiry Card.

Refrigerated centrifuge. Burkard Scientific announce a new version of Koolspin, their table-top refrigerated centrifuge. Now the Koolspin range includes a large bowl version, taking up to 8 × 15 ml tubes in a swing-out rotor. This increase of bowl size has been achieved with little change in case size and overall weight. Bowl air temperature control remains at +10° to -10°C, and the speed range of this new version will be 0 - 10,000 r.p.m. Acceptable tube size range is 200 μl - 25 ml. These Koolspins all have a fully automatic lid-lock system that prevents the lid from being opened when the rotor is moving.
Circle No. 93 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

APPOINTMENTS VACANT

MEDICAL RESEARCH COUNCIL
Unit of Clinical Pharmacology
UNIVERSITY DEPARTMENT OF CLINICAL PHARMACOLOGY
Radcliffe Infirmary
Oxford OX2 6HE

Technician required for a research project concerned with cerebral arterial damage and platelet responses in cerebrovascular disease with emphasis on the role of prostaglandins.

Applicants should have HNC, degree or equivalent qualifications. Familiarity with bioassay and the separation of biologically active materials would be an advantage. Salary will be within the range £3,261 to £4,680.

Applications with the names of two referees should be sent to the Chief Technician at the above address by 20 August, 1979. 2763(A)

OVERSEAS DEVELOPMENT ADMINISTRATION and UNIVERSITY OF BRISTOL
Tsetse Research Laboratory
Langford
ENTOMOLOGIST

Applications are invited for a postdoctoral position to work for two years on the responses of tsetse flies to light of various wavelengths. Depending on the outcome of the laboratory work, there is a possibility of additional funds becoming available for a continuation of the work in Africa. Salary will be on the scale for University Research staff, £4,232 to £7,145 pa, according to age and experience. (Salary scale subject to revision on 1st October, 1979).

Applications, with a curriculum vitae and names of two referees, should be sent, before 15th September, 1979 to The Director, Tsetse Research Laboratory, Langford House, Langford, Bristol BS18 7DU. 2766(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BIOCHEMISTRY
TECHNICIANS GRADE 2B (TWO POSTS)

To assist groups studying:
a) The biosynthesis and metabolism of sterols in higher plants and algae.
b) Hormonal control of insect development.

Minimum qualifications ONC or equivalent relevant qualifications. The posts are tenable for 2½ years with possibility of renewal.

Salary within range of £2,757 to £3,138 p.a., according to qualifications and experience.

Application forms available from The Registrar, The University, P.O. Box 147, Liverpool, L69 3BX. Quote Ref: RV/722/N. 2744(A)

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
LABORATORY SCIENTIFIC OFFICER

Required in a research laboratory as technical assistant in a team with Professor Holborow investigating immunological aspects of rheumatic and other diseases. The vacancy is suitable for someone with laboratory experience who is interested in training in immunological techniques, including immunoflourescence and immunoenzyme methods.

Salary range (currently under review) £3,615 to £4,284 including London Weighting, according to qualifications.

Applications as soon as possible to Professor E.J. Holborow, Bone and Joint Research Unit, The London Hospital Medical College, Turner Street, London E1 2AD, quoting Reference No. BJRU/8/79. 2741(A)

MICROBIOLOGIST PhD

We are one of the largest chemical companies with worldwide research efforts. We have a position now available for a PhD in Microbiology, with at least 3 years experience in the field of antibiotic research. Successful candidate will be experienced in the isolation of antibiotic-producing micro-organisms with a strong background in strain selection, taxonomy and antibiotics fermentation. The position is responsible for leading a group of 6 assistants engaged in the search for new antibiotics and other microbial metabolites.

UNIVERSITY OF EDINBURGH
CHIEF MEDICAL LABORATORY SCIENTIFIC OFFICER

required for the Department of Bacteriology, University Medical School, Teviot Place, Applications are invited from suitably qualified persons for this post in the Hepatitis Reference Laboratry. Experience is Hepatitis diagnosis and research would be an advantage and wide experience in virological techniques, possibly including biochemical techniques, radio-immunoassay and electron-microscopy, essential. Salary on the scale £5,472 to £6,192 p.a. (under review). Ref: N291.

SENIOR MEDICAL LABORATORY SCIENTIFIC OFFICER

Required for the Immunology Section of the Department of Bacteriology, University Medical School, Teviot Place. Duties will include laboratory stewardship, preparation of teaching material and association with the research interests of the laboratory. Applicants either with Fellowship of the Institute of Medical Laboratory Sciences or a Post-Graduate Degree, should have experience in a range of immunological methods and some knowledge of microbiology and tissue culture procedures would be an advantage. Salary on the scale £4,347 to £5,769 p.a. (under review). Ref: N 293.

Applications can be obtained from the Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS. Telephone 031-556-2930. 2791(A)

THE UNIVERSITY OF BIRMINGHAM
Faculty of Medicine and Dentistry
DEPARTMENT OF IMMUNOLOGY
POST DOCTORAL RESEARCH FELLOW

A post doctoral Research Fellow is required to join a group, headed by Dr G. Brown, studying antigens of myeloid cells. This work involves the extensive use and production of monoclonal antibodies to study the differentiation of the granulocyte and monocyte series and to assess changes associated with leukaemic transformation. This work is being carried out as a combined project with Dr F. Kourilsky's group in the Centre d'Immunologie at Marseille.

The post is funded by the Leukaemia Research Fund for a three year period and the salary is within the Research Range 1A (£4,333 to £7,521 with superannuation benefits). The maximum starting salary will be £5,488.

Applicants should have a postgraduate degree and experience in tissue culture and the cloning of cells.

Persons interested in the post should contact Professor I.C.M. MacLennan's secretary, Department of Immunology, the Medical School, Vincent Drive, Birmingham B15 2TJ.

Applications, three copies, including curriculum vitae and the names of two referees to the Assistant Registrar, Faculty of Medicine, University of Birmingham, Birmingham B15 2TJ by 30th August 1979. Please quote ref: RA/IMM/49. 2739(A)

Organon Research & Development

Organon Research & Development laboratories function as an international and multidisciplinary scientific organisation of about 650 members of whom 500 are located at Oss in The Netherlands. They work on a wide ranging programme aimed at the development of new drugs and maintain close contacts with scientific institutions all over the world.

In our General Pharmacological Research & Development Laboratories a position is available for a

cardiovascular pharmacologist

or a

cardiovascular physiologist

Following an introduction to all activities of this department the successful candidate will head one of our teams investigating the effects of drugs on the circulation. The appointee must be a creative research worker capable of applying modern methods in microcirculation and of acting as a liaison with other groups, particularly the data processing unit.

Remuneration will be commensurate with the experience of the candidate and the responsibilities of this important position.

Applications or requests for further information should be directed to the Personnel Department, Organon International bv, Kloosterstraat 6, 5349 AB Oss, The Netherlands under no. D79-01

Organon

Organon International bv

100/12 W264(A)

UNIVERSITY OF SYDNEY

CHAIR OF PHYSICS

Applications are invited for a newly established Chair of Physics. The School of Physics has at present major research activities in the fields of optical astronomy, radio astronomy, plasma physics, theoretical physics and cosmic ray physics. The University is seeking a suitably qualified person, preferably with a background in solid state physics, surface physics or materials science and with an interest in solar energy conversion. It is expected that an expanded activity in solar energy conversion will be carried out in close collaboration with the Faculty of Engineering where there are a number of joint solar energy projects with the School of Physics.

Salary: $A34,119 p.a.

A Statement of Conditions of Appointment and information for candidates may be obtained from The Registrar, University of Sydney, NSW 2006, Australia, with whom applications close on 30 September 1979. Information is also available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

2724(A)

UNIVERSITY OF LONDON

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

LECTURESHIP IN CELL BIOLOGY

The position is in the Department of Biochemistry but the person appointed will contribute to the teaching of cell biology in the division of life sciences. Applications are invited from candidates experienced in electron microscopy. The Department has strong interests in Neurobiology, and excellent facilities are available for transmission, scanning, stem/electron probe and freeze-fracture electron microscopy and for autoradiography.

Salary will be at the appropriate point on the Lecturer scale (£4,232 to £8,452 to be reviewed) plus £502 per annum London Allowance. It is intended to make this appointment during the academic year 1979-80.

Applications including a curriculum vitae, a short summary of research experience and the names of three persons to whom requests may be sent for a reference, should be sent by October 31st, 1979, addressed to Professor E. A. Barnard, Department of Biochemistry, ICST, London SW7 2AZ.

2757(A)

UNIVERSITY COLLEGE OF NORTH WALES

Bangor

DEMONSTRATOR

DEPARTMENT OF MARINE BIOLOGY

Applications are invited for the above post in the College's Department of Marine Biology, to commence on 1st October, 1979, or as soon as possible thereafter. Applicants should be graduates of chemistry, biochemistry or microbiology. Previous experience in aquatic chemistry or microbiology would be an advantage but is not essential.

The appointment will be within the range £3,689 to £4,232 per annum, and will be for one year in the first instance, with the possibility of extension for a further two years.

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG. Informal enquiries can be made to Dr C P Spencer (Bangor 712641, Extension 6642). Closing date for applications is 13th August, 1979.

2755(A)

UNIVERSITY OF EDINBURGH

Mitochondrial Genome Expression

POSTDOCTORAL RESEARCH FELLOW

required to join a group led by Dr C J Leaver working on mitochondrial genome expression during plant development. Previous experience in the field of mitochondrial biogenesis or function together with an interest in membrane protein isolation and purification would be an advantage but not a necessity. The successful candidate will also be required to use various techniques involved in nucleic acid isolation and *in vitro* translation already in use in the laboratory.

This post is supported by the SRC and is available from 1st October 1979 for three years but a suitable applicant may start at a later date. Salary on the 1A Scale for research staff, plus USS benefits.

Applications with curriculum vitae and naming two referees should be sent to Dr C J Leaver, Department of Botany, The King's Buildings, Mayfield Road, Edinburgh EH9 3JH, Scotland, as soon as possible. Please quote reference 5037.

2734(A)

THE INTERNATIONAL CENTRE OF INSECT PHYSIOLOGY AND ECOLOGY
Nairobi, Kenya

RESEARCH SCIENTIST (TERMITE ECOLOGY) (Re-advertised)
REF: SCI/78/10

Applications are invited from suitably qualified persons for the above positions.

Qualifications:
Ph.D. with 5 or more years postdoctoral research experience in the field of Insect Ecology. Previous acquaintance with social insects, particularly Termites will be of advantage, but high quality research for Ph.D and evidence of excellence since postdoctoral experience will be a critical criterion.

Responsibilities:
The successful candidate will carry out research in Termite Ecology, particularly the study of termite foraging activity in competition with other animals, termite population density and their role in the semi-arid savannah environment.

He will be expected to work in collaboration with the large research staff in other aspects of termite ecology and in termite physiology.

Salary:
Negotiable and includes attractive benefits.

Closing Date:
Applications giving detailed information on general education, professional qualifications, experience, marital status, age, present terms of employment (including salary), names and addresses of 4 referees (including one personal), and photocopies of relevant certificates and diplomas should be addressed to:

Administrative Manager,
ICIPE Research Centre,
P.O. Box 30772, NAIROBI.

to reach him as soon as possible.

W262(A)

THE INTERNATIONAL CENTRE OF INSECT PHYSIOLOGY AND ECOLOGY
Nairobi, Kenya

Applications are invited from suitably qualified candidates for the following position:

RESEARCH SCIENTIST (SENSORY PHYSIOLOGY RESEARCH UNIT)
REF: SCI/79/7

Qualifications:

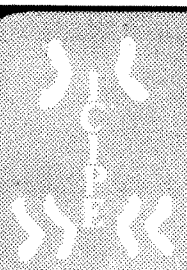
At least a Ph. D., degree in Zoology, Entomology or Physiology. Preference will be given to candidates with a broad background in Chemistry, Physics and General Physiology.

Suitable candidates should have considerable practical experience in sensory electrophysiological techniques, preferably at single-cell level; quantitative and qualitative behaviour studies, including the bioassay of natural products. Experience in histology, transmission and scanning electron microscopy would be an asset.

Responsibilities:

The successful candidate will be required to work in the field of sensory physiology and behaviour of insects and ticks restricted to one or several of the ICIPE target organisms: tsetse flies, termites, ticks, armyworm moths, mosquitoes, stem-borers and shoot-flies. The project work will be defined in greater detail with target-oriented research programme teams. Willingness to collaborate with colleagues in other disciplines is of first order importance. In spite of the relative adequate availability of research equipment at the Centre, the situation calls for innovative ability for improvisation.

Salary:



Negotiable and include attractive benefits.

Closing date:
Applications giving detailed information on general education, professional qualifications, experience, marital status, age, present terms of employement (including salary) names and addresses of four referees (including one personal), and photostat copies of relevant certificates and diplomas should be addressed to:

Administrative Manager
I.C.I.P.E.
P.O. BOX 30772,
NAIROBI, KENYA.

to reach him as soon as possible.

W262(A)

THE INTERNATIONAL CENTRE OF INSECT PHYSIOLOGY AND ECOLOGY

Nairobi, Kenya

Applications are invited from suitably qualified candidates for the following positions:

RESEARCH SCIENTIST (MEDICAL VECTOR RESEARCH PROGRAMME)

REF: SCI/79/1

Qualifications:

Ph. D., with five or more years of postdoctoral experience in biological and physiological sciences and demonstrable experience in research on mosquito ecology. Evidence for excellence since postdoctoral training will be a distinct advantage.

Responsibilities:

The successful candidate will work on malaria epidemiology in Tropical Africa with special interest on immunology and culture parasites. This new project will be linked with one on bancroftien filariosis epidemiology.

SENIOR RESEARCH SCIENTIST (BASES OF PLANT RESISTANCE TO INSECT ATTACK)

REF: SCI/79/4

Qualifications:

Ph. D., with five or more years postdoctoral research experience. High quality research for Ph. D., and envidence for excellence since doctorate degree will be a critical criterion. If an internationally recognised first-class senior scientist with previous experience in tropical environment applies, he may be considered for the leadership of the research programme.

Responsibilities:

The successful candidate will carry out research in planthost/insect relations, in some instances, including mass-rearing techniques and screening for resistance. The long-term objective of the research programme is to investigate thoroughly and establish the bases of plant resistance to insect attack. The research effort will specifically cover cereal stem-borers, legume pod-borers, and maize streak virus disease, at least, initially.

SENIOR RESEARCH SCIENTIST (CROP BORERS PROGRAMME)

REF: SCI/79/5

Qualifications:

Ph. D., with five or more years of practical experiance in the field of borers research. High quality research for Ph. D., and evidence for excellence since doctorate degree will be a critical criterion. If a first-class senior scientist of international status, with relevant technical expertise and a wide experience in tropical environment applies, he may be considered for the leadership of the research programme.

Responsibilities:

The successful candidate will carry out research in the field of crop borers, whether basic or applied. If appointed a leader, he will formulate the programme in collaboration with the ICIPE Director, supervise the research activities of the staff in the programme and handle some administrative and accounting problems.

RESEARCH SCIENTIST OR SENIOR RESEARCH SCIENTIST (FINE STRUCTURE RESEARCH UNIT)

REF: SCI/79/6

Qualifications:

Ph. D., in a biological science with considerable training and technical expertise in electron microscopical and associated techniques.

Responsibilities:

The successful candidate will be responsible for the organisation of the work of the Fine Structure Research Unit.He will also be able to pursue his own research in insect fine structure, including cytochemistry and autoradiography, and to assist other scientists with their work involving electron microscope techniques. The position is a very responsible one and requires a senior mature and experienced electron microscopist with wide organisational ability and enormous technical expertise.

Salary:

Negotiable in respect of all posts and includes attractive benefits.

Closing date:

Applications giving detailed information on general education, professional qualifications, experience, marital status, age, present terms of employment (including salary), names and addresses of four referees (including one personal referee) and photocopies of relevant certificates and diplomas should be sent to:

Administrative Manager,
ICIPE Research Centre,
P. O. BOX 30772,
NAIROBI.
Kenya.

to reach him as soon as possible.

Chemists

Two vacancies have arisen at our Welwyn Garden City site for Chemists, male or female. We offer excellent working conditions in modern well-equipped laboratories. The salary paid will be commensurate with experience and additional benefits include a Christmas Award, contributory pension scheme, free BUPA membership and a subsidised restaurant.

Organic Chemist -Research

Applications are invited from those with GRIC or BSc in Chemistry, this post is not suitable for someone with a PhD qualification. Research experience in the pharmaceutical industry would be an advantage but not essential. The chemist would assist a senior chemist in our Chemistry Department in the design and investigation of new procedures used in the synthesis of a natural product of chemotherapeutic importance.
Reference RC55 - Mrs. Clewley.

Quality Control Chemist

Applications are invited from those with an HNC or BSc in Chemistry for work on a range of analytical instrumental techniques, particularly the GIC analysis of pharmaceutical raw materials and products. This post would be suitable for a newly qualified graduate or someone who may also have had some experience of instrumental techniques.

Reference QC/ACJ - Mrs. Judge.

For further information and an application form, please telephone or write to the Personnel Department quoting the appropriate reference, Roche Products Limited, PO Box No 8, Welwyn Garden City, Hertfordshire, AL7 3AY telephone Welwyn Garden 28128.

ROCHE

2762(A)

FORSCHUNGSINSTITUT BORSTEL — FEDERAL REPUBLIC OF GERMANY

APPOINTMENT OF DIRECTORS

After retirement of the former director, there is a vacancy for the management of the Forschungsinstitut Borstel, (Institute for Experimental Biology and Medicine (district Bad Segeberg, situated at abt. 50 km distance from Lübeck, Kiel and Hamburg) which in future shall be made up of a board of directors consisting of 3 scientists.

The scientific orientation of the institute shall be concentrated on the research of diseases the clinical phenomena of which are accessible to medical-theoretical, experimental and scientific analysis. Priority will be given to infectious and related diseases the course of which is largely influenced by immunologic factors. This implies close collaboration of medical and scientific disciplines. The members of the board of directors shall represent the following scientific fields:

1. Clinical Medicine
2. Theoretical Medicine
3. Biosciences

The directors will be appointed professors for a lifetime (C 4), vizt. the medical fields at the Christian-Albrechts-University of kiel, and the bioscientific field at the Medical School (Medizinische Hochschule) of Lübeck.

The Forschungsinstitut Borstel includes a 180-bed hospital as well as medical-theoretical and scientific laboratories in which 38 scientists and 67 technical assistants are working at present. A total of abt. 400 people are employed at the institute. An additional laboratory with an effective area of 3.800 sqm will be built in 1980.

Applications, including curriculum vitae, list of publications and references should be sent by September 30, 1979 to the Vorsitzenden des Verwaltungsausschusses des Forschungsinstitutes Borstel, Ltd. Ministerilarat, Dr von Scheliha, 2300 Kiel, Düsternbrooker Weg 64-68
Der Kurator, Dr Helmut Lemke, Landtagspräsident.

W269(A)

UNIVERSITY OF NATAL
DEPARTMENT OF PHYSICS
Durban
PLASMA PHYSICIST

Postdoctoral Research Fellowship available October 1979 for at least one year, for experimental research in plasma waves and beam-plasma interactions. Salary range R8,100 to R11,200 p.a., plus travel allowance each way. Recent postdoc or sabbatical visitor suitable.

Send application, resumé and three referees' reports by September 1st quoting reference ADVD38/79 to Prof. M. A. Hellberg, Plasma Physics Research Institute, University of Natal, Durban, South Africa. W265(A)

UNIVERSITY OF BRISTOL

CHAIR IN PHYSIOLOGY

The University invites applications for appointment to the Chair in Physiology which becomes vacant on the appointment of Professor T.J. Biscoe to the Jodrell Chair of Physiology at University College, London. The appointment will carry with it Headship of the Department for a five year period in the first instance.

A clinical qualification is desirable but not essential. Candidates are invited to submit applications, including the names of three referees, not later than 12th October, 1979, to the Registrar and Secretary of the University, Senate House, Bristol, BS8 1TH, from whom further particulars may be obtained. 2782(A)

ST THOMAS'S HOSPITAL
MEDICAL SCHOOL
(University of London)
LONDON SE1 7EH
RESEARCH POST LEADING TO PhD

Physiologist or Biochemist with good first degree to study placental transfer and fetal metabolism.

Applications to Professor M Young, Department of Gynaecology. 2730(A)

KING'S COLLEGE LONDON
DEPARTMENT OF BIOPHYSICS
RESEARCH TECHNICIAN

Applications are invited for the post of Technician to work on Wellcome Trust supported research on the mechanism and control of chromatin transcription. Experience in sub-cellular fractionation techniques, protein and nucleic acid biochemistry and restriction endonuclease mapping would provide useful background.

The appointment would be for one year in the first instance starting 1 September (or sooner). Salary on scale £3,455 pa to £3,860 pa or £3,998 pa to £4,580 pa (inclusive) according to qualifications and experience.

Applications with curriculum vitae and the names of two referees should be sent to Dr J Allen (Ref: 217825/N), Department of Biophysics, King's College London, 26-29 Drury Lane, London WC2B 5RL. 2666(A)

With the escalating price of crude oil, its time to focus on the coal-to-oil technology of tomorrow

73' 75' 77' 79'

Stimulating opportunities for Chemical, Mechanical and Electrical Engineers on a permanent or contract basis in South Africa

Sasol Limited has the only commercial proven oil from coal plants in the world. In addition to petrol, diesel and industrial gas, a variety of petrochemical products and raw materials are produced and with the exporting of waxes, kogasins and alcohols to all parts of the world Sasol are earning valuable foreign currency for the country.

The Company was founded in the early fifties with the first plant situated in the northern part of the Orange Free State – some 50 miles south of Johannesburg – where a vast coalfield exists close to the Vaal River and the concentrated marketing areas. The second plant which is now being constructed on a site approximately 80 miles east of Johannesburg, will be considerably larger than the first plant in production capacity and will be commissioned early in 1980. A start has already been made with a third plant in the vicinity of the nearly completed second plant, at a cost of approximately £2 000 million. This brings the total cost of Sasol II and III to more than £3 300 million.

The successful applicants will be based in Sasolburg and Secunda.

Chemical Engineers

Applicants are required at all levels of seniority and should have a B.Sc. (Chemical Engineering) or equivalent qualification, preferably with experience in the petrochemical or refining industry. Successful candidates will have the opportunity of combining their engineering skills with creative ability to contribute to the effective functioning of the production process. Responsibilities will include the development of new processes, process design and project evaluation, the improvement of existing processes and the solving of process problems. Production orientated men will be responsible for the optimisation of the operation of chemical plants under their control.

Mechanical Engineers

Applicants are required at all levels of seniority with a B.Sc. (Mechanical Engineering) or equivalent qualification for the evaluation and optimisation of design studies for process equipment, high and low temperature systems as well as for static and rotary equipment. They will also be closely involved in an extensive range of projected and construction work. Those seeking the challenge and demand of maintenance or production work take full responsibility and authority for the specific function in an area of the Sasol plants.

Electrical Engineers

Applicants with a B.Sc. (Electrical Engineering) or equivalent qualification will be appointed either as area engineers (maintenance) or as project engineers. The area engineer will be responsible for all maintenance and switching in an area of the factory. He must ensure continuity of electrical supply, control budgets and a personnel of about 100 men as well as handling technical and administrative work.

Electrical project engineers, with at least 5–10 years experience of project and construction work are also needed.

These positions are based at Sasol II in Secunda.

Working at Sasolburg or Secunda offers . . .

* Residential locations where the most modern planning methods were employed in the development of the towns.
* Established and active multilingual communities with many schools, churches, clubs and cultural societies.
* Excellent recreational facilities which cater for virtually every sporting activity including nearby golf and sailing.
* The benefits of South Africa's pleasant climate and reasonable costs of living.

. . . with these benefits

* Assistance with travelling expenses to South Africa.
* A settlement allowance of up to £750 plus £55 per child.
* Financial assistance with the transportation of personal effects.
* Pension and medical fund and Group Life Assurance.
* Leave bonus of 8,3% of annual salary.
* 30 days annual leave and long leave after six years' service.
* Company housing plus 100% home purchase schemes.

If you have the talents we are looking for and the ability to use them there will be room for you to become a member of our permanent staff or you could join the Company on a contract basis. Interviews will be conducted in the U.K.

Please send a detailed curriculum vitae to Mr D. D. Rogers, 14a Cross Street, Reading, Berks. *quoting Ref. SS/6*

SASOL

2738(A)

BIOGEN S.A.

a young company engaged in basic and applied research in the field of molecular biology and microbiology, and with the objective of utilizing the potential of genetic engineering for the production of substances of commercial and medical interest in such areas as health care, agriculture and energy, is inviting applications from

SENIOR AND JUNIOR SCIENTISTS

with experience in molecular biology, nucleic acid biochemistry and microbiology,

for its **Research Laboratory in Geneva,**

Switzerland.

Excellent working conditions, in close contact with leading scientists from Europe and the US.

Salary scale: Group Leaders = SFr 60-85,000, Research Associates = SFr 35-55,000.

Applicants with real interest in both basic research and its applications should send their curriculum vitae (with a description of previous experience and a list of publications) to BIOGEN Laboratory, 3 Route de Troinex, 1227 Geneva, Switzerland. W248(A)

ASSISTANT SCIENTIFIC SECRETARY

Cancer Research Campaign

(British Empire Cancer Campaign for Research)

Due to the growth in both the extent and scope of its scientific activities the Cancer Research Campaign, one of the largest medical charities with an annual turnover in excess of £7 million, is expanding its Scientific Department and requires an Assistant Scientific Secretary.

The Scientific Department is responsible for the administration of the Campaign's scientific (as distinct from fund-raising) endeavours and the Assistant Scientific Secretary will help the Scientific Secretary and his staff in most aspects of their work, particularly in the processing of grant applications and the subsequent administration of those that are successful: at present the Campaign is supporting over 450 projects in 80 centres. A capable and enthusiastic individual will eventually have the opportunity to undertake most facets of the administration of scientific research.

The successful candidate is likely to be aged between 28-38 with some experience of biomedical research at a postdoctoral level and with a knowledge of science and medicine in the broadest terms, as well as an interest in a career in scientific administration. The appointment will be at the level of Senior Scientific Officer with a salary scale (currently under review) of £5,678 to £7,422 (with superannuation provision), and subsequent to satisfactory completion of a two-year probationary period can be permanent.

Applications by letter, accompanied by a curriculum vitae and the names of three referees, should be sent *marked "Personal"* and not later than 14 September 1979 to:-

The Administrative Officer
Cancer Research Campaign
2 Carlton House Terrace,
London SW1Y 5AR Tel 01-930 8972

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF ZOOLOGY

Applications are invited from men and women for an

SRC RESEARCH ASSISTANT (Range IB)

to work with Dr D.E. Kime on androgen biosynthesis and reproductive development in teleost fish. Tenable three years from 1 October 1979.

Initial salary £3,775 per annum (under review). Applications, with names of two referees to the Registrar and Secretary, the University, Sheffield S10 2TN by 17 August 1979.

Quote ref: R 348/G. 2753(A)

SCIENTIFIC OFFICER

BLOOD GROUP REFERENCE LABORATORY

A graduate is sought for research and development of new techniques relating to the standardisation of reagents (including albumin and enzymes) used in blood group serology. Some experience in protein chemistry or immunochemistry desirable.

Applications in writing with details of experience and the names of two referees to Miss K. Lomas, Blood Group Reference Laboratory, Gatliff Road, off Ebury Bridge Road, London SW1W 8QJ

2714(A)

UNIVERSITY OF SURREY

DEPARTMENT OF METALLURGY & MATERIALS TECHNOLOGY

RESEARCH STAFF

We have several vacancies for research staff to work on projects concerned with the mechanical properties of advanced fibre-composite materials. This is an opportunity to join an active and successful team working in well equipped laboratories and supported by Government and Industry. In appropriate cases consideration would be given for registration for a higher degree on a part time basis.

The posts vacant are:

RESEARCH OFFICER

Qualifications: BSc or equivalent in appropriate science or engineering discipline and good experimental aptitude. Salary from £3,689 according to qualifications and experience.

Note: A postdoctoral candidate might be considered for the post.

JUNIOR RESEARCH OFFICERS

Qualifications: Science A levels or equivalent. Salary from £1,722. These posts might suit a candidate who wishes to work for a year between school and university. In both cases appointments would be for 1 year with a possibility of extension to 2 or 3 years.

RESEARCH STUDENTSHIPS

We also have available an SRC CASE studentship in association with ICI Plastics Division for work on Toughness and Strength of Fibre-Filled Thermoplastics.

Applications which should include details of academic and industrial experience and the names of two referees should be submitted as soon as possible to: Mr M G Bader, University of Surrey, Department of Metallurgy & Materials Technology, Guildford, Surrey GU2 5XH. Tel: (0483) 71281 Ext. 895/623.

seeks candidates for a position in

PLANETARY SCIENCE

with emphasis on planetary surfaces or planetary atmospheres, and or observational programs using space-craft Appointment preferable at the assistant professor level.

Please contact Dr B. Kamb, Chairman Division of Geological and Planetary Sciences, California Institute of Technology, Pasadena, California 91125 giving résumé, bibliography, and research interests. An equal opportunity employer

W268(A)

UNIVERSITY OF THE WITWATERSRAND, JOHANNESBURG

DEPARTMENT OF PHYSICS

LECTURER

The successful applicant is expected to participate in the auxiliary teaching of the department and in its research which is done both experimentally and theoretically in the main areas of nuclear and solid state physics (some preference will be given to an experimental solid state physicist). Duties are to be assumed on a date to be negotiated.

Salary will be in the range R8 100 — R13 200 per annum. (£1 = R1.89 approx).

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and to the above post are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged by 20th August 1979. 2725(A)

OXFORD UNIVERSITY

PHYSICAL CHEMICAL LABORATORY

APPOINTMENT OF POST DOCTORAL RESEARCH ASSISTANT

Applications are invited from chemists or physicists to work on the laser diode, infrared spectroscopy of weakly bound van der Waals complexes. Applicants should have some experience either of high resolution spectroscopy or of working with lasers.

The appointment is for 2 years in Research Support grade 1A, with membership of U.S.S. Starting salary is up to £4,776.

Applications with curriculum vitae and the names of two referees should be sent as soon as possible to Dr B.J. Howard, Physical Chemistry Laboratory, South Parks Road, Oxford OX1 3QZ. 2777(A)

UNIVERSITY OF OXFORD

Departments of Pharmacology and Physical Chemistry

POSTDOCTORAL RESEARCH ASSOCIATE IN HIGH PRESSURE PHYSIOLOGY AND PHARMACOLOGY

A postdoctoral position is available for research related to diving and the effects of high pressure on man and animals, in an interdisciplinary research team conducted by Prof. Sir William Paton and Dr E B Smith. A number of lines of research are being actively pursued, ranging from physical chemistry to human physiology. The successful candidate could work in any of these areas, although preference may be given to those interested in neuropharmacological approaches.

Applications, including statements of research experience and publications, with the names of two referees, should be sent as soon as possible to Prof Sir William Paton, Department of Pharmacology, South Parks Road, Oxford OX1 3QT. It is hoped to make an early appointment to enable the successful candidate to take up the post by 1 October 1979, although this need not rule out applicants wishing to start later. 2672(A)

Microbial Geneticist

Shell Research Limited have a vacancy in the Fermentation and Microbiology Division of their Sittingbourne Research Centre for a Microbial Geneticist.

We are looking for a young graduate, preferably with some postgraduate experience who will be interested in the challenge of contributing to our substantial research programmes in biotechnology – for example biocatalysis, fermentation processes and biopolymers. Appropriate technical assistance will be available.

We offer a competitive salary and a range of excellent benefits including pension, flexible working hour system, staff restaurant and a recreational club. Please write or telephone for an application form to:

Shell Research Limited, Recruitment Division (N1), PNEL/11, Shell Centre, London SE1 7NA. Telephone: 01-934 2948.

Shell

2790(A)

UNIVERSITY OF NATAL

DEPARTMENT OF BIOCHEMISTRY

PIETERMARITZBURG

Applications are invited from suitably qualified persons regardless of sex, religion, race, colour or national origin, for appointment to the posts of

LECTURER (Ref. PMB 44/79) and SENIOR LECTURER (Ref. PMB 45/79)

Incumbents will be required to take up their duties on 1 January 1980, or as soon as possible thereafter.

The salaries will be in the range: Lecturer R8,100 to R13,200 pa. Senior Lecturer R11,400 to R15,600 pa.

The commencing salary will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus is payable, subject to Treasury regulations.

Application forms, further particulars of the posts and information on pension, medical aid, group insurance, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, PO Box 375, Pietermaritzburg, 3200, South Africa, with whom applications, on the prescribed form, must be lodged not later than 30 September 1979, quoting the relevant reference number. W266(A)

UNIVERSITY COLLEGE CORK

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH IN BIOCHEMISTRY

Applications are invited for two postdoctoral positions supported by grants from the National Board for Science and Technology. Applicants should have recently obtained, or expect to obtain in the near future, the PhD degree in biochemistry or chemistry. The projects are as follows:

1. Studies on the structures and activities of lipases from milk. The research programme will be under the joint direction of Professor S. Doonan, Department of Biochemistry and Professor P.F. Fox, Department of Dairy and Food Chemistry. The successful applicant will be based in the Department of Biochemistry which has extensive facilities for structural studies of proteins.
2. Studies in purine metabolism in muscle with particular reference to meat production. Some experience in the areas of purine metabolism and/or high performance liquid chromatography would be advantageous, but not essential. Good facilities are available for the isolation and quantitation of purines in tissues.

The appointments are for one year in the first instance with the possibility of extension for one or two further years. The initial salary is £3,837 (under review).

Applications, including a curriculum vitae and the names of two referees should be sent to arrive on or before *27th August, 1979* to Professor Shawn Doonan, Department of Biochemistry, University College, Lee Maltings, Prospect Row, Cork. 2778(A)

Wellcome

The Wellcome Research Laboratories Beckenham

Department of Parasitology

From £5,900

An opportunity has arisen in the research group studying malaria immunity and chemotherapy. The work involves department of methods of cultivation of malaria parasites.

Candidates should have post-doctoral experience in cell culture techniques and previous experience in malaria or other protozoan cell culture would be an advantage.

This appointment will be for a period of three years in the first instance.

The Wellcome Research Laboratories are situated in pleasant parkland surroundings, within easy reach of Central London. Excellent conditions of employment include subsidised canteen, pension scheme, 4 weeks' holiday and sports and social facilities.

For an application form, please write to the Personnel Manager, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS, giving brief details of background and experience. 2795(A)

1979

Southampton THE UNIVERSITY

DEPARTMENT OF BIOLOGY

A RESEARCH ASSISTANT

is required from 1 October to work with Dr C E Bennett on a SRC project to study the secretory products of the common liver fluke (*Fasciola hepatica*) and its avoidance of the host immune response.

Applicants should have a good honours degree in a biological science and have some background of parasitology or immunology. A knowledge of iso-electric focussing and of *in vitro* culture would be an advantage. Where appropriate the assistant may be permitted to register for a higher degree.

The appointment will be for three years at a starting salary of £3,775 per annum with annual increments and USS arrangements.

Applications with details of education, experience and the names of two referees should be sent to Mrs E C P Sears, Staffing Section, The University, Southampton SO9 5NH, quoting reference 1503/R/N. 2774(A)

ISRAEL

SENIOR PHYSIOLOGIST

Faculty of Health Sciences in Beer-Sheva requires a Senior Scientist to be responsible for the teaching and research in physiology in a recently established Medical School and a School of Allied Health Professions. Challenging position offering progressive Faculty with innovative curriculum.

Write enclosing CV and references to Dean, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel. W273(A)

POSTDOCTORAL POSITION to study luminescence of DNA and related compounds. Excitation is produced by bombardment with ultraviolet photons, X-rays, and high energy heavy-ions. Experience in luminescence spectroscopy of biological materials and with lasers and microprocessors is desirable. Deadline for applications is September 20, 1979. Send curriculum vitae and names of three references to: Dr Malcolm Daniels, Chemistry Department, Oregon State University, Corvallis, OR 97331. Oregon State University is an Equal Opportunity/ Affirmative Action employer and complies with Section 504 of the Rehabilitation Act of 1973. W263(A)

UNIVERSITY OF OXFORD

Sir William Dunn School of Pathology

RESEARCH ASSISTANT

Grade 1A

Salary £4,232 to £7,145

Applications are invited for a Research Assistant supported by the Cancer Research Campaign, to assist with research into the biochemical mechanisms of virus growth. Experience with mammalian tissue culture would be an advantage. Applicants should possess a degree or equivalent qualification.

Applications, in writing, together with the names and addresses of two referees, to the Administrator, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE. 2643(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF BIOCHEMISTRY

Applications are invited from biochemists or microbiologists for the post of

S.R.C. POSTDOCTORAL RESEARCH ASSISTANT

to study the electron transport chains of bacteria which obtain energy for growth from the oxidation of ammonia (e.g. Nitrosomonas). Previous experience in microbiology is desirable. The appointment is for three years with a salary up to the rate of £4,776 per annum. (Scale subject to revision with effect from 1st October, 1979).

Applications, including a brief curriculum vitae and the names of two referees should be sent by 17th August, 1979. to Dr P.M. Wood, Department of Biochemistry, Medical School, University of Bristol, University Walk, Bristol. BS8 1TD. 2747(A)

LIVERPOOL POLYTECHNIC
Department of Biology

RESEARCH ASSISTANT

To investigate the characterisation of Tipula Polyhedrosis Virus.

Applications are invited for a Local Authority Research Assistantship in the Department of Biology. The appointment is for two years in the first instance, the candidate being required to register for a research degree of the Council for National Academic Awards (MPhil/PhD). Subject to successful registration for PhD or transfer from MPhil by CNAA the appointment may be renewed for a third year.

Applicants should hold or expect to obtain a first or upper second class honours degree in an appropriate biological subject. Letters of application, together with a curriculum vitae and the names and addresses of two referees, should be sent to:

Dr J B Carter, Department of Biology, Liverpool Polytechnic, Byrom Street, Liverpool L3 3AF, from whom further details on the research topic and conditions of service may be obtained. 2764(A)

GUY'S HOSPITAL MEDICAL AND DENTAL SCHOOLS

RESEARCH ASSISTANT
(Biochemist/Immunologist)

Pre- or post-doctoral biochemist having experience in immunochemistry or biochemistry of bacteria required for three years for a research project investigating the immune responses to specific components of Streptococci.

Salary according to qualifications and experience, with £502 London Allowance and superannuation.

Apply in writing, with full curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. I.M.2. 2735(A)

CHURCHILL HOSPITAL RESEARCH INSTITUTE
(University of Oxford)

Vacancies exist for two RADIOBIOLOGISTS

in an expanding research group that is examining the biological effects if ionising radiations on a number of normal tissues and organs. These investigations are primarily aimed at improving the treatment of malignant disease by radiotherapy with both conventional photon therapy and fast neutrons. Post suitable for persons with higher degree or equivalent research experience. Responsibilities will depend on the interests and experience of the successful applicants although preference will be given in the case of one vacancy to someone with a qualification in Physics or experience in radiation dosimetry.

Further details can be obtained from Dr J W Hopewell, Churchill Hospital, Research Institute, Headington, Oxford, to whom application should also be sent with the names of two referees by 20th August, 1979. 2670(A)

BRUNEL UNIVERSITY

SCHOOL OF CHEMISTRY

POSTDOCTORAL RESEARCH

CATALYST PREPARATION AND CHARACTERISATION

Applications are invited from suitably qualified candidates for a postdoctoral research appointment on a 2 year SRC-supported programme which will be available from 1 October 1979 or as soon as possible thereafter. The programme, which is supervised by Dr Paul A. Sermon, concerns novel methods of preparing and characterising supported catalysts. A wide variety of techniques is available for catalyst characterisation and testing, including SEM, XPS, XRD and adsorptive and catalytic probes and spectroscopic techniques. Starting salary would be £4,952 per annum but this is under review. Candidates should send a detailed curriculum vitae to Establishment Secretary, Brunel University, Uxbridge, Middx UB8 3PH by 17 August, 1979. 2750(A)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)
Keppel Street, WC1E 7HT

PREVENTIVE TERATOLOGY UNIT

Applications are invited for a

MEDICAL LABORATORY SCIENTIFIC OFFICER IN BIOCHEMICAL TERATOLOGY

to work on congenital malformations associated with environmental agents.

The appointment is for up to 6 months at a salary, depending on age, experience and qualifications, on a scale which rises to £3,930 (under review) + £354 London Weighting.

Applications, stating qualifications and experience and the names of two referees, should be sent to the Secretary (A1) at the School. 2758(A)

Synthetic Organic Chemistry

DELALANDE, an international pharmaceutical group actively involved in research, is expanding the drug discovery programme at its Research Centre and is seeking an additional organic chemist.

Candidates should have a real interest in all aspects of synthetic chemistry and have a PhD with up to one year postdoctoral experience in synthetic organic chemistry.

Knowledge of French is not essential.

The Research Centre is located in the vicinity of Paris.

Applications should be sent to:

Dr M. LANGLOIS
Head, Organic Chemistry
CENTRE DE RECHERCHE DELALANDE
10, rue des Carrières
92500 RUEIL MALMAISON — FRANCE

DELALANDE

W271(A)

HARVARD UNIVERSITY (CDB)

ASSISTANT PROFESSORS OF BIOLOGY

The Cellular and Developmental Biology subdivision of the Department of Biology expects to make one to two appointments at the Assistant Professor level during the next academic year in the fields of Cell Biology and Plant Biology. Applicants should have the PhD; preference will be given to candidates with post-doctoral training, records of outstanding research accomplishment, and teaching experience. Please have three professional persons well acquainted with your work send letters of recommendation directly to the search committee.

Applications should include resumé, copies of most significant publications, and summary of research goals. Send to: Chairman, CDB Search Committee, Department of Biology, Harvard University, 16 Divinity Avenue, Cambridge, Massachusetts 02138.

Women and members of minority groups are specifically encouraged to apply. Harvard University is an Equal Opportunity/Affirmative Action Employer. W270(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PATHOLOGY

RESEARCH ASSISTANT

A Postdoctoral Research Assistant is required immediately to work in the Department of Pathology on a project funded by the Nuffield Foundation, to investigate the pericellular environment of macrophages during connective tissue breakdown.

The work will involve biophysical and biochemical techniques including Ion Specific Micro-electrodes; experience with micro-electrodes and/or cyto-chemistry is desirable. The initial salary will be within the range £4,232 to £5,048 p.a. (Salary scale subject to revision from 1st October, 1979).

For further details, apply to Professor I.A. Silver, Department of Pathology, The Medical School, University Walk, Bristol. BS8 1TD. Completed applications, together with a curriculum vitae and the names of two referees should be lodged by 14th September, 1979. 2783(A)

THE UNIVERSITY OF HULL

UNIT OF GENETICS

GRADUATE RESEARCH ASSISTANT

A Biologist interested in the interactions between animals and plants is required to join a team studying the effects of seed and flower parasites on the reproductive capability of different forms of *Lotus corniculatus* (birdsfoot trefoil). The project is both field and laboratory based and is funded by the SRC. Some experience of electrophoretic techniques and/or of genecology would be advantageous. The appointment is tenable from 1st October 1979 for a period of three years. It may be possible for the successful applicant to register for a higher degree.

Salary will be at the appropriate point on the scale 1B for Research Staff: £3,775 to £5,488.

Further information may be obtained from Professor D A Jones, Unit of Genetics, Department of Plant Biology, Hull, HU6 7RX, to whom applications (two copies) giving details of age, qualifications and experience, together with the names of two referees, should be sent by 27th August, 1979. 2787(A)

HOUGHTON POULTRY RESEARCH STATION

Higher Scientific Officer (Band II)

LIAISON/INFORMATION OFFICER

Applications are invited for the post of Liaison/Information Officer, the duties of which include overall responsibility for a scientific library, liaison with, and an information service for, the poultry industry, veterinary profession, Agricultural Research Council and Ministry, and Press, journals and educational organisations, and the preparation of publications and exhibits.

Applicants should possess a degree, HNC or equivalent in a science subject, with at least 5 years relevant post qualifying experience. Experience in public relations and editorial work would be an advantage. Salary in Higher Scientific Officer grade (£4,727 × 8 to £6,211) salary scale currently under review.

Further particulars from the Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, Cambs PE17 2DA. Closing date for applications Friday, 14th September 1979. 2727(A)

Australian Institute of Marine Science

Senior Research Appointment

The Australian Institute of Marine Science was established as a Statutory Authority of the Commonwealth Government in 1974 and, in 1977, took occupation of a modern and comprehensively equipped laboratory complex at Cape Ferguson, near Townsville, well situated for studies in tropical marine science including phenomena at the land-sea interface, on the complex environment of the Great Barrier Reef and in the adjacent ocean. The ongoing programs of the Institute are augmented by active collaboration and interaction with visiting investigators. Staffing of the Institute is expanding to match developing commitments in comprehensive studies of the marine environment, notably of the tropics. Enquiries are invited from professional researchers interested in a senior appointment in any one of the following fields: Physical Oceanography, Marine Chemistry and Community Ecology. At least one and possibly more are being considered.

Duties: The appointee(s) being sought will be expected to accept a substantial responsibility for guiding and participating in studies aimed at developing a fundamental understanding of the environment of the Great Barrier Reef and its living communities, for encouraging collaborative activity in such studies and, where necessary, to manage contract investigations relevant to assessing responses to real or potential human impact within the region.

Qualifications: The appointee(s) will have received a PhD degree in a relevant field of study, will have had at least 10 years postdoctoral experience and a substantial research reputation. In addition, the appointment will call for experience in and a strong capacity for leadership, the stimulation of scientific interaction and a willingness to accept and execute managerial responsibilities while maintaining a vigorous and effective involvement in research.

Applications should be accompanied by a complete cv, the names of at least 3 but no more than 5 referees and should be forwarded to the address given below no later than August 31, 1979.

The Secretary, Australian Institute of Marine Science, P.M.B. No. 3, Townsville M.S.O. 4810, Queensland, Australia. 2759(A)

UNIVERSITY OF MANCHESTER
DEPARTMENT OF PATHOLOGY
A RESEARCH ASSISTANT

is required to participate in a study of ageing in the human placenta. The work will consist mainly of Electron microscopy. Initial salary £3,775 p.a. Applications to Professor H. Fox, Department of Pathology, Stopford Building, Oxford Road, Manchester M13 9PT. 2740(A)

To place your advertisement in these pages Phone: 01-831-6901

ANALYTICAL CHEMIST FOR NFT NURSERY IN SUSSEX

Nutrient Film Technology Ltd is a new and expanding company engaged in both primary production and associated research and development programmes connected with the nutrient-film technique. We require an analytical chemist to operate an atomic absorption spectrophotometer, a visible spectrophotometer and a specific ion meter, as an aid to developing programmes for commercial crop production in the UK and overseas.

This is an excellent opportunity for a young and enthusiastic person to become involved in an exciting new venture.

Apply to: Dr. A. J. Cooper, Managing Director, Nutrient Film Technology Ltd, Hook Lane, Aldingbourne, Chichester, W. Sussex, PO20 6TE. 2760(A)

UNIVERSITY OF SINGAPORE
PROFESSORSHIP IN ZOOLOGY

Applications are invited for the post of Professor in the Department of Zoology. Applicants should possess outstanding academic qualifications, have considerable University teaching and research experience, supported by authoritative publications. The successful candidate will be expected to provide leadership to the teaching and research programmes of the department. The major areas of research are ecology (with an emphasis on aquatic aspects) and comparative physiology, but developing lines of research include taxonomy, biometrics and genetics. Gross monthly emoluments range from S$4044/- to S$6236/-, the initial amount depending on the candidate's qualifications and experience. In addition, the University pays a 13th month annual allowance of one month's salary in December of each year.

Leave, medical and provident fund benefits are available. The University at present contributes to the staff member's provident fund at the rate of 16½% of his monthly salary. Subsidised housing will also be provided at current rentals ranging from S$100/- to S$350/- p.m.

Candidates should write to: *The Registrar, University of Singapore, Kent Ridge, Singapore 0511,* giving curriculum vitae (bio-data), with full personal particulars and also the names and addresses of three referees. W274(A)

ROTHAMSTED EXPERIMENTAL STATION
Harpenden, Herts AL5 2JQ

ENTOMOLOGIST

required to work on the overwintering mortality and migratory behaviour of aphids infesting potato crops in spring. Three-year post funded by the Potato Marketing Board.

Qualifications: 1st or 2(1) hons. degree in Zoology, Applied Entomology or Agricultural Zoology.

Appointment in the grade of Scientific Officer £3,289 to £5,085 (£3,591 to £5,486 from 1.1.80). Starting salary according to qualifications and experience. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees and quoting Ref. 403 by 9th August, 1979. Further details on request. 2793(A)

UNIVERSITY OF MANCHESTER

RESEARCH ASSOCIATE IN MEDICAL BIOCHEMISTRY

Applications invited from post-doctoral candidates for this post (available for three years) to work on "The Synthesis and Secretion of Elastin". Some experience in the field of nucleic acid isolation, protein synthesis or connective tissue biochemistry would be an advantage.

Starting salary in the range £4,333 to £4,910 p.a.

Applications with full curriculum vitae and the names of two referees should be sent as soon as possible to: Dr M.E. Grant, Department of Medical Biochemistry, University of Manchester, Medical School, Manchester M13 9PT. 2771(A)

THE UNIVERSITY OF HULL
DEPARTMENT OF BIOCHEMISTRY
RESEARCH TECHNICIAN
Grade 3

is required for an established post for varied and interesting work in the Departmental Chemostat and Fermenter Suite. Minimum qualifications: ONC in Sciences (or equivalent) plus 3-4 years background experience in Biochemistry. Additional experience in Microbiology would be advantageous. Salary on the scale £2,931 to £3,336 per annum.

Applications giving details of age, qualifications, experience and the names of two referees should reach the Technical Staff Officer, University of Hull, HU6 7RX by Friday, 17 August 1979 quoting Ref. No. TBCH/4. 2786(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF GENETICS

Applications are invited from graduates in a suitable discipline for the post of

RESEARCH ASSISTANT

to work with Dr P. Strike on error-prone DNA repair processes enhanced by bacterial plasmids. The project, which is supported by the S.R.C., if financed for a period of three years from 1st October, 1979, and will involve both conventional genetic techniques and *in vitro* DNA manipulation. Initial salary will be £3,689 p.a. The possibility exists for a suitable candidate to register for the degree of PhD.

Applications, together with the names of three referees, should be received as soon as possible, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/717/N 2745(A)

UNIVERSITY OF BRISTOL
SCHOOL OF CHEMISTRY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistant to join a group investigating the metabolism of gibberellins in higher plants. Some experience in the synthesis of isotopically-labelled compounds would be advantageous.

The appointment, funded by the SRC, is for a maximum of two years. Salary in the range £4,232 to £4,776 p.a. (scale subject to revision from 1st October, 1979).

Applications, enclosing a curriculum vitae and the names of two referees should be sent to Professor J. MacMillan by 31st August, 1979. 2650(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BIOCHEMISTRY
TECHNICIAN GRADE 5 (ELECTRON MICROSCOPY)

For Electron Microscope unit to carry out work in association with several research groups. Applicants should posses HNC or equivalent as minimum qualification and graduates would be welcome. Candidates should possess experience in Electron Microscopy.

Salary within a range of £3,474 to £4,056 p.a.

Application forms available from The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/723/N 2746(A)

FLOUR MILLING AND BAKING RESEARCH ASSOCIATION

MICROBIOLOGIST

The Flour Milling and Baking Research Association carries out a wide range of research and service work for the Milling and Baking Industries and holds a number of research contracts from the Ministry of Agriculture, Fisheries and Food. The laboratories are situated in an attractive semi-rural area on the edge of the Chilterns with ready access to London.

A GRADUATE MICROBIOLOGIST

is required to work on applied research topics and on microbiological problems of the milling and baking industries. Candidates should have experience of food microbiology and preferably have spent some time in the food industry. Preferred age, under 30; salary on the Scientific Officer (£3,194 to £4,767) or Higher Scientific Officer (£4,530 to £5,903) scales, entry position depending on experience.

Applications, including the names of two referees, should be sent to Professor Brian Spencer, Flour Milling and Baking Research Association, Chorleywood, Rickmansworth, Herts. WD3 5SH, from whom further details of the work of the Research Association may be obtained. 2732(A)

QUEEN ELIZABETH COLLEGE, KENSINGTON (Universiy of London)

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Quadrupole double resonance

Applications are invited for a post-doctoral research post, tenable for two years, in double resonance spectroscopy with particular reference to the detection of ^{17}O and ^{33}S quadrupole resonance in natural abundance in solids. Candidates should be graduates in Chemistry, Physics, or Chemical Physics and should have recently obtained, or expect shortly to obtain, a PhD degree. An interest in instrumentation and/or computing would be an additional qualification.

This post is funded by S.R.C. and has a salary (under review) in range £4,763 to £5,307 (including London allowance). Applications with a curiculum vitae and the names of two referees should be sent to: Professor J.A.S. Smith, Department of Chemistry, Queen Elizabeth College, Campden Hill Road, London, W8 7AH. 2723(A)

MLSO/

DEPARTMENT OF MEDICINE

Applications are invited for a research technician to assist in initiating a programme studying protein metabolism and in lung disease. Applicants should hold relevant HNC or equivalent and must be experienced in biochemical techniques with experience in chromatography and surgical techniques an advantage.

Applications in writing, stating date of birth, qualifications, career details and the names of two refeerees should be sent to The Secretary, Cardiothoracic Institute, Fulham Road, London, SW3 6HP. Quote Ref BC-1-79. 2731(A)

LONDON UNIVERSITY

CARDIOTHORACIC INSTITUTE, DEPARTMENT OF MEDICINE.

JUNIOR or MEDICAL LABORATORY SCIENTIFIC OFFICER

equired. Experience in immunology lesirable. Work will mainly involve the aboratory investigations of mmunological responses in patients with ung cancer.

Further information and applications, iving details of age and experience to: Mr. R.A. Perkins, Secretary, Cardiothoracic Institute, Fulham Road, London, SW3 6HP, quoting Ref 01/79. 2780(A)

HERIOT-WATT UNIVERSITY

MARINE TECHNOLOGY CENTRE

RESEARCH ASSOCIATES

Applications are invited for Research Associates in the SRC supported Heriot-Watt Marine Technology Centre.

The Centre is seeking to recruit graduates for work in Marine Technology and related fields; subjects include marine instrumentation, underwater plasma operations, aquaculture engineering, physical modelling of single-point moorings, offshore supply vessels, theoretical modelling of residual currents, dynamics of offshore cranes, concrete coating pipelines.

Applicants should have an Engineering or Science based degree. These posts offer an excellent opportunity for both new graduates and those already experienced in Marine Technology to develop specialised expertise in areas related to the offshore industry.

The work content involves theoretical studies, experimental work and also offshore trials.

Salaries: £3,689 to £6,108 (expected to be £3,775 to £6,355 p.a. with effect from 1 October 1979) depending on qualifications and experience.

Application forms from the Staff Office, Chambers Street, Edinburgh EH1 1AX. Ref. No. 107/79. 2733(A)

AGRICULTURAL RESEARCH COUNCIL

INSTITUTE OF PHYSIOLOGY

Babraham, Cambridge, CB2 4AT.

SCIENTIFIC OFFICER

required to assist with research in neurochemistry. H.N.C., pass degree in appropriate subject, or equivalent. Chemical knowledge essential. The position is financed by the Medical Research Council, at present until the 30th September 1980.

Salary in scale £3,289 to £5,085 p.a. according to qualifications and experience. Non-contributory superannuation scheme. 4 weeks paid annual holiday.

Applications with full details should be sent to the Secretary of the Institute quoting Ref. M.R.C.6. by the 13th August 1979. 2794(A)

Public Health Laboratory Service

Centre for Applied Microbiology & Research. Porton Down

Immunologist or Biochemist

The Vaccine Research & Production Laboratory has a vacancy for an **Immunologist or Biochemist** with immunological experience to take a leading role in developing a programme concerned with methods for the assessment of potency and safety of vaccines. Preference will be given to candidates with an interest in developing animal model systems.

Appointment may be at either Senior Grade (£5,451 to £6,837) or Basic Grade Microbiologist (£2,991 to £4,899) depending upon qualifications and experience. A good honours degree or equivalent is essential and for a Senior Grade position a record proven research ability. Salaries are under review.

Further details of the posts can be obtained from Dr J. Melling, Director, Vaccine Research & Production. Tel 0980-610391.

Applications stating date of birth, qualifications, experience and publications and naming three referees should be sent to Mrs M.Bushby, CAMR, Porton Down, Salisbury, Wilts SP4 0JG by 1 September 1979. 2799(A)

PHLS

UNIVERSITY OF GLASGOW

DEPARTMENT OF VETERINARY PHARMACOLOGY

RESEARCH ASSISTANT

Applications are invited for appointment as a Research Assistant in the Department of Veterinary Pharmacology.

The project is to study adrenergic mechanisms in the horse, using both *in vivo* and *in vitro* techniques. Experience in radiological methods and catecholamine assays would be helpful.

This project is funded by the Horserace Betting Levy Board and the position is available in the first instance for two years.

Applications can be made to Dr D Snow, Department of Veterinary Pharmacology, Veterinary School, Bearsden Road, Bearsden, Glasgow G61 1QH. 2761(A)

UNIVERSITY OF BRISTOL

School of Chemistry

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant to continue studies on the identification of reaction products from the ozonisation of organic compounds in potable waters. Instrumentation includes HPLC, capillary GLC and computerised GC-MS. Technical assistance is available. The project is financed by the Water Research Centre and relates to the purification of drinking water by ozone.

The appointment is for one year, with the possibility of renewal for a second year. Starting salary within the range £4,232 to £5,048 per annum. (Scale subject to revision with effect from 1st October, 1979).

Please send applications, by 20th August, with details and the names and addresses of two referees, to Dr J R Maxwell, Organic Geochemistry Unit, School of Chemistry, University of Bristol, Bristol BS8 1TS. 2749(A)

GUY'S HOSPITAL

DEPARTMENT OF HAEMATOLOGY

QUALIFIED LABORATORY SCIENTIFIC OFFICER

(H.N.C. or equivalent) required until 31st March 1981 for M.R.C. research project to study nutritional and biochemical aspects of vitamin K in the human. Previous experience in analytical techniques used in lipid biochemistry desirable but not essential.

Salary for candidate qualified as above not less than £3,261 (under review) plus £354 London Weighting.

Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. H.M.1. 2736(A)

NUFFIELD INSTITUTE FOR MEDICAL RESEARCH

University of Oxford (on John Radcliffe Hospital site)

MEDICAL LABORATORY SCIENTIFIC OFFICER (WHITLEY COUNCIL)

The post involves assisting with research related to fetal development and its regulation. Experience in radio-chemical techniques is desirable.

Applicants should be state registered MLSO or possess an appropriate science degree or equivalent qualification together with at least one year's relevant laboratory experience. The post is available immediately. Salary scale £3,261 to £4,680 pa (as at 1 April 1978).

Applications (please quote ref MRC/R) with curriculum vitae and citing the names and addresses of two referees should be sent to The Administrator, Nuffield Institute for Medical Research, Headley Way, Headington, Oxford, OX3 9DS, by 15 August 1979. 2767(A)

COLAISTE NA HOLLSCOILE CORCAIGH
UNIVERSITY COLLEGE CORK
RESEARCH FELLOWSHIP

BIOCHEMICAL GENETIC/BACTERIAL PHYSIOLOGIST

required to work on regulatory aspects of nitrogen fixation in Rhizobium.

Minimum qualifications: First or upper second class honours degree in appropriate subject and at least two years relevant post-qualifying experience. Preference will be given to applicants with a PhD, degree. This post, funded by the National Board for Science and Technology, is tenable for up to 3 years and available from 1 October 1979. The salary range is £3,365 to £4,476 (post-doctoral £3,837 to £4,476) and starting salary will depend on experience (salary under review).

Applications, giving full particulars of qualifications and experience and names of two referees should be sent to:
Dr F. O'Gara, Department of Microbiology, University College, Cork, (Ireland).
2801(A)

COLAISTE NA HOLLSCOILE CORCAIGH
UNIVERSITY COLLEGE CORK
RESEARCH ASSISTANT

A Research Assistant is required for 1 October 1979 with postgraduate experience in enzyme purification and characterisation to work on oxygen and hydrogen peroxide metabolism in latic acid bacteria.

Candidates should preferably have a PhD in microbiology/biochemistry. The appointment is funded by the National Board for Science and Technology of Ireland. Starting salary is £3,837 for a post-doctoral worker (salary under review). The post is renewable for a second year.

Curriculum vitae with names of two referees should be sent to:
Dr S. Condon, Department of Microbiology, University College, Cork, (Ireland).
Closing date for receipt of applications: Friday, 31st August 1979. 2082(A)

UNIVERSITY OF WARWICK

POSTGRADUATE RESEARCH ASSOCIATE

in the

DEPARTMENT OF CHEMISTRY AND MOLECULAR SCIENCES

Applications are invited to the SRC funded post of Postgraduate Research Associate to work with Dr O.W. Howarth on a ^{13}C nuclear magnetic resonance study of the physical dynamics of biomolecules and macromolecules. Candidates should hold a good honours degree in chemistry or biochemistry.

A suitably qualified candidate will be permitted to register for a higher degree on appointment. The post is tenable for three years with a starting salary up to £4,333 p.a. on the Research Range 1B scale £3,775 to £5,488 p.a. depending on age and experience.

Applications, together with the names of two referees, should be sent as soon as possible to the Academic Registrar, University of Warwick, Coventry, CV4 7AL. Please quote Ref.No: 52/2A/79.
2785(A)

CENTRAL PUBLIC HEALTH LABORATORY

DIVISION OF ENTERIC PATHOGENS

MEDICAL LABORATORY SCIENTIFIC OFFICER

Suitable qualifications would be A.I.M.L.S., a relevant science degree or H.N.C. with experience in Microbiology.

The post is in the phage-typing and drug resistance unit. The successful applicant is to assist in the routine work of the unit but will be expected to participate in the research program. The officer would be encouraged to work for higher qualifications such as F.I.M.L.S. by thesis or higher degrees.

The Division of the National Reference Centre for Salmonella, Shigella and Escherichia coli. The World Health Organisation Collaborative Centre for Phage-typing and Drug Resistance of Enterobacteria is located in the Division.

Applications with full details of age, experience and qualifications to the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London N.W.9. 5 H.T. Telephone 01 205 7041.
2737(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL
(University of London)
Denmark Hill,
London SE5 8RX

DEPARTMENT OF OBSTETRICS & GYNAECOLOGY

Applications are invited from graduates or suitably qualified people for the post of

RESEARCH TECHNICIAN

on a project involving tissue culture and cytogenetics and some histological and histochemi techniques in the area of pre-natal diagnosis of inherited diseases. Starting salary £3,669 inclusive (under review).

For informal enquiries please contact Dr J Singer on 01 274 6222 extension 2349. Applications in writing giving full details of qualifications and experience should be sent to the Secretary of the Medical School at the above address by 19th August, 1979. (Previous applicants need not re-apply.)
2770(A)

UNIVERSITY OF BRISTOL

LECTURER IN MEDICAL MICROBIOLOGY (VIROLOGY)

Applications are invited from honours science graduates, with experience of microbiology, for the post of Lecturer in Medical Microbiology (Virology). Salary scale £4,232 to £8,452 per annum, (under review), together with superannuation.

The lecturer will work mainly in the laboratories of Bristol Royal Infirmary, and responsibilities will include clinical laboratory work, teaching of medical students and research. Training will be provided in clinical virology, and in other aspects of medical microbiology. Applications, giving full details of age and experience, together with the names and addresses of three referees, should be sent by 25th August, 1979, to the Registrar and Secretary, University of Bristol, Senate House, Bristol, BS8 1TH, from whom further particulars may be obtained. Please quote reference TLJ. 2765(A)

UNIVERSITY OF DUNDEE

DEPARTMENT OF CHEMISTRY

There is a vacancy for a

POSTDOCTORAL RESEARCH ASSISTANT

to work with Dr J.A. Miller in the above Department on the synthesis of organic molecules designed to interact favourably with DNA.

The appointment will be available for one year from 1 October 1979 (or same later date agreed). Salary within the range £4,333 to £4,910. Superannuation under USS.

Applications containing details of age, qualifications and research experience and the names of two referees should be sent by 20 August 1979 to The Secretary, The University, Dundee, DD1 4HN. Please quote Ref: EST/76/79 J 2743(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF ZOOLOGY

POST-DOCTORAL RESEARCH ASSISTANT

required from 1st October 1979, for a three-year project on control of lipogenesis and membrane biogenesis during hormone-induced cell differentiation in avian liver. Research experience in biochemistry or a related field is essential and experience of cell culture/immunochemistry would be an advantage.

Initial salary in the range £4,333 to £4,910 per annum within range 1A, plus superannuation.

Applications (3 copies) including curriculum vitae and naming three referees should be sent by 10 August 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham, DH1 3LE, from whom further particulars may be obtained. 2655(A)

RESEARCH ASSISTANT required for three years to work on a CRC financed project on the invasiveness of malignant cells in culture. Applicants should have a good degree in the Biological Sciences with some training in Cell/Developmental Biology or related subjects and post-graduate experience in one or more of the following fields will be an advantage: Tissue culture techniques and light microscopy of cultures. Quantitative analysis of motile behaviour in cells. Tumour cell biology. Biochemistry/biophysics of contractile systems. The successful applicant will be expected to show some resourcefulness in the design and interpretation of experiments. Starting date October 1979, starting salary up to £4,300 pa (depending on age and qualifications). Please apply in writing, enclosing a full curriculum vitae and the names of two referees to: Dr G A Dunn, Strangeways Research Laboratory, Wort's Causeway, Cambridge, CB1 4RN.
2729(A)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

TECHNICIAN 5

(IMMUNOLOGY)

required to assist in a project unde Dr B. Anderton involving the isolation o brain proteins and the production o monoclonal antibodies to those proteins HNC/degree and experience in protei chemistry, or immunochemistry or tissu culture essential.

The appointment is for 3 years and i sponsored by the Wellcome Trust Emoluments £3,474 to £3,699 (unde review) plus £275 p.a. London allowance Application forms and further particular from the Sector Administrator, Sector 2 St. George's Hospital Medical School Cranmer Terrace, Tooting, SW17 0RE Closing date 3rd September 1979.

THE ROYAL SOCIETY

ROYAL SOCIETY METEOROLOGICAL OFFICE RESEARCH FELLOWSHIP IN DYNAMICAL METEOROLOGY

Applications are invited by the Council of the Royal Society for a

ROYAL SOCIETY METEOROLOGICAL OFFICE RESEARCH FELLOWSHIP IN DYNAMICAL METEOROLOGY

tenable in the department of atmospheric physics, University of Oxford. Candidates should supply the usual personal details and the names of two referees, together with a full description of the research proposed.

The appointment, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from a date to be mutually agreed in the academic year starting on 1 October 1979. The commencing salary which will depend on age and experience, will be within the scale £4,863 to £8,019 per annum, with appropriate superannuation benefits.

Applications should be made on forms to be obtained from The Executive Secretary, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG, and should be received not later than 30 September 1979. 2772(E)

THE QUEEN'S UNIVERSITY OF BELFAST

RESEARCH FELLOWSHIP

DEPARTMENT OF MICROBIOLOGY & IMMUNOBIOLOGY

This post involves work on macromolecular aspects of neurological disease. Preference will be given to applicants with experience in virology, immunology, particularly in immunassay methods and/or mucleic acid hybridization techniques. The fellowship is tenable for two years but may be renewable for a third year. Salary in the range of £6,000 to £7,000.

Application forms may be obtained from the Personnel Officer, the Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date 14th September, 1979. 2752(E)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF GEOLOGICAL SCIENCES

STUDENTSHIP IN URANIUM-THORIUM HYDROCHEMISTRY

Applications are invited for the above studentship. The study will include the measurement of uranium and thorium isotope concentrations in groundwater and the interpretation of their hydrogeological significance and the studentship holder will be permitted to work for the degree of PhD. The work is supported by a research grant from the Harwell Research Establishment. Applicants should have a good honours degree or an MSc in Chemistry or Geology or Physics. The Studentship is tenable for three years.

Applications should be sent as soon as possible to the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT. 2781(F)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for an

SRC POST DOCTORAL FELLOWSHIP

available for suitably qualified candidates to work with Dr J W T Wimpenny in the

DEPARTMENT OF MICROBIOLOGY

on quantitative aspects of the growth of micro-organisms in solute gradients. The successful applicant will join a group investigating the biology of three different diffusion systems, and will be responsible for generating mathematical models capable of defining and predicting the growth and interactions of organisms in solute gradients. Applicants are sought from relevant subjects disciplines including for example chemical or biochemical engineering, physical chemistry, operational research, computing science, and pure or allied mathematics.

The appointment is for 2 years from October 1st, 1979 at a starting salary of £4,333 (under review).

Applications (2 copies) including curriculum vitae and the names and addresses of two referees should be forwarded to the Vice-Principal (Administration) and Registrar, University College, PO Box 78, Cardiff CF1 1XL, as soon as possible. Reference 1870. 2748(E)

POST DOCTORAL FELLOWSHIP available for work on the causation of lung cancer by environmental and industrial metal particulates and the possible interaction of these with systemic agents. The project is based in Cambridge and involves collaboration with the Industrial Toxicology Unit of the Dept of Safety and Hygiene, University of Aston. Funding is provided by a 3 year grant from the Health and Safety Executive starting 1st October 1979. MRC conditions of service, starting salary in the range £5,048 to £5,850 depending on age and qualifications. Applications (2 copies) from persons with good previous experience of the techniques of experimental pathology should be forwarded to Administrative Secretary, Strangeways Research Laboratory, Worts Causeway, Cambridge CB1 4RN, together with full c.v. and the names of two referees. 2728(E)

UNIVERSITY OF LONDON KING'S COLLEGE

DEPARTMENT OF PHYSIOLOGY

Applications are invited for a three year MRC-financed

POST-DOCTORAL FELLOWSHIP,

initial salary on scale 1A, £4,333 p.a. plus London Allowance £502 p.a. effective from 1st October 1979.

The project involves electron-probe, physiological and electron microscopical studies of solute and water transport in rabbit ileum. The work will be at two centres, the physiological part at King's College London under Dr R.J. Naftalin and the electron microprobe and electron microscopy in the Zoology department, Cambridge, under Dr B. Gupta. Provision for travel and short stay expenses in Cambridge. Applications and names of two referees to Dr R.J. Naftalin, Department of Physiology, King's College, Strand, London WC2, telephone 01-836 5454. 2796(E)

SENIOR RESEARCH FELLOW IN ATOMIC/ MOLECULAR PHYSICS

The University of Maryland and the National Bureau of Standards in Washington, D.C. are announcing a one year fellowship for a senior research scientist to pursue research at the NBS Synchrotron Ultraviolet Research Facility (SURF). The SURF fellow will hold an appointment in the Institute of Physical Science and Technology at the College Park Campus of the University of Maryland. In addition to his research activities at SURF, the appointee will interact with the faculty and students at the University, principally through lectures and seminars.

Applications are now being accepted for the academic year 80-81, with detailed schedule to be negotiated. Salary and faculty rank will be commensurate with current position. We are initially seeking an individual interested in pursuing atomic/ molecular physics at SURF. Experience in the use of synchrotron radiation and/or photoelectron spectroscopy of gases will be considered particularly valuable for the appointment.

Send resume, desired starting date, and research plans to:
Prof. Joseph Silverman, Institute for Physical Science and Technology, University of Maryland, College Park, Maryland 20742. W267(E)

UNIVERSITY OF NOTTINGHAM

SRC. RESEARCH FELLOWSHIP IN PHARMACEUTICAL CHEMISTRY

Applications are invited for this post which is tenable for two years. This is a joint project between Professor B.W. Bycroft (Pharmacy) and Dr M.A.F. Dove (Chemistry) and concerns the application of fluorinated amino acids as reporter groups for the study of peptide antibiotic and protease inhibitors.

Salary in the range £4,333 to £4,910 per annum depending on age and qualifications. Applications in writing including full curriculum vitae and the names of two referees to the Staff Appointments Officer, University of Nottingham, Nottingham, NG7 2RD. 2773(E)

UNIVERSITY OF KENT AT CANTERBURY

RESEARCH FELLOWSHIPS IN CHEMISTRY

Applications are invited for three Post-Doctoral Research Fellowships in connection with the following research projects:

(i) Kinetics of fast reactions in solution by laser flash and temperature-jump apparatus and high-pressure cell (with Professor E.F. Caldin and Dr B.H. Robinson).

(ii) Tunnelling in proton-transfer and hydrogen-atom-transfer reactions in solution (with Professor E.F. Caldin).

(iii) Kinetics of very fast reactions in solution by microwave temperture-jump method (with Professor E.F. Caldin).

The projects are supported by the Science Research Council and the appointments will be for a minimum period of two years. Salary range — £4,232 to £5,321 (under review). Application forms and particulars may be obtained from the Senior Assistant Registrar, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH to whom applications should be returned by 31 August 1979. Please quote ref: A42/79. 2800(E)

FELLOWSHIPS

UNIVERSITY OF NOTTINGHAM

POST-DOCTORAL RESEARCH IN ENVIRONMENTAL SCIENCES

Fog interception by vegetation — a pathway for pollutant deposition

A post-doctoral research fellowship is available for study of the quantity and quality of fog water captured by shrubs, trees and extensive forests exposed to wind-blown fog and low cloud. In areas where fogs contain dissolved air pollutants it is believed that fog capture may be an important and previously unmeasured pathway for pollutant deposition. The project is in collaboration with the Institute of Terrestrial Ecology, Penicuik, Edinburgh, where some of the field studies will be made.

Applicants with backgrounds in environmental sciences, or in physical, chemical or biological science will be considered. The post is funded by the Natural Environment Research Council for three years, starting as soon as possible. Salary in the range £4,333 to £4,910 p.a.

Applications, including curriculum vitae and names of two referees should be sent to Dr M.H. Unsworth, Department of physiology and Environmental Studies, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough, Leics. U.K., from whom further details are available. 2742(E)

PRESTON POLYTECHNIC

SRC POSTGRADUATE RESEARCH STUDENTSHIP

Applications are invited for an SRC Postgraduate Studentship on one of the following topics: 1) Climatic and biotic factors governing the colonisation of timber joinery by micro-fungi; 2) Photo-synthesis in algae and bacteria; 3)Energy metabolism: effects of diet and exercise.

For further information, interested persons should telephone The School Clerk (Chemistry and Biology), on Preston 51831 ext. 250. 2789(F)

UNIVERSITY OF WARWICK

RESEARCH FELLOWSHIP IN VIROLOGY

Applications are invited for a Postdoctoral Fellowship in the Tumour Virus Research Group in the Department of Biological Sciences. The successful applicant will work in a small group using molecular biology (including recombinant DNA) techniques to study mouse RNA tumour viruses, with particular reference to their ability to transform cells.

Starting salary will be between points 1 and 6 on the Research 1A scale: £4,333 (£5,777) £7,145 p.a. The Fellowship (funded by the Medical Research Council) is available from 1st October, 1979 and is renewable on an annual basis until September 1981.

Further details can be obtained from Dr R.J. Avery in the Department of Biological Sciences. Application forms from the Academic Registrar, University of Warwick, Coventry, CV4 7AL quoting Ref.No. 52/A/79. Closing date for receipt of applications is 24th August 1979. 2784(E)

FELLOWSHIPS continued

UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

Biochemistry Laboratory

RESEARCH FELLOWSHIP IN CELL BIOLOGY

A postdoctoral fellowship is available for the study of the involvement of cyclic nucleotides in the regulation of the differentation of muscle. The project, which is financed by the MRC, is specifically concerned with the mechanism of action of cyclic AMP and will involve an examination of protein kinase activities and protein phosphorylation in chick myoblasts as they prepare to differentiate *in vitro*. Experience with tissue culture techniques and two dimensional gel electrophoresis, would be an advantage. Available from 1 September 1979 for two years in the first instant. Initial salary will be in the range £4,232 to £4,776 per annum (scale under review from 1st October 1979).

Applicants should send curriculum vitae and names of two referees to Dr Rosalind Zalin, School of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG, Sussex. 2751(E)

FELLOWSHIP AT THE FRIEDRICH MIESCHER-INSTITUT, Basel, Switzerland

In the Friedrich Miescher-Institut, a fellowship (2-3 years) is available for a PhD or MD in a research group examining the role of endogenous C-type viruses in leukemogenesis and lymphocyte function. Salary in accordance with the Swiss National Foundation. Travel costs will be covered.

Candidates, preferably with experience in immunology, virology or nucleic acid chemistry, please write to:
Dr Christoph Moroni, Friedrich Miescher-Institut, P.O. Box 273, CH-4002 Basel, Switzerland. W253(E)

QUEEN MARY COLLEGE
University of London

CHEMISTRY DEPARTMENT

Applications are invited for a Postdoctoral

RESEARCH FELLOWSHIP

funded by Hoffmann-La Roche to investigate with Dr G P Moss the structure of caroteno-proteins by the synthesis and recombination of modified carotenoids and a study of the physical properties of the products. Initial salary in range (under review) £4,835 to £5,412 pa (including London Allowance).

Applications, with curriculum vitae and the names and addresses of two referees, should be sent to The Registrar, (N) Queen Mary College, Mile End Road, London E1 4NS. 2776(E)

COURSES

COMBUSTION FUNDAMENTALS

A one week course of post experience lectures will be held at Imperial College from 22 to 26 October 1979. Details from Professor F.J. Weinberg, Department of Chemical Engineering and Chemical Technology, Imperial College, London SW7 2BY. 2722(D)

STUDENTSHIPS

THE ROWETT RESEARCH INSTITUTE

Greenburn Road, Bucksburn, Aberdeen, AB2 9SB

A.R.C. RESEARCH STUDENTSHIP

Applications are invited for the award of a Post-graduate Research Studentship of the Agricultural Research Council tenable for three years, from October 1979, in the Lipid Biochemistry Department for work on metabolic inter-relationships between lipid and protein metabolism.

Candidates should have a first or upper second class Honours degree (preferably in biochemistry) and will be expected to register for a higher degree. The Studentship comprises a tax-free maintenace allowance of £1,820 p.a., plus compulsory fees and travelling expenses.

Further particulars may be obtained from the Secretary, Rowett Research Institute, Bucksburn, Aberdeen, AB2 9SB, to whom applications (giving details of career to date) should be sent. 2792(F)

FOR SALE and WANTED

ALMOST ANY SCIENTIFIC and learned periodicals, proceedings, transactions etc. wanted in long and complete runs/sets. H. Pordes Ltd., 529B Finchley Road, NW3 7BH. Tel: 01-435 9878 after 2 p.m. 2673(L)

AWARDS

ASSISTANTSHIPS

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF CHEMISTRY AND DEPARTMENT OF MATERIALS SCIENCE

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANTSHIP

tenable from October 1st 1979 for 3 years to work with Professor W.J. Albery and Dr B.C.H. Steele on the development on novel oxide electrodes for fuel cells and solid state oxygen sensors. The research assistant will be responsible for applying advanced electrochemical techniques to the elucidation of the kinetics and mechanism of the oxygen reaction and for the design and development of new materials for these electrodes. The project is part of the Oxford Imperial Energy Group.

Initial salary of up to £4,776 plus £29 supplement plus £502 London allowance (under review from1-10-79).

Applications with curriculum vitae should be sent to Professor J. Albery, Department of Chemistry, Imperial College, London SW7 2AY. 2797(P)

UNIVERSITY OF OXFORD

DYSON PERRINS (ORGANIC CHEMISTRY) LABORATORY

POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a postdoctoral Research Assistantship supported by the S.R.C. to investigate the mechanism of action of enzyme catalysed phosphoryl and nucleotidyl transfer reactions. Experience in phosphate chemistry and enzymology is desirable.

The appointment is for one year from 1st October or as soon as possible thereafter. The salary will be on the Research Support Grade Scale 1A, initially not higher than £4,776 per annum plus U.S.S. benefits.

Applications, with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr G. Lowe, Dyson Perrins Laboratory, South Parks Road, Oxford. OX1 3QY. 2768(P)

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

Applications are invited for an SRC funded

POSTDOCTORAL SENIOR RESEARCH ASSISTANTSHIP

tenable for 2 years from 1st October, 1979 to work in the field of Gamma Ray Astronomy with Professor A W Wolfendale FRS, and Dr A W Strong.

The work involves analysis of gamma ray data accumulated by satellite borne detectors and has as a major objective a study of the distribution of cosmic ray particles in the Galaxy (and beyond) whose interactions with the interstellar gas generate some of the quanta. Preference will be given to applicants with Research experience in Galactic structure, the interstellar medium or related fields. Computer experience would also be an advantage.

Initial salary in the range £4,333 to £4,910 on Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by 31st August 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE from whom further particulars may be obtained.

Further particulars: Applications are invited for a Science Research Council supported Postdoctoral Senior Research Assistantship to work in the field of Gamma Ray Astronomy with Professor A W Wolfendale FRS, and Dr A W Strong.

The work is part of a programme relating to elucidating the origin of cosmic rays and the way in which they are propagated through the Galaxy and through space in general. Some of the gamma rays originate in interactions with gas in the ISM and a detailed analysis of gamma ray arrival directions coupled with a knowledge of the distribution of gas in the Galaxy and beyond allows cosmic ray intensity distributions to be examined.

Data from satellite-borne detectors (principally COS-B) are the main source of gamma ray information and this is analysed along with a variety of radio data on the distribution of H, CO.. in space.

The Research Assistant will work primarily in Durham (where good computing facilities exist) but opportunities exist for visits to other laboratories, largely in Europe.

The appointment will be for 2 years from 1st October, 1979, or as soon as possible thereafter. 2754(P)

AWARDS

UNIVERSITY OF GLASGOW

SRC CASE AWARDS

Applications are invited for two CASE awards in the Department of Chemistry for work on the following projects:

1. "A molecular interpretation of transport properties of dense fluids and fluid mixtures."
2. "Thermal conductivities of dense fluid mixtures."

Each project involves some experimental work at elevated pressures which will be carried out at the National Engineering Laboratory, East Kilbride.

The co-operating body will supplement the SRC Studentship rate by £500 p.a.

Applicants should possess a good honours degree. Further details may be obtained from Dr. J. H. Dymond, Department of Chemistry, University of Glasgow, Glasgow, G12 8QQ. In reply please quote Ref. No. 4491M. 2788(N)

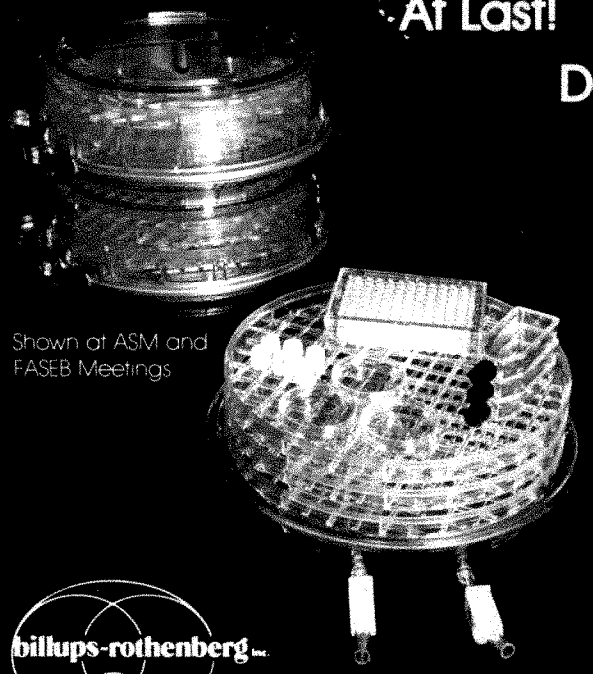
BACK PAIN ASSOCIATION

offers a Medal and honorarium of £200 for outstanding new work in the field of back pain. To qualify, the work must have been presented to a scientific meeting or published in a scientific journal in the English language during the year ending 30th September 1979.

In the event of two candidates being adjudged winners, the honorarium will be divided equally and each candidate will receive a medal.

There are no restrictions as to nationality or academic qualifications but particular consideration will be given to the work of young researchers.

The Association shall have the right to publish a synopsis of the work or to reprint the complete paper providing that, if it has already been published elsewhere, copyright permission shall have been obtained.



The Awards Committee reserve the right to withhold the award.

All submissions, which should be fully documented, will be considered by the Awards Committee and must reach The Back Pain Association, Grundy House, Somerset Road, Teddington, TW11 7TD not later than 30th September 1979. 2769(N)

At Last! A Reliable Incubator Under $100

Designed for Aerobic or Anaerobic Tissue Culture Experiments

Shown at ASM and FASEB Meetings

With this Modular Incubator Chamber you no longer have to worry about the inherent variability (due to CO_2, temperature and humidity fluctuations) of present day continuous flow and anaerobic incubators

Simply place your experiment into the sealed chamber, purge the system with the required gas mixture and set in a controlled temperature environment

Because each chamber is an isolated system you now have the flexibility to design experiments you previously thought were impractical or too expensive

Chamber and tray components are made from rugged, non-toxic, uv-resistant polycarbonate

Multi-purpose trays conveniently hold petri dishes, test tubes, T C flasks, microtest plates, etc

Chambers can be stacked and interlocked for agitation or storage

And now for the best part The price of the chamber with 3 trays is only $95 · To order or for further information phone or write Billups-Rothenberg, Inc , Dept N-1, P O Box 977, Del Mar, CA 92014 USA (714) 755-3309

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,**1(1975)and **264,**v,11 Nov.(1976).

Rapid effect of change in cerebrospinal fluid sodium concentration on salt appetite	*R.S. Weisinger, P. Considine, D.A. Denton, M.J. McKinley and D. Mouw*	490
Immunisation of guinea pigs and cattle against ticks	*J.R. Allen and S.J. Humphreys*	491
Involvement of a gene on chromosome 9 in human fibroblast interferon production	*A. Meager, H. Graves, D.C. Burke and D.M. Swallow*	493
Sheep fetal haematopoietic cells produce adult haemoglobin when transplanted in the adult animal	*E.D. Zanjani, P.B. McGlave, A. Bhakthavathsalan and G. Stamatoyannopoulos*	495
Evidence of continuous evolutionary change in structures mediating adherence of lymphocytes to specialised venules	*E. Butcher, R. Scollay and I. Weissman*	496
Distribution of fibronectin in the ectoderm of gastrulating chick embryos	*D.R. Critchley, M.A. England, J. Wakely and R.O. Hynes*	498
Insulin-receptor antibodies mimic a late insulin effect	*E. Van Obberghen, P.M. Spooner, C.R. Kahn, S.S. Chernick, M.M. Garrison, F.A. Karlsson and C. Grunfeld*	500
ß-Adrenoreceptors determine affinity but not intrinsic activity of adenylate cyclase stimulants	*L.J. Pike, L.E. Limbird and R.J. Lefkowitz*	502
Acetylcholinesterase like that of skeletal muscle in smooth muscle reinnervated by a motor nerve	*N.C. Inestrosa, B. Mendez and J.V. Luco*	504
Aequorin luminescence during activation of single isolated smooth muscle cells	*F.S. Fay, H.H. Shlevin, W.C. Granger and S.R. Taylor*	506
Light-activated drug confirms a mechanism of ion channel blockade	*H.A. Lester, M.E. Krouse, M.M. Nass, N.H. Wassermann and B.F. Erlanger*	509
Occlusion of K ions in the unphosphorylated sodium pump	*L.A. Beaugé and I.M. Glynn*	510
Highly active cyclic and bicyclic somatostatin analogues of reduced ring size	*D.F. Veber, F.W. Holly, R.F. Nutt, S.J. Bergstrand, S.F. Brady, R. Hirschmann, M.S. Glitzer and R. Saperstein*	512
δ-Aminolaevulinic acid is a potent agonist for GABA autoreceptors	*M.J.W. Breennan and R.C. Cantrill*	514
Correlation of local stability of DNA during melting with environmental conditions	*J. Gabbarro-Arpa, P. Tougard and C. Reiss*	515
Environmental factors affecting the quantity of alcohol dehydrogenase in *Drosophila melanogaster*	*B. Clarke, R.G. Camfield, A.M. Galvin and C.R. Pitts*	517

NICHOLAS COPERNICUS

VOLUME II ON THE REVOLUTIONS

AN ENGLISH TRANSLATION BY EDWARD ROSEN

It is nearly 500 years since Nicholas Copernicus, the father of modern physics, dedicated to His Holiness Pope Paul III, his theories on physics in De Revolutionibus Orbium Coelestium.

Now for the modern academic, unversed in mediaeval Latin, Professor Rosen has produced a new translation, together with a detailed commentary on the complete Latin text.

This is the 2nd volume in a planned 3-volume set of the complete works of Copernicus organised by the Polish Academy of Sciences. Printed and bound to a very high standard, it is a work of great scholarship and art in its own right, and a fitting companion to Volume I, the full-colour facsimile edition published in 1972.

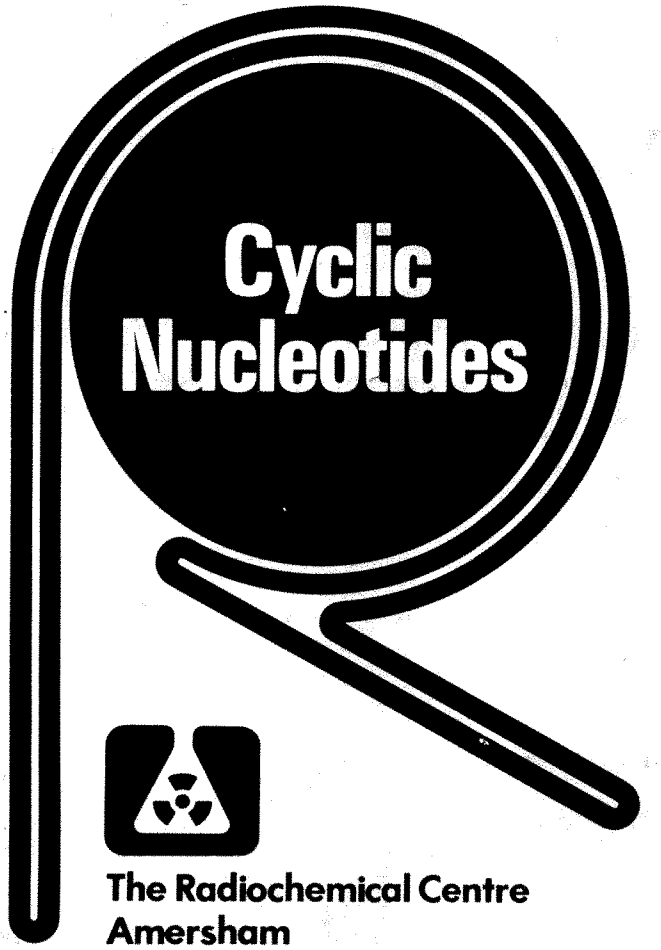
REPRINTS

High-quality reprints of any paper published in **Nature** can be bought in bulk quantity (50 or more).



This service is not restricted to authors.

Typically, 100 2-page reprints would cost £18.90 (£23.50 by airmail); 1,000 would cost £41.35 (£89.70 by airmail). Covers can also be supplied.

Why not write to us for a quotation?

Who participates . . . and how?

SYDNEY BRENNER: The discussion goes that the public should know and the public should decide and the public should participate in all the decisions on what research should or should not be pursued. And we are told that these are not decisions for scientists to take alone in laboratories. What I should like to hear spelt out is: how does the public actually come to participate in these decisions? I mean, we're talking about experimental politics rather than experimental biology here.

ANTHONY QUINTON: There's a saying here, isn't there, *sagesse oblige*. The trouble is that the general public is not in a position to make any sort of decision at all until it is told a great deal by scientists. I think one might reasonably say the existing institutional machinery for the public dissemination of socially interesting or socially relevant scientific activity is rather rudimentary and haphazard and improvisatory.

On the other hand, I don't think I'd like it to be the responsibility of a particular ministry, with civil servants putting in papers. It's just the sort of thing that a Quango might be rather good at doing, where you have a very substantial scientific representation, where scientists would come and talk about their work. A sort of conceptual, theoretical ombudsman in a way.

BBC Radio 3, reprinted in *The Listener*, 26 July 1979.

NIGEL FORMAN, one of the few Members of Parliament with a lively and continuing interest in science and technology, notes the demise of the Commons Select Committee on Science and Technology in this issue (page 443). With the disappearance of one valuable meeting point for scientists, administrators and 'the public', to be replaced by new department-orientated committees in which science is most unlikely to receive as consistent a hearing, it is reasonable to ask whether public understanding of science — or more particularly public understanding of the social issues raised by science — is unacceptably low, as might be inferred from Anthony Quniton's remarks.

What channels are there in Britain for keeping up the links? Obviously there are the printed and broadcast media, with quality ranging from very high to abysmal — but with, of course, relatively few opportunities for two-way communication. There is, sadly, no real British equivalent of the excellent serious American magazines able to devote substantial space to matters of public policy. There is the Royal Society, which has been trying, through its discussion meetings to introduce the occasional large scientific issue to a wide public — but which, too often, flounders on the uncompromisingly technical nature of its lecturers' contributions. There are the British Society for Social Responsibility in Science, the Royal Institution, the newly-formed Science and Technology Association, the Science Policy Foundation and the Council for Science and Society, each trying in distinctive ways to encourage scientists to think beyond the confining walls of their disciplines. There is the Parliamentary and Scientific Committee, an informal meeting point for parliamentarians and top scientists and engineers. There is, of course, a quango already in existence — the Genetic Manipulation Advisory Group, comprised not just of experts but of representtives of the public interest. There is the British Association for the Advancement of Science struggling against formidable odds to inform a wider public about science — including the social questions raised by science. And there is still some parliamentary select-committee activity, because the House of Lords keeps a rather effective eye on EEC science and environmental policy and may possibly broaden its interests in science and technology in response to the loss of the Commons committee.

But does all this activity add up to a scientific and technological community well aware of social issues? And does it produce a large pool of informed citizens capable of communicating easily with scientists and drawing them into debate on these issues? It does not. Part of the reason is undoubtedly that there are too many organisations covering the same sort of ground, looking to the same sources of financial support, calling on the same pool of people for their core support. But this is not the whole story. When scientists have gone out of their way in the past to discuss their work and its implications with intelligent non-scientists, they have too frequently found the response disappointing, both in terms of numbers who attend in the first place and those who are prepared to make the intellectual effort to stick with a subject after a first encounter.

So, with gloomy experiences in the recent past, there is a temptation to keep further efforts in the field to a low level and restricted to a limited number of people close to the interface. This would be a mistake. There is always scope for new initiatives, but they surely have to be done on a substantial scale and have enough long-term commitment that they do not capsize if one venture turns out to be a flop. The most obvious place in which to experiment is the Royal Society. It has adequate meeting rooms, a sizeable secretariat, connections in high places, easy access to a very wide range of scientists, prestige ... Regular, open meetings, not just in London, designed to bring scientists and non-scientists together are surely not beyond its capabilities and could play a major role in raising Britain's painfully low awareness of science. □

US Congress gives go-ahead to Third World institute

LEGISLATION establishing a new Institute for Scientific and Technological co-operation (ISTC) was approved in both houses of the US Congress last week, following the Senate's agreement to drop its previous opposition to the scheme. Although the budget of the ISTC still has to be agreed, the decision means that the US will be able to present the institute as a definite initiative to the United Nations Conference on Science and Technology for Development in Vienna.

Plans for the institute, first announced by President Carter last year and included in his budget request for 1980 presented to Congress in January, had been "derailed" by the Senate in June. The action took the form of an amendment to the Development Aid Authorisation Bill originally offered by Senator Deconcini, who objected to what he claimed was a "new federal bureaucracy" which would duplicate work already being done elsewhere. Meanwhile, the House of Representatives had approved the ISTC proposal, but recommended against the Administration's wishes, that the Peace Corps be made an autonomous agency within the newly-established international development cooperation agency.

The Administration, with a big political stake in the ISTC proposal, was able to watch the two decisions played off against each other during a series of conference meetings between delegates representing the two houses — the formal procedure by which differences are ironed out before legislation can be agreed. After three separate meetings, it was agreed to accept the House position approving the ISTC and the Senate position on the peace corps, thus satisfying the Administration on both counts.

The conference report, which was subsequently accepted by the full House and Senate, also stated that the amount of new money it was prepared to authorise for the ISTC should be cut from the $25 million in the President's request to $23.75 million. Initially the bulk of the institute's research funds will come from the transfer of research projects already underway within the Agency for International Development (AID). The precise budget will not be settled until both houses agree to foreign aid appropriations next month. The conference also agreed to accept the modifications which the House had previously made to the Administration's proposal for the ISTC. In particular, it has strengthened the role of the governing council so that it will have the right to review (although not, as some would have liked, to veto) all projects costing more than $200,000 or lasting more than two years. The new institute will have two main functions: to support research into topics of direct relevance to the developing countries and to help stimulate the development of research facilities within the developing countries.

Pakistan considers uranium enrichment

Pakistan has an ambitious nuclear power programme and, consequently, it is concerned that unless it acquires the capacity to enrich uranium locally, its energy supply will be highly vulnerable.

Two years ago, Canada backed out of the contract it had with Pakistan to provide fuel for KANUPP (the Karachi Nuclear Power Plant which it had already installed) over the issue of whether or not Pakistan was to acquire a reprocessing plant from France. "What do you expect us to do after the experience at KANUPP", said one Pakistani scientist. "If we had not developed the capability of fuelling KANUPP on our own, the 137 MW power plant would have been written-off".

Similarly, a 600 MW reactor being built at Chashma in north Pakistan, received a setback when France backed out of a deal to deliver a reprocessing plant to Pakistan after pressure from the US. Nevertheless, Pakistan's nuclear think-tank forsees many nuclear reactors of either the US light water type or the advanced gas-cooled type being built in the 1980s. Such reactors run on enriched uranium (3% or a little less). KANUPP, the only nuclear power reactor in the country at present, runs on natural uranium.

With the development of the centrifuge technique, uranium enrichment is no longer beyond the reach of the developing countries. Previously uranium enrichment had relied solely on gaseous diffusion. The situation, however, is now changing. In 1977, even the President of the US approved the gas-centrifuge technique and opposed the construction of a large and costly diffusion enrichment plant.

The centrifuge technique appears to have advantages over diffusion methods where the output of enriched uranium needed is small. A centrifuge complex can be built in stages and a start can be made with only a few hundred centrifuges.

Apart from the advantage that the centrifuge technique presents, Pakistan also possesses two other assets over other developing nations. It has about 500 nuclear scientists/engineers, and sizeable uranium deposits in the Dera Ghazi Khan district.

HSE to review safety at Windscale

FOLLOWING the latest incident of a fire at Windscale where five workers suffered low level Cs^{137} contamination, the UK Health and Safety Executive has announced that it will conduct a review of the plant's safety arrangements. A review team consisting of Mr Fen Charlesworth, Senior Deputy Chief Inspector of the Nuclear Installations Inspectorate, Mr Bill Kenney of the Department of the Environment, Mr Stan Gronow from the HSE and a fourth independent specialist to be announced, will investigate safety management, safety surveillance and safety assessment procedures at the reprocessing plant.

The committee has taken the unusual step of announcing ahead of time that it will publish its findings. An HSE official told *Nature* that the large number of incidents at the plant and public concern about the plant's safety have made the HSE want to "let the public see what we are doing about Windscale". According to HSE records the Windscale plant has had 75 incidents since December 1976. Of these, three incidents in addition to the fire are considered major: a still unlocated leak in the B38 silo, a potentially explosive hydrogen build up in the same storage building, and a sump leaking 20,000 curies into the soil earlier this year.

The team will call independent consultants, chosen for specific expertise. They are not expected to include well-known critics of Windscale safety procedures such as Dr Michael Flood and Walt Patterson of Friends of the Earth.

The general investigation has pre-empted a review of the cause of the latest fire leaving numerous questions unanswered. The fire occurred when a fuel disassembly apparatus jammed in a decanning cave. The fire had to be put out manually and radiation escaped contaminating the five workers and causing fallout outside the building. The exact sequence of events is unknown and the questions raised by the incident are central to Windscale safety precautions. These include; how the fire began, why the installed sprinker system failed to put it out, why the fire burned for as long as 45 minutes, why the fire had to be put out with a fire hose by opening access holes in the roof of the cave, how the radiation escaped, whether the workers were wearing protective clothing and how they got exposed. British Nuclear Fuels has refused to comment on the questions. "We are not prepared to answer questions which will cut right across the internal inquiry presently underway," an official told *Nature*. When complete the report will be released to the local liaison committee.

Comecon tackles the energy crisis

Vera Rich explains how the Eastern bloc is coping with the rising price of oil

Recent oil price rises throughout Eastern Europe, coupled with Romania's unprecedented demand that tourists from other Comecon countries must purchase their petrol for hard currency, at first glance accords ill with Mr Kosygin's remarks at the Comecon summit at the end of June. In fact there is no contradiction. What Mr Kosygin promised for the next Five Year Plan (1981-86) was a 20% increase in energy supplied by the Soviet Union to the bloc, not specifically oil.

Commenting on Kosygin's speech, a TASS reporter quoted Dmitrii Mendeleev, discoverer of the periodic table, that "to use oil or banknotes for heating comes to about the same thing". While the West has based its economy on oil, he continued, the Soviet Union has "harmoniously" developed all fuel and energy branches of the economy: coal, shale, hydroelectricity and nuclear power, as well as the oil and gas fields.

Kosygin's statement of existing Soviet energy supplies to the Comecon allies is impressive: during this Five Year Plan, some 370 million tonnes of oil, 46 million tonnes of oil products, 88 million cubic metres of gas and 64 million kW-h of electricity. But the official communiques of the meeting stressed that from now on the extraction of oil and gas would continue to increase, but would be devoted primarily to the needs of the chemical industry. It seems likely that a major proportion of any increase in energy supplies from the Soviet Union will take the form of electricity. A massive plan to step up generating capacity in the USSR is already under way. From 1980, all increases in the European part of the USSR will be nuclear; east of the Urals, a network of thermal power stations will be brought into the grid, fired by lignite, of which there are abundant local supplies.

All Comecon countries, with the exception of the Soviet Union, are now net importers of petroleum. Even Romania, whose role as a former major oil producer is commemorated by an oil rig in the state coat of arms, has to import a certain proportion from the hard currency market. Although energy is one of the specific sectors selected for the "long-term target-orientated" Comecon integration programmes approved in 1976 (for the period 1975-1990), Soviet oil prices to the other Comecon countries are calculated from the average world price over the last five years and reassessed each year. Moreover, Soviet-exported oil accounts for only 80% of the other members' demands: the rest they must purchase on the world market.

Furthermore, the long-term availability of Soviet oil appears to be in some doubt. All official sources unequivocally repudiate the CIA predictions of an impending Soviet oil crisis. Shortfalls are attributed to the technical difficulties of bringing the East Siberian fields on-stream, and the consequent depletion of the West Siberian fields more rapidly than planned. Occasionally, too, "anti-social manifestations" among the oil workers may be blamed for a temporary deficit (*Bakiskii Rabochii* 1 June, 1979).

Russian pipeline: the oil will keep flowing, say Soviet officials

Nevertheless, nuclear power is seen as the mainstay of the future energy needs of the bloc, and the construction of nuclear power stations is a top priority in all member countries except Poland. Here the still abundant coal reserves make it possible to defer the introduction of nuclear power on a commercial scale, and the one nuclear power station so far scheduled (a joint venture with the Soviet Union) is seen, in the words of one energy expert, as "a pilot project for the Polish situation".

Socialist planning, it appears, leaves no room for an environmental lobby against nuclear power. A recent Hungarian publication stresses that "in the philosophy of socialism, environmental detriments may present no limitations to the welfare of society. The growing demands of society must be satisfied, since failing to do so would contravene the basic principles of socialism".

So far, only the dissident "Document 22" of the Charter-77 movement has dared to question the validity of the nuclear solution. By 1990, according to the latest agreement, the nuclear generating capacity of Comecon will have been raised from the present 15-18 million kW to 150 million kW, 37 million kW of which will be sited outside the Soviet Union.

Meanwhile, in spite of the agreed integration programme, the search for home-based fuel sources continues throughout the non-Soviet members of the bloc. Poland has a long-standing programme of coal mine modernisation, including a sophisticated research programme into the causes of mine-gas explosions. A country-wide geological survey for oil and gas resources has produced an impressive set of maps of the various strata, and is now proceeding to the field-work stage. No detailed interim results are available, although one geologist connected with the survey told *Nature*, last autumn that there were "positive indications". The survey is being continued offshore by an international consortium of Poland, East Germany and the Soviet Union.

Romania, too, is looking offshore. The new draft programme for research and development to be submitted to the forthcoming congress of the Romanian Communist Party stresses the need for offshore exploration and exploitation. Not only will this include mineral wealth, but the possibility of building a pilot wave-powered generating station is also under consideration. Full use of the hydroelectric potential of the Danube is a target for 1990, lignite and shale mining will be intensified, and a number of more exotic schemes — "biogas", the extraction of hydrogen from water, and the use of geothermal energy — are to be given serious consideration. By 1990 it is intended that the country should be self-supporting in energy, while the average energy consumed per 1000 lei of industrial output is intended to fall by at least 40%.

Czechoslovakia is looking closely at the home: modern flats, said the Director of the State Power Directorate recently, consume about 50% more heat than the norm, due to poor construction and installation. Yugoslavia (not a member of Comecon but closely linked with the bloc) has already decided not to build any further oil-burning power stations and to upgrade its neglected coal and lignite resources. Finland, likewise partially dependent on Soviet oil, is seriously considering the energy potentialities of scrub timber grown on marginal land. Hungary is showing a renewed interest in coal, and the latest updating of the UK-Hungarian Joint Commission on Technological Co-operation agreed last

0028-0836/79/320437-01$01.00

©Macmillan Journals Ltd 1979

month includes a new cooperation project on coal technology. Bulgaria, while so far urging no major changes, is cautiously contributing to the energy debate by publishing statistics of kW-h of lighting saved this year by "summer time".

Meanwhile, East Germany, although claiming that, in spite of the harsh winter conditions, planned production of electric power was "achieved as a whole after the first six months", did not allow the temporary setback to the economy to be entirely attributed to meteorological conditions. In June, a result of "shortcomings in management, especially in the ministerial sector for coal and power", Klaus Seibold, the Minister of Energy, was dismissed from office. □

Spanish scientists have to fight for survival

Research in Spain is suffering from a lack of direction and funds. M Vicente, a Spanish biologist, reports on a recent meeting of scientists to discuss their plight and Emilio Munoz (below) reports on one ray of hope — the setting up of a new research ministry.

Uncertainty of direction, lack of promotion opportunities and no guarantee of long-term finance: these are the crucial problems that bedevil scientific research in Spain. They were given a public airing last month when biology and biomedical researchers met under the auspices of the CSIC (Consejo Superior de Investigaciones Cientificas). The scientists' intention was to test the reaction of the newly-created Ministry of Universities and Research (see below) to their complaints, and what emerged from the researchers amounted to a cry for survival.

The meeting had no difficulty agreeing that research policies were needed related to Spain's particular requirements. But they could not decide whether this was best approached through basic or applied research. One speaker said biology in Spain had concentrated on basic research for the past 15 years and all applied approaches had been treated as secondary. It was not surprising, he added, that there were no links between society and research and that, as a result, society was indifferent to the present scientific crisis. Other speakers defended basic research and argued that they were doing enough for society by teaching young scientists in the universities.

The second major theme of the meeting was that the country's scientific researchers were not only too few in number but also too old. The average age of Spain's scientific community was said to be around 48 and this restricted the job opportunities for young scientists. The number of young PhDs nearly doubled every four years but only one in five had a job related to his specialisation. Several causes were given for this situation, all with the same roots: the absence of long-term planning and the lack of interest in research.

Spain's scientific development during the 1960s happened at the wrong time and went in the wrong direction. The economy caught up with other developed countries, but largely because of imported foreign technology. A 10%-a-year increase in public sector research staff was intended to accompany economic growth but never came into effect. Researchers in the private sector are even fewer and their work is limited to quality control. All these problems have now been aggravated by economic difficulties, so that Spanish research is coming of age at the worst possible time.

For scientists, the finance situation could be the most worrying of all. Because of its lack of social impact, research is not in the official list of priorities. Half way through the present year, research groups are spending the money assigned to them last year. No official programme of grants has been issued yet for next year. Unless urgent measures are taken, and experience of Spanish bureaucracy makes it unlikely that they will be, most scientists will have to stop their work early in 1980. Even strong groups, such as those in the Molecular Biology Centre in Madrid.

A secret three-year government plan to finance research was drafted a year ago. Its text is not known, raising suspicions among scientists that it will channel money to the increasingly overcrowded universities in which research has been so difficult that it tends to be the activity of a few dilettantes. They are afraid that a decision to transfer them to academic jobs will irreversibly damage their research activities. □

Will the new research ministry fill the vacuum?

SPAIN has established a Ministry of Universities and Research — a move which has been welcomed by the scientific community. Scientists have felt that the lack of an effective government science policy has been paralysing efforts to build a new structure for research in Spain around the re-constituted Cosejo Superior de Investigaciones Cientificas (CSIC), and they hope the new ministry will fill the vacuum.

The Ministry of Universities and Research has been created by splitting the functions of the former Ministry of Education and Science, in which science had become submerged in the complicated problems of education. However, there are still fears that hopes for specific research proposals may again be disappointed. The government has not yet presented its research programme, so the reasons for the creation of the new ministry are unclear. And there is still a lack of communication between the scientific community and society. No national debate has taken place in parliament on this subject, although various sectors in the country have been demanding such a debate since 1977.

The need for a new ministry was established more clearly when the new statute of the CSIC was first put into practice. It was published in January 1978 and came into force the following June. It included a new system of government for the CSIC with the participation of collegiate bodies as advisory organs, and responsibility for the economic and scientific fields through the Scientific Council and Economic Council. This made real change in the CSIC a possibility. As with all the Spanish organisations during the time of the autocratic regime, CSIC had been conducted without any clear intent. However, the councils suffered many difficulties during their first months, due to a lack of scientific policy. The absence of any sign of a specific scientific policy has prevented a rational reorganisation of CSIC.

The reorganisation attempted by the CSIC so far has been mainly bureaucratic and administrative and is thus running the risk of becoming neither lively, dynamic nor relevant. However the Scientific Council of CSIC has made imaginative efforts to amend its organisation. A document on the general trends of scientific policy in CSIC has been elaborated, which considers as fundamental that the activity of CSIC be adjusted to the needs of Spanish society and to the manpower and material resources of CSIC itself. The budget for 1979 allows 100 pta. (less than US $2) per day per research worker for expenses of nonrecoverable material — and this represents a significant improvement over 1978!

Within the limited possibilities offered, CSIC has strived to overcome one of its main criticisms — its isolation from other research institutions. It is stressing agreements with universities and research institutions with the ultimate goal of resolving the existing academic power struggles. The Scientific Council of CSIC is trying to cooperate with the new Ministry of Universities and Research and recently asked for an interview with the minister with the aim of establishing contacts. □

news in brief

Five French unions oppose CNRS reorganisation: Plans by the Giscard d'Estaing government to reorganise the Centre National de la Recherche Scientifique, France's national research council, have been met by opposition from five of the trade unions involved, according to recent reports in *Le Monde*. Mr Guy Hermier, a deputy from the Bouches-du-Rhône constituency, vice president of the national assembly and a member of the political bureau of the Communist Party, has called for a national debate on the future of the CNRS to be preceded by expensive consultations with the scientific community. In a letter to the Prime Minister, Hermier accused the government of giving up control of research to industry.

The reorganisation plan proposes a reduction in numbers of representatives on national CNRS committees, the addition of representatives from industry and the exclusion of technicians and administrators who are currently represented. The streamlining of the council and the involvement of representatives from outside the inner circles of the CNRS is seen by the government as an important move to decentralise research and to make results more accessible to the needs of French industry.

BSSRS criticises HSE on MMMFs: The Work Hazards Group of the British Society for Social Responsibility in Science has questioned a recent UK report on the hazards of mineral fibres used for insulation (19 July page 183). Although welcoming the tripartite (industry-trade union-government) report from the UK Health and Safety Executive which warns that "it would be prudent to regard these fibres with suspicion", the Work Hazards Group raises "considerable" objections to some of its conclusions. In particular the report is criticised for underplaying the risks to the domestic householder, 'minimising the risk of bronchitis due to high dust levels and inadequate dust-exposure and emission controls. Citing the known dangers of respirable dusts and fibres below 3.5 microns in diameter to the air sacs of the lungs, the Hazards Group criticises the classification of mineral dusts as nuisance dusts. "We know from asbestos that the small fibres cause pneumoniconiosis and mesotheliomas" says Dave Hayes of the Hazards Group. "And all mineral insulation materials contain these respirable fibres." More generally, the group is critical of the Department of Energy for promoting mineral fibres for the do-it-yourself home insulation market without "due regard for the hazards involved".

The Work Hazards Group recommends a sharp cutback in the production of small fibres (which it says are unneccesary for insulation), strict controls on home and industrial use of dust-causing insulation materials, notification to home owners that a "good" respirator should be used and that trade unions should keep their own medical records for workers at risk. Recommended substitute materials are insulation board, vermiculite and cellulose newsprint used with a good respirator. *Mineral Fibres. British Society for Social Responsibility in Science, 9 Poland St, London W1, 13p.*

Three Mile Island citizens panel dissolved: The shortest governmental advisory committee in many years was dissolved on 25 July without holding a single meeting. Four weeks ago, the Kemeny Commission which is investigating the accident at the Three Mile Island nuclear plant in Pennsylvania, appointed a nine member citizens advisory board to give it some "outside input". The Commission, apparently, got more than it bargained for when the panel demanded copies of all staff memoes, draft reports and work plans, access to all federal and industry documents subpoenaed by the Commission and depositions taken by the legal staff. In addition the panel demanded the opportunity to review lists of witnesses, to demand additional witnesses and to criticise and review the final report before it went to the White House. The Commission had envisaged the citizens committee taking a more passive role by answering nine questions put to it. "They wanted to be inside and we felt that was unacceptable" said Barbara Jorgenson, press officer of the Commission. At a meeting on 5 August the Commission voted to circulate the questions to the groups represented by the original nine panel members and to solicit suggestions and answers from an additional 200 public interest groups.

Life or death of an observatory: The Centre for Geodynamics and Astronomy, near Grasse in Southern France, was planned to co-ordinate all observational activities in the fields of positional astronomy and geophysics. The first interferometric star observations were obtained last year using a 30m baseline Michelson interferometer. But only 6.5 km away, a quarry and stone-crushing operation has created dust that will diffuse the night light from the coastal towns which will make very faint objects completely invisible. The large Schmidt optical telescope, installed last year, now might not be able to observe more than just a few percent of the interesting stars. Another problem is vibration from quarrying activities which disturbs high precision optical and long-baseline interferometric measurements. Appeals to the local authorities have failed and the CERGA has petitioned the appropriate ministry. But will the case be taken up in time, before the site is permanently ruined, by government bureaucracy?

From the staff of la Recherche

USSR higher education shows sharp regional discrepancies: A working note issued by the German Rectors Conference shows that higher education in the Western regions of the USSR continues to outstrip that in the other republics. The western republics lead in higher education with 200 students per 10,000 inhabitants. This is followed by the Baltic republics with 185, the Caucasian republics with 175 and the central Asian republics with 159.

The rate of increase of higher education also favours the western region with the number of students increasing relative to the population by a factor of 2.58 since 1966 while the Caucasian republics brought up the rear with an increase of only 1.06. The Rectors conclude that the discrepancies are small "considering that the Central Asian Republics can be regarded as developing areas." *CRE-INFORMATION No. 46. Standing Conference of Rectors and Vice-Chancellors of the European Universities.*

Solar activist to head research institute: The US Department of Energy has appointed Denis Hayes, a prominent leader of the environmentalist lobby and currently a senior research fellow at the Worldwatch Institute in Washington, as new director of the Solar Energy Research Institute (SERI) in Golden, Colorado. Hayes, one of the main organisers of last year's international sunday, will at the age of 34, become the youngest director of a national research laboratory. He succeeds the current director, Dr Paul Rappaport, who has headed the institute since it opened , and who will remain at the institute as distinguished scientist.

"My goal is to make SERI the most exciting and effective energy research organisation in the world," Hayes said last week. "The institute has a staff of first-rate analysts already thinking through the strategies and research requirements. Now its time to get those programmes moving".

Yoshimura has to leave Britain: Dr Tetz Yoshimura, the Japanese mathematician, has lost his fight to stay in Britain. He left for the continent earlier this week, a few hours ahead of a deportation order. Dr Yoshimura told *Nature* that he hopes to wait in "a country with less stringent immigration laws" for an invitation to a new academic appointment "somewhere in the third world".

'Always on tap, never on top'

Government scientists this week called off their industrial action after settlement of their prolonged pay dispute. **Joe Schwartz** reports on the scientists' attitudes towards the strike whose success took both union and management by surprise

"WE'VE ALWAYS been known as a non-militant union. I guess the Civil Service Department thought we would stay that way", declared a local committee member during the strike by the Institution of Professional Civil Servants. The 104,000 members of the IPCS amazed the public and fellow trade unionist with five weeks of action to back up their pay claim against the government.

To outsiders, the scientists and technologists in the UK's Civil Service are unlikely candidates for militant industrial action. Their union, one of seven in the Civil Service, only affiliated to the Trades Union Congress in 1976 by a vote of 57,000 to 38,000; the minority argued that trade union affiliation was "unprofessional". But strength of feeling built up through a series of skirmishes with their Civil Service bosses dating back to 1974. One member voiced the general feeling: "People think that civil servants are advisers to ministers. We're not. We're ordinary scientists and technologists who are sick and tired of being taken for a ride. Whenever there is money to be saved, the government tries to take it from the scientists".

With this growth of feeling, the only question earlier this year was how the IPCS's 25-member elected national executive and its full-time office staff of 30 would organise themselves for the annual pay talks with the Civil Service Department in April. "In fact, we organised very poorly," says Bill Brett, assistant general secretary of IPCS. Brett, a trade union organiser for 15 years in four different unions (including six years with Clive Jenkins of the Association of Scientific Technical and Managerial Staffs), expected that it would take a dramatic move on the part of the CSD to galvanise the membership. The CSD obliged. They refused to recognise a promise given the previous year that scientists' pay rises would be linked to civil servants' in the administrative grades. After granting 25%-45% to the administrators, the CSD offered only 18% to the scientists.

Scientists and technologists saw it as the culmination of what some alleged was a campaign in the CSD to downgrade the scientists. Tired of being "always on tap and never on top", they met in conference and instructed their leadership to organise industrial action.

The union drew up a battle plan of half-day strikes, working to rule, one-day demonstrations and the critical selective strikes that were to bring work in many government laboratories and defence establishments to a halt. The plan was put to the members at a series of meetings throughout the country. "We spoke to 50,000 members at about 25 evening meetings of from 500-2,000 people over a period of two weeks", says Brett. "We received an overwhelming mandate to go ahead."

For scientists at the Central Veterinary Laboratory in Weybridge, the strike call gave them the chance to use the experience gained two years earlier when an "informational picket" turned into a fully-fledged strike in support of a claim for an outer London pay allowance that had been granted to neighbouring laboratories.

The Weybridge laboratory does research on animal diseases. It is responsible for reviewing the quality and effectiveness of commercially produced drugs and it operates a P4 containment facility for diagnostic work on rabies. Work at the laboratory was brought to a halt when the local IPCS committee pulled out two of its supervisors from the laboratory's steam room. Members of the Transport and General Workers Union refused to work without supervision, and the laboratory's five high pressure boilers were shut down, cutting off heating, autoclaves and distilled water facilities. Eight more members were called out and a picket line set up which lorry drivers and post office workers refused to cross, thus halting the delivery of supplies and samples to the

Digging in: Striking scientists at the Laboratory of the Government Chemist in London combined three weeks of picketing with some voluntary community work, clearing up allotments for old people. Leaving one person on the picket line, the strikers kept themselves busy on a daily work brigade.

0028-0836/79/320440—01$1.00

©Macmillan Journals Ltd 1979

laboratory.

The picket was not total, however. IPCS members decided they would give exemptions in cases of safety and public health. Thus, at Weybridge, operation of the P4 containment facility was guaranteed, as were deliveries of liquid nitrogen to maintain the laboratory's reference cultures of viruses, parasites and bacteria. Applications for exemptions went through the elected local committees; doubtful cases were passed on to the union executive committee.

At the Laboratory of the Government Chemist in London, a management request to allow gas deliveries through was refused. "All they wanted to do was to continue as usual. There was no question of safety", explained Arnold Pinder, secretary of the LGC section. Chemists at the LGC found that they too tried at first to carry on as usual. "Your first inclination is to keep working. You don't really want to strike and you look for ways to get around it. We had no chemicals, no water and no service. So we looked for other things to do", says Pinder.

A significant feature of the IPCS strike was the solidarity shown within the heterogeneous membership. Scientists stayed out on strike for three further weeks in support of the technologists after their own pay claim was settled. Again the Civil Service Department appears to have underestimated its adversary. "It was so obvious", says an LGC member. "First they split off the union with the least militant reputation and the most split membership. Then they tried to divide the scientists from the technologists, and then they tried to settle with the younger scientists at the expense of senior staff by offering the first two steps of the rise only." The tactic unified rather than divided the membership. "The CSD did at a stroke what the IPCS has been trying to do for years."

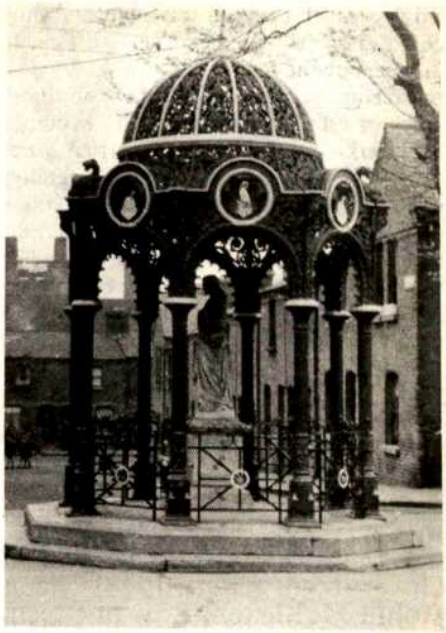
The IPCS action achieved a number of specific results and one important general result. The scientists are to set the same pay rise as their administrative colleagues this year. The technologists, however, feel they have a basic principal to settle about their status and comparability. This is now to go to a conciliation procedure.

But most importantly, IPCS members have realised that they can exercise effective industrial muscle. It has surprised both union and management. Researchers are reluctant to strike and have difficulty in seeing how withdrawal of their labour can be effective. Scientists in the IPCS have learned how to do it. This will change the complexion of all future pay negotiations. As Arnold Pinder put it: "We don't like to strike. But no one will listen to you unless you strike. You have to show your power before they'll listen." □

Ireland, land of priests . . . and engineers

Robin McKie compares the high status of the Irish engineer with the low status of engineers in Britain

THE realisation that Britain's manufacturing industry is far behind our competitors in terms of flexibility, sophistication and output has been forced upon the nation in the wake of its decline as a major commercial and financial force. And certainly any understanding of the problems which afflict the country's technological capabilities requires some form of detailed comparison with the performances of our closest competitors.



Indeed, in the case of our nearest English-speaking neighbours, the Irish, the contrast is striking — and decidedly unflattering. Last year the gross national product of Ireland expanded by 5.5%, almost twice the European average; manufacturing investment increased by 20% and manufactured exports rose by more than 20%. This year, industrial output is expected to rise by 11% — compared with 2.25% in the UK! This has been achieved by attracting a vast amount of foreign investment, mainly by permitting companies to make tax-free export profits until 1990.

It may allow large amounts of money to slip out of Ireland, but it has also succeeded in attracting more than 750 manufacturers — including major microelectronics, drug and oil companies — in the past 20 years, produced fixed assests worth £1500 million and in 1977 alone saw the creation of 24,000 new jobs.

In a sense, these measures were forced upon Ireland — a nation which has never been rich or prosperous. However, it is hoped that eventually the resulting financial regeneration and accompanying technological infrastructures will help transform the country into a major independent industrial force. And certainly "the Irish miracle" represents a remarkable achievement and indicates the country's critical recognition of the importance of high technology.

This last factor reflects the influence of scientists and engineers in Ireland and their importance within industry and government. In Britain, the engineer and technologist is all too often relegated to a minor, supervisory role inside a company, while his Irish counterpart wallows in high status and recognition.

As Professor P Leahy, dean of engineering at University College Dublin, put it: "Over here, an engineer is looked upon as someone like a doctor or a priest".

Religious shrine in Dublin — also a city of developing industry

And a more striking illustration is provided by the fact that the chief executives of Ireland's broadcasting corporation, transport system, electricity board and many of its investment banks were all originally engineers.

This obvious high achievement rate has had the effect of encouraging the very best students to take up engineering. For instance, in 1977, 15% of entrants to University College Dublin's engineering school had scored 30 or more points in the national school leaving examinations of Ireland. This compared with 7% of those going into medicine, 0.72% into law, 0.41% into science and 0.19% into arts.

This is a remarkable contrast to Britain where often the lowest qualified students form the largest proportion of engineering students. For instance in the period 1973-75, a total of 42% of students taking engineering at universities had worse than the equivalent of three Cs at A level. In science the proportion was 34%, in medicine 26%, and in social, administration and business studies, only 24%.

For the Irish, this concentration of talent has resulted in engineering schools becoming the prime recruiting grounds for chartered accountancy firms and investment banks who sell employment as a major route into management. (Indeed, many of the academic staff at UCD's faculty of commerce also have engineering first degrees.) And in this way an appreciation of technological matters becomes embedded in the fabric of Irish management and industry.

However, the reason for the original high status of engineers in Ireland is less easily defined, although it is closely connected with the industrial growth of the country and related educational routes.

In Britain, a rapid industrial revolution

0028-0836/79/320441—01$1.00

©Macmillan Journals Ltd 1979

led to a quick demand for engineers who could not be supplied in sufficient numbers by the few existing university departments. So most rose from shop floor workers and craftsmen to become engineers — a process that carried little prestige. But in Ireland — which generally escaped the rigours of industrial revolution — most engineers were civil engineers, with university degrees, who provided roads, bridges and other services for the community and carried a corresponding high status.

Indeed the pervading nature of the differing prestiges of Irish and British engineers is explained by the fact that in 1958, 95% of those achieving engineering status in Ireland did so through university degrees. In Britain, the proportion was still only 39%, the rest achieving chartered status via part-time exams set by the professional engineering institutions. Only in recent years has Britain approached Irish levels for university educated engineers. For instance, in 1974, the figure had reached 90% in the UK, and 93% in Ireland.

Thus a picture can be seen of an original, well-established prestige for engineers in Ireland, leading constantly to better students and eventually to an even higher status. And certainly a thorough confidence in its engineers and technologists, combined with its recent industrial re-birth, indicates a strong financial future for Ireland.

It is then all the more vital to have the right quality of technical manpower to sustain this industrial growth. As Matt O'Donovan, of the Institute of Engineers of Ireland, stated: "It is important that we are training not just for existing industry but to initiate new industry".

It is this last capability that is particularly absent in Britain at present and which must be restored through the proposals of the Finniston committee of inquiry into the UK's manufacturing industry. However it is hard to see how it can find a way to cut through effectively the damaging spiral of engineers' low status, producing poorer levels of student intakes and eventual graduates, and resulting in even lower status for engineers. □

How industry lost an enthusiastic engineer

Robin McKie tells how one technologist's enthusiasm and ambition turned to disillusionment

For Barry Francis, engineering was his only choice of career since the age of nine. It seemed an obvious selection for a youth fired by an early enthusiasm for constructing crystal radio sets and who eventually ended up building hi-fi systems as a hobby.

So after he took O and A levels at Goring Hall, Sussex, he entered Middlesex Polytechnic for his main engineering course and later transferred to Manchester University for a postgraduate diploma in semiconductor electronics. Then in 1969, Barry moved to industry where he began work as a research engineer for Hawker Siddeley at Hatfield.

And almost immediately disillusion set in. "I discovered rather quickly that I would not be pushing back the boundaries of discovery every week. Instead I found myself working on projects that would not come to fruition for 10 to 15 years", he said.

Although the work — designing special instrument displays for vertical take-off jets — provided reasonably fulfilling employment in a limited fashion, it was also clear that the aircraft construction industry was far from healthy. So, with no immediate job satisfaction and no obvious career path, Barry left Hawker Siddeley after only 18 months and moved into mainstream engineering.

At Control Systems, Uxbridge, he was appointed a senior research engineer jointly in charge of a project team of 15 technicians, programmers and engineers who were designing a small business computer to control payroll, invoicing and other office chores for companies of up to 100 employees.

Sadly, although the work again was reasonably fulfilling, disillusion quickly set in once more. A particular problem lay with the firm's controlling company which eventually seemed to lose interest in the project and the team found itself increasingly pushed lower and lower on lists of priorities.

However, more importantly, Barry believes that although the project was a resonably modest undertaking, it required more in terms of human resources than the company could then provide.

These experiences, plus involvement as a writer for engineering journals, led 34-year-old Barry to the view that a major flaw in UK industry is its amateurishness. This is not the particular fault of its exponents but there can be little doubt, he feels, that British scientists, technologists and engineers have a poor feeling for industry.

And a major portion of the blame must lie with UK universities and polytechnics. "My own education did not in any way prepare me for industry's requirements. There was no design, management or marketing training — and these are crucial for you cannot just build a piece of equipment in isolation without knowing if there is a need or a sales potential for it. Really, at university and college, we were just being prepared as glorified technicians".

Generally Britain can be seen as a nation that cobbles things together to produce a solution under pressure. Often budget constraints can help to find more effective production methods but all too frequently initiatives are lost to other countries who are capable of more adventurous and stylish marketing and design systems.

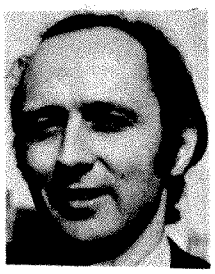
After his two depressing experiences in inudstry, Barry left to be a writer and associate editor for various engineering magazines before later moving on to his present occupation as a public relations consultant. And from his story it is hard to avoid the view that British industry, because of its very make-up, lost someone of ambition and drive who is now unlikely to return. "In a sense I cannot move back at the moment without having to make a big financial sacrifice. In fact, if I went into industry again, I reckon my income would be halved."

This view has often been endorsed by various studies of engineers' conditions in industry. For instance, Peter Lawrence, of Southampton University's engineering department, recently produced a paper which showed that salaries in the UK were greatly below the levels of those in Germany. In 1976, the average salary for an engineer in the UK was £5510 while in Germany it was £12,119 — and at that time the cost of living was only 36.4% higher than in Britain.

Similar discrepencies in awards exist in most other European countries, including Ireland. As Professor Scanlon, head of University College Dublin's electrical engineering department put it: "I can give more to a PhD student in Ireland than industry gives as a salary in the UK".

Of course poor salaries reflect the low status of engineers in Britain — a view backed by Barry Francis. "Not enough bright kids are going into engineering", he said. "They see lawyers and doctors living well and decide to follow them.

"However once you have put this right and have raised the prestige of engineers, the bright children will start coming in, and then we'll eventually get better British products and an improved industrial performance".



But even if conditions were improved, there would still be difficulties in attracting the return of former engineers such as Barry Francis. All too often, these people find their conditions and trainings badly out of date and discover there is no system for updating engineers in recent technological developments. Proposals — such as one-month university courses — are now being considered by the Finniston committee and the Science Research Council is also set to launch a trial project on these lines.

Only when a total package of proposals on these lines is implemented can Britain then hope to attract the talent and ability needed to restore its technological and industrial strength. □

Sadly missed: a key contributor to science policy

Nigel Forman MP mourns the passing of the House of Commons Select Committee on Science and Technology

IT IS not just those of us that had the good fortune to serve on the Select Committee on Science and Technology who regret its demise. There must be many others outside the House of Commons who recognise the valuable contribution which it made to a wider understanding within Parliament of certain aspects of science and technology and to the quality of some government decision-making.

Since its establishment in January 1967, the Select Committee investigated a wide spectrum of subjects, ranging from nuclear power to coastal pollution and from carbon fibres to computers. It was chaired and guided by two distinguished politicians, Arthur Palmer from 1967-70 and again from 1974-79 and the late Airey Neave from 1970-74. There was also a sensible degree of continuity in its relatively small but enthusiastic membership.

It is hard to say exactly how much influence was wielded by the committee, because government departments are not in the habit of revealing to the public the various stages of their decision-making procedures and in our constituion ministers claim sole responsibility for the decisions which are actually taken. However, the record shows that the committee's 1969 report on the UK nuclear power industry which proposed the establishment of an Atomic Energy Board, was eventually followed by the Atomic Energy Authority Act 1971; that the 1971 report on population policy which called for the establishment in government of a special population office, was followed by the creation of the Population Panel; and that the 1974 report on energy conservation was eventually followed in December 1977 by a substantial, if belated, package of energy conservation measures which included some of the recommendations made by the committee.

In other cases, although the government of the day initially reacted in a defensive, even hostile, way to some of the committee's recommendations, subsequent events proved them right or led government to reconsider its earlier policy response. One example is provided by the way in which the last government's initially negative response to the committee's advocacy of alternative sources of energy in its 1977 report was eventually transformed into a more positive view of the need at least to explore the technical possibilities in this area and to do so with the support of adequate R&D funding. Another example is the way in which the Departments of Environment and Transport eventually came to accept the need for the Planning and Transport Research Advisory Committee to include in its terms of reference and its annual report a specific account of R&D work on advanced ground transport, something which had been rejected by government in its initial response of August 1974.

As for the work in progress at the time of the committee's demise, it is impossible to tell yet whether or not the uncompleted investigations into recombinant DNA research and developments in small passenger car engine technology will be pursued by the relevant "departmental" Select Committees which are to take its place. With any luck this will happen and a great deal of useful evidence will not have been wasted. Both these investigations exemplify the tendency of the Committee latterly to balance its work on short-term subjects — such as filament and discharge lamps or the lessons of the Eleni V disaster — with more important long-term work on emerging technologies for the future which may have significant benefits and costs for our society in the 1980s and beyond.

Now that the committee is no longer in existence, it is possible to form a clearer assessment of just what will be missed by Parliament, the press and the general public. Members of the House of Commons will miss the opportunities which the committee provided for consideration of important scientific and technological issues which by dint of their scope and complexity, are bound to transcend departmental boundaries. Recombinant DNA research and the wide-ranging implications of innovation, R&D in Japanese science-based industry are two typical and important examples.

Journalists will miss the platform which the committee provided for the public airing of important questions which are not otherwise debated with any frequency or in any depth in the normal proceedings of Parliament, whether in the Chamber or in legislative Standing Committees. The general public will be deprived of a useful Parliamentary mechanism for encouraging at least some of their elected representatives to look beyond the inevitably short-term horizons of contemporary politics. This last consequence is perhaps the most severe blow, since it is now more important than ever to preserve and, if necessary, create institutional mechanisms which allow arguments about social time preference and encourage the broadest possible cost-benefit analysis to be undertaken across the whole spectrum of contemporary science and technology.

Of course, in many ways the influence of the committee will live on through its *alumni*, like Neil Macfarlane, the junior minister with responsibility for science, who now find themselves in influential positions in government, and through its example in seeking to tackle a wide range of scientific and technological issues which will not go away just because it no longer exists. Furthermore, it is not as if there are not other laudable institutions of these issues. There is the well-established Parliamentary and Scientific Committee which has played a valuable role since its inception soon after the Second World War. There is also the Council for Science and Society which deserves to find continued support for the useful work which it does in attempting to bring scientists and laymen into a state of greater mutual understanding.

However, the fact remains that the peculiar dual role of the Select Committee as an educator of Members of Parliament and an investigator of issues which would not otherwise be the subject of Parliamentary scrutiny, will be difficult to ascribe to any one of the "departmental" Select Committees within the new system recently endorsed by the House of Commons. It must, therefore, become an important objective of those concerned with these matters in the new Parliament to meet this requirement by other means. □

Select committee considers GMAG

THE final report of the Select Committee on Science and Technology, released last week, is the result of the committee's recent investigations into the "public safety and public policy" issues of recombinant DNA.

In a brief summing-up of the evidence taken, the report expresses concern at the way in which the Genetic Manipulation Advisory Group handles notifications of industry's intentions to work with recombinant DNA. Under present arrangements, members of GMAG with potential industrial interests and those who have not signed a confidentiality agreement, withdraw from discussion of notifications by industry. The Select Committee disapproves that an advisory body "set up to safeguard both workers and the general public, should have apparently first and second class members". The report also expresses "surprise" that the Department of Education and Science (DES), not the Department of Health and Social Security (DHSS) is responsible for GMAG. It is concerned that the strong position of UK researchers and companies should not be hampered by unnecessary regulation. International safety standards also "appear to be desirable", it says.

correspondence

Mongolian science

SIR, — In connection with the interview with me, by Vera Rich in *Nature* (28 June, page 754) I would like to ask you to publish the following explanation.

When Vera Rich visited me in Warsaw in October 1978, she was astonished to learn from me that there is a Museum and Palaeontological Laboratory in Ulan Bator, with a group of competent Palaeontologists, some of a very high standard.

I was shocked when I read what she published in *Nature* some 9 months later — an article with ironical remarks about the scientific relationships between the CMEA countries (Comecon in Vera Rich's wording) and about Soviet science; and containing misleading information, for example that R. Barsbold's artile (28 June, page 792) is based on materials from the Polish-Mongolian expeditions, while in fact it describes the specimens collected by the Soviet-Mongolian expeditions.

The unacceptable side of her article is the perjorative and condescending tone in which she writes about Mongolian science and scientists. As her article is written in a form of an interview with me, it makes me look disloyal to the people with whom I have been co-operating for years. I have never described my Mongolian colleagues in a derogatory way. What I have done was the opposite, but this apparently did not fit Vera Rich's ideas about Mongolia.

As a result of this interview co-operation between Polish and Mongolian palaeontology may be impaired. Is this really the aim of *Nature's* policy?

Yours faithfully,

ZOFIA KIELAN-JAWOROWSKA

Academy of Sciences Institute of Palaeobiology, Warsaw, Poland.

Readers concerned that we may have seriously slighted Mongolian scientists are urged to read Vera Rich's original article. Ed.

Alpha-fetoprotein screening on a US regional basis

SIR — The future of pregnancy alpha-fetoprotein (AFP) serum screening in the United States (5 July, page 6) is dependent upon decisions from the political as well as the scientific communities. Intense pressure has been applied to the Food and Drug Administration (FDA) to restrict test reagent kit licensure to carefully monitored regional programme. Few such programmes currently exist, due to lack of financial support from major funding sources such as the Department of Health, Education and Welfare, thus placing the FDA in a difficult position.

A number of private and commercial laboratories in this country have produced their own reagents and now offer the AFP test for pregnancy. Such testing is legal and is not covered by FDA restrictions. In the absence of coordinated action by federal funding and licensing agents such testing will proliferate and its quality will be unpredicatable. Equally important, the ability to interpret and follow up properly on test results will be generally poor, especially in the absence of an integrated patient service programme. These issues have been extensively discussed at the 1977 and 1978 Scarborough Conferences.

Pilot programmes in Nassau County, New York and in Maine have demonstratred beyond doubt that AFP testing in pregnancy can be carried out successfully on a regional basis within the structure of the US health care system. There is no question that such testing, properly applied, represents a major step forward in the identification and management of a variety of high-risk pregnancies, including major malformations (e.g. anencephaly, spina bifida, omphalocele, congenital nephrosis), twins, molar pregnancies, missed abortions, fetal demise, and pregnancies at high risk for premature delivery. If the full potential for this testing is to be realized, it must be actively supported and carefully executed.

Towards that end, plans are being made for a third Scarborough Conference to be held in June 1980, and emphasis is to be placed on the process of regionalisation. We hope that government agencies will have taken purposeful and positive action by that time; representatives from that sector will be invited to participate.

Yours faithfully,

JAMES E. HADDOW
EDWARD M. KLOZA

Foundation for Blood Research, Scarborough, Maine, US.

Recombinant DNA and induced tumours

SIR, — In the editorial (7 June, page 461), in which you call on the US Congress to act on recombinant DNA legislation (in itself a questionable intervention by *Nature*), you base your recommendation, in part, on risk experiments which "have indicated hitherto unanticipated potential hazards (such as the ability of DNA strands to induce tumours in laboratory animals)". Since the "risk experiments" presumably referred to were from our laboratories, we would like to comment.

As part of the polyoma risk assessment experiment (*Science* **203**, 883 and 887; 1979), which was designed to monitor the possible transfer of potentially infectious DNA out of *E. coli* and into susceptible mammalian cells, we inoculated baby hamsters with polyoma virus DNA (Israel *et al.*, *J. Virol.* **29**, 990; 1979) and with polyoma DNA contained in recombinant molecules (Israel *et al.*, *Science*, in the press). In brief, the two types of polyoma DNA showed comparable oncogenicity; when contained in the *E. coli* K-12 host, which was the experimental system, the recombinant DNA did not induce any tumours.

First, it seems misleading to state that "DNA strands" can induce tumours, without the qualification that you are referring to DNA from a tumour virus. Second, this finding would have been "unanticipated" only by persons who both know little or nothing of tumour virology, and who did not even read the material. Tumourigenesis and cell transformation by DNAs from various tumour viruses, including polyoma virus, have been reported many times over the past 19 years; these findings are widely known, and are well referenced in our paper in the *Journal of Virology*, as well as in the publications cited there.

Since the example cited by *Nature* has no substance, we must wonder if there are any "unanticipated potential hazards" at all. Indeed, the 31 May issue (page 360) quotes one of us as saying "I do not know of a single piece of new data that has indicated that K-12 recombinant DNA research [meaning those experiments not prohibited by the US guidelines] could generate a biohazard." This remains our view, despite *Nature's* careless assertion to the contrary.

Major recombinant DNA policy recommendations based on uncritically accepted misstatements made by uninformed persons are only too familiar, but one would expect *Nature* to employ higher standards.

Yours faithfully,

WALLACE P. ROWE
MALCOLM A. MARTIN

Preparing oral rehydration salt solutions

SIR, — Even if packets of oral renydration salts are available (29 March, page 389), are illiterate village people capable of preparing the correct concentration of solution? If not, then they must be helped — in high concentrations the salts could be hazardous and in low concentrations they are useless. The ingredients, brown sugar, sugar, salt and sodium bicarbonate are available in most rural areas; but the 'pinch', spoon and drinking glasses are so variable that they cannot be reliably used for measuring.

The Indonesian spoon mentioned in the article is suitable for measuring the solids, but how is the fluid measured? The recommended beer bottle is not available in Muslim countries. I would, therefore, like to suggest that the UNICEF oralyte packet should contain a plastic bag, with a marked narrow neck like a bottle and instructions for measuring the fluid, and that the relevant agencies distribute cheap half-litre drinking glasses in remote villages where the UNICEF packets are not available. Three indentations should be made on the bottom of the glass: one for measuring each of sugar, salt and sodium bicarbonate. The level of the water required should be marked on the glass and instructions together with the limitations of oral rehydration should be engraved on it in local language.

The glasses should be distributed free or at a subsidised cost. They will usually be used for drinking water.

Yours faithfully,

MOSLEMUDDIN KHAN

International Centre for Diarrhoeal Disease Research, Bangladesh.

Erratum

In Norman Dombey's article (26 July, page 270) the sentence "So in a fast reactor of the design envisaged in CFR1 or Superphenix . . . there will be no overall negative Doppler coefficient" should conclude" . . . there will be an overall negative Doppler coefficient".

Hypercycles and the origin of life

from John Maynard Smith

PERHAPS the most difficult step to explain in the origin of life is that from the replication of molecules (RNA for example) in the absence of specific proteins, to the appearance of polymerases and other proteins involved in the replication of RNA and themselves coded for by that RNA. Suppose we start with a population of replicating RNA molecules. Without specific enzymes the accuracy of replication is low and hence the length of RNA which could be precisely replicated small. Before replication can be reasonably accurate, there must as a minimum be a specific polymerase, as well as synthetases and tRNAs, which in turn implies an RNA genome of considerable length. Thus, even if one supposes an initially very limited set of codons, one cannot have accurate replication without a length of RNA, say, 2,000 or more base pairs, and one cannot have that much RNA without accurate replication. This is the central problem discussed in a series of papers by Manfred Eigen and Peter Schuster (*Naturwissenschaften* **64**, 541; 1977; **65**, 7; 1978; **65**, 341; 1978), proposing the 'hypercycle' as a necessary intermediate stage.

First, imagine a population of replicating RNA molecules, lacking genetic recombination, but with a certain 'error' or 'mutation' rate per base replication. Very roughly, if more than one mutation occurred per molecular replication, the population would come to consist of a random collection of sequences. But if less than one mutation occurred per replication, and if one sequence was 'fitter' than others in the sense of being more stable and/or more easily replicated, then a population would arise whose sequences were centred around this optimal one. Such a population Eigen and Schuster call a molecular 'quasi-species'. If the mutation rate per replication was much less than one, and if fitness differences were large, most molecules would have the optimal sequence. As the mutation rate increased, the proportion of the population with the optimal sequence would fall, until a critical mutation rate was reached, above which sequences would be random.

The replication of RNA molecules in the absence of specific replicases has not yet been achieved in the laboratory; it may initially have depended on the presence of nonspecific random sequence polypeptides. At this stage, the error rate would depend solely on the energy levels of base pairing between G and C, and between A and U, and would be such that the maximum length of a quasi-species would be 10–100 base pairs; even this length would require the RNA to be G–C rich. In contrast, RNA replication by the enzyme coded for by the RNA phage Qβ is accurate enough to permit a genome of 1,000-10,000 base pairs, which would be sufficient to code for a primitive protein-synthesising machinery. The next stage in the evolution of accuracy of replication, achieved by prokaryotes, was the recognition and correction of mismatches in DNA replication, a process which depends on recognising which is the old strand and which the new. With such proof-correcting, a genome of at least 10^6 base pairs, and perhaps 10^8 - 10^9 base pairs, can be maintained. It is the gap between the 10–100 bases, without specific enzymes, and the 1,000–10,000 bases, with specific enzymes, that Eigen and Schuster aim to bridge.

To understand their proposal, imagine that you wish to replicate the message GOD SAVE THE QUEEN. Counting 5 bits per letter, this is a total of 75 bits, and a maximum of 25 bits per word. Supposed the error rate was, say, 1/50 per bit. You start with a population of messages, copy each of them with that error rate, and then discard half of the population, applying a rule of selection so that messages with many errors are more likely to be discarded. Despite this 'natural selection', the population would steadily accumulate errors. The mutation rate is too high.

Suppose, therefore, that after each replication you selected word by word, discarding half the quasi-species GOD, and similarly for each other word. Since no word contains as many as 50 bits, you could now maintain a meaningful message. However, there is an important reason why this is *not* an adequate model of the replication of a set of RNA molecules. Thus, to maintain complete messages you would have to ensure in each generation that you selected equal numbers (or approximately so) of each word. But suppose the words competed, as RNA molecules would compete for substrates. Then before long only one quasi-species

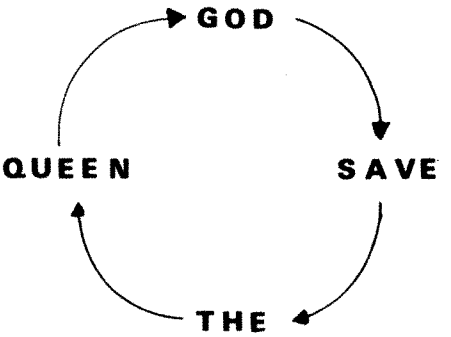

Fig. 1

Hence if the words are strung together into a single selected message (analogous to a single RNA molecule), the message is too long to replicate; if they are replicated separately, competition between the words destroys the message. You can escape from this dilemma by arranging the words in a 'hypercycle', as in Fig. 1. In this cycle, the *rate* (not the accuracy) of replication of SAVE is increased by the number of GODs, of THE by the number of SAVEs, of QUEEN by the number of THEs, and, coming full circle, of GOD by the number of QUEENs. Each word, or quasi-species, is selected independently, according to its own fitness. This is a hypercycle. It can be shown that only by linking together a set of replicating quasi-species in this cyclical way can the stability of the whole be maintained.
